High-speed GPIOs exist in this device.
- GPIO1-5 are standard-speed GPIOs that run off the IPG_CLK_ROOT, while GPIO6-9 are high-speed GPIOs that run at the AHB_CLK_ROOT frequency. See the table "System Clocks, Gating, and Override" in CCM chapter.
- Regular GPIO and high speed GPIO are paired (GPIO1 and GPIO6 share the same pins, GPIO2 and GPIO7 share, etc). The IOMUXC_GPR_GPR26-29 registers are used to determine if the regular or high-speed GPIO module is used for the GPIO pins on a given port.

12.2 Overview

The GPIO general-purpose input/output peripheral provides dedicated general-purpose pins that can be configured as either inputs or outputs.
When configured as an output, it is possible to write to an internal register to control the state driven on the output pin. When configured as an input, it is possible to detect the state of the input by reading the state of an internal register. In addition, the GPIO peripheral can produce CORE interrupts.

The GPIO is one of the blocks controlling the IOMUX of the chip.

**Figure 12-1. Chip IOMUX Scheme**

The GPIO functionality is provided through eight registers, an edge-detect circuit, and interrupt generation logic.
The eight registers are:

- Data register (GPIO_DR)
- GPIO direction register (GPIO_GDIR)
- Pad sample register (GPIO_PSR)
- Interrupt control registers (GPIO_ICR1, GPIO_ICR2)
- Edge select register (GPIO_EDGE_SEL)
- Interrupt mask register (GPIO_IMR)
- Interrupt status register (GPIO_ISR)

These registers are described in detail in the Register section.

Each GPIO input has a dedicated edge-detect circuit which can be configured through software to detect rising edges, falling edges, logic low-levels or logic high-levels on the input signals. The outputs of the edge detect circuits are optionally masked by setting the corresponding bit in the interrupt mask register (GPIO_IMR). These qualified outputs are OR'ed together to generate two one-bit interrupt lines:

- Combined interrupt indication for GPIOx signals 0 - 15
- Combined interrupt indication for GPIOx signals 16 - 31

In addition, GPIO1 provides visibility to each of its 8 low order interrupt sources (i.e. GPIO1 interrupt n, for n = 0 – 7). However, individual interrupt indications from other GPIOx are not available.

The GPIO edge detection is described further in Interrupt Control Unit.

The GPIO's overall functionality is described further in GPIO Functional Description.

### 12.2.1 Block Diagram

The GPIO subsystem contains multiple GPIO blocks, which can generate and control up to 32 signals for general purpose.

A block diagram of the GPIO is shown in Figure 12-2
12.2.2 Features

The GPIO includes the following features:

- General purpose input/output logic capabilities:
  - Drives specific data to output using the data register (GPIO_DR)
  - Controls the direction of the signal using the GPIO direction register (GPIO_GDIR)
  - Enables the core to sample the status of the corresponding inputs by reading the pad sample register (GPIO_PSR).
- GPIO interrupt capabilities:
  - Supports up to 32 interrupts
  - Identifies interrupt edges
  - Generates three active-high interrupts to the SoC interrupt controller
12.3 Clocks

The table found here describes the clock sources for GPIO.

Please see the CCM for clock setting, configuration and gating information.

12.4 GPIO Functional Description

This section provides a complete functional description of the block.

12.4.1 GPIO Function

A GPIO signal can operate as a general-purpose input/output when the IOMUX is set to GPIO mode. Each GPIO signal may be independently configured as either an input or an output using the GPIO direction register (GPIO_GDIR).

When configured as an output (GPIO_GDIR bit = 1), the value in the data bit in the GPIO data register (GPIO_DR) is driven on the corresponding GPIO line. When a signal is configured as an input (GPIO_GDIR bit = 0), the state of the input can be read from the corresponding GPIO_PSR bit.
12.4.2 GPIO pad structure

12.4.2.1 Input Driver

Input driver characteristics

- Selectable Schmitt trigger or CMOS input mode
- Keeper structure with buffer at the input receiver output to Core
- Receiver is tri-stated when I/O supply (OVDD) is powered down. (Keeper at receiver output keeps its previous state).

12.4.2.1.1 Schmitt trigger

The anti-jamming functionality of the Schmitt trigger is illustrated below.
12.4.2.1.2 Input keeper

A simple latch to hold the input value when OVDD is powered down, or the first inverter is tri-stated. Input buffer’s keeper is always enabled for all the pads.

12.4.2.2 Output Driver

Output driver characteristics

- Selectable CMOS or open-drain output type
• Selectable pull-keeper enable signal to enable/disable the pull-up/down and output keeper
• Selectable pull-up resistors of 22K, 47K, 100K and a pull-down resistor of 100KOhm. Unsilicided P+ poly resistor is used to limit resistance variation to within +/- 20%.
• Pull-up, pull-down, and pad keeper are disabled in output mode.
• Seven drive strengths in each operating mode
• Additional 2-bit slew rate control to select between 50, 100, and 200 MHz IO cell operation range with reduced switching noise

![Output Driver Functional Diagram](image)

**Figure 12-6. Output Driver Functional Diagram**

### 12.4.2.2.1 Drive strength

Drive strength selection can be used to make the impedance matched and get better signal integrity.

### 12.4.2.2.2 Output keeper

A simple latch to hold the input value.
12.4.2.2.3 PU / PD / Keeper Logic

When Keeper is enabled, the pull-up and pull-down are disabled, and the output value of the pad depends on the Keeper. The output keeper is powered by OVDD. When the core VDD is powered down or the first inverter is tri-stated, the pad’s state can be kept. Keeper and Pull can’t be enabled together.

12.4.2.2.4 Open drain

Open drain is a circuit technique which allows multiple devices to communication over a single wire bi-directionally. Open drain drivers usually operate with an external or internal pull-up resistor that holds the signal line high until a device sinks enough current to pull the line low, usually used for a bus with multiple devices.

Figure 12-7. Keeper functional diagram
If internal pull-up resistor (Rpu) is used, output level will depend on OVDD1

If external Rpu is used, output level will depend on OVDD2

Figure 12-8. Output buffer in open drain mode

### 12.4.3 GPIO Programming

#### 12.4.3.1 GPIO Read Mode

The programming sequence for reading input signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUX Controller (IOMUXC)).
2. Configure GPIO direction register to input (GPIO_GDIR[GDIR] set to 0b).
3. Read value from data register/pad status register.

A pseudocode description to read [input3:input0] values is as follows:

```c
// SET INPUTS TO GPIO MODE.
write sw_mux_ctl_<input0>_<input1>_<input2>_<input3>, 32'h00000000
// SET GDIR TO INPUT.
write GDIR[31:4,input3_bit, input2_bit, input1_bit, input0_bit,] 32'hxxxxxxxxx0
// READ INPUT VALUE FROM DR.
read DR
// READ INPUT VALUE FROM PSR.
read PSR
```

**NOTE**

While the GPIO direction is set to input (GPIO_GDIR = 0), a read access to GPIO_DR does not return GPIO_DR data. Instead, it returns the GPIO_PSR data, which is the corresponding input signal value.

#### 12.4.3.2 GPIO Write Mode

The programming sequence for driving output signals should be as follows:

1. Configure IOMUX to select GPIO mode (Via IOMUXC), also enable SION if need to read loopback pad value through PSR
2. Configure GPIO direction register to output (GPIO_GDIR[GDIR] set to 1b).
3. Write value to data register (GPIO_DR).
A pseudocode description to drive 4'b0101 on [output3:output0] is as follows:

```c
// SET PADS TO GPIO MODE VIA IOMUX.
write sw_mux_ctl_pad_<output[0-3]>.mux_mode, <GPIO_MUX_MODE>
// Enable loopback so we can capture pad value into PSR in output mode
write sw_mux_ctl_pad_<output[0-3]>.sion, 1
// SET GDIR=1 TO OUTPUT BITS.
write GDIR[31:4,output3_bit,output2_bit, output1_bit, output0_bit], 32'hxxxxxxxF
// WRITE OUTPUT VALUE=4'b0101 TO DR.
write DR, 32'hxxxxxxx5
// READ OUTPUT VALUE FROM PSR ONLY.
read_cmp PSR, 32'hxxxxxxx5
```

### 12.4.4 Interrupt Control Unit

In addition to the general-purpose input/output function, the edge-detect logic in the GPIO peripheral reflects whether a transition has occurred on a given GPIO signal that is configured as an input (GDIR bit = 0). The interrupt control registers (GPIO_ICR1 and GPIO_ICR2) may be used to independently configure the interrupt condition of each input signal (low-to-high transition, high-to-low transition, low, or high). For information about GPIO_ICR1 and GPIO_ICR2 settings, see the Register section.

The interrupt control unit is built of 32 interrupt control subunits, where each subunit handles a single interrupt line.

### 12.5 GPIO Register Descriptions

There are eight 32-bit GPIO registers. All registers are accessible from the IP interface. Only 32-bit access is supported.

The GPIO memory map is shown in the following table.

#### 12.5.1 GPIO Memory map

GPIO\textsubscript{n} base address: 401B\_8000h + (n-1)×4000h, where \(n\) is from 1 to 4.

GPIO\textsubscript{5} base address: 400C\_0000h.

GPIO\textsubscript{n} base address: 4200\_0000h + (n-6)×4000h, where \(n\) is from 6 to 9.
## 12.5.2 GPIO data register (DR)

### 12.5.2.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>GPIO data register (DR)</td>
<td>0h</td>
</tr>
</tbody>
</table>

### 12.5.2.2 Function

The 32-bit GPIO_DR register stores data that is ready to be driven to the output lines. If the IOMUXC is in GPIO mode and a given GPIO direction bit is set, then the corresponding DR bit is driven to the output. If a given GPIO direction bit is cleared, then a read of GPIO_DR reflects the value of the corresponding signal. Two wait states are required in read access for synchronization.

The results of a read of a DR bit depends on the IOMUXC input mode settings and the corresponding GDIR bit as follows:

- If GDIR[n] is set and IOMUXC input mode is GPIO, then reading DR[n] returns the contents of DR[n].
- If GDIR[n] is cleared and IOMUXC input mode is GPIO, then reading DR[n] returns the corresponding input signal's value.
• If GDIR\[n\] is set and IOMUXC input mode is not GPIO, then reading DR\[n\] returns the contents of DR\[n\].
• If GDIR\[n\] is cleared and IOMUXC input mode is not GPIO, then reading DR\[n\] always returns zero.

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>DR</td>
</tr>
</tbody>
</table>
| DR    | Data bits. This register defines the value of the GPIO output when the signal is configured as an output (GDIR[n]=1). Writes to this register are stored in a register. Reading GPIO_DR returns the value stored in the register if the signal is configured as an output (GDIR[n]=1), or the input signal's value if configured as an input (GDIR[n]=0).  
**NOTE:** The I/O multiplexer must be configured to GPIO mode for the GPIO_DR value to connect with the signal. Reading the data register with the input path disabled always returns a zero value. |

### 12.5.3 GPIO direction register (GDIR)

#### 12.5.3.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>GDIR</td>
<td>4h</td>
</tr>
</tbody>
</table>
12.5.3.2  Function

GPIO_GDIR functions as direction control when the IOMUXC is in GPIO mode. Each bit specifies the direction of a one-bit signal. The mapping of each DIR bit to a corresponding SoC signal is determined by the SoC's pin assignment and the IOMUX table. For more details consult the IOMUXC chapter.

<tr>
<td>31-0</td>
<td>GDIR</td>
</tr>
<tr>
<td>GDIR</td>
<td>GPIO direction bits. Bit n of this register defines the direction of the GPIO[n] signal.</td>
</tr>
</tbody>
</table>

NOTE: GPIO_GDIR affects only the direction of the I/O signal when the corresponding bit in the I/O MUX is configured for GPIO.

0b - GPIO is configured as input.
1b - GPIO is configured as output.

12.5.4  GPIO pad status register (PSR)

12.5.4.1  Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>PSR</td>
<td>8h</td>
</tr>
</tbody>
</table>
12.5.4.2 Function

GPIO_PSR is a read-only register. Each bit stores the value of the corresponding input signal (as configured in the IOMUX). This register is clocked with the ipg_clk_s clock, meaning that the input signal is sampled only when accessing this location. Two wait states are required any time this register is accessed for synchronization.

<td>ISR</td>
<td>18h</td>
</tr>
</tbody>
</table>

12.5.8.2 Function

The GPIO_ISR functions as an interrupt status indicator. Each bit indicates whether an interrupt condition has been met for the corresponding input signal. When an interrupt condition is met (as determined by the corresponding interrupt condition register field), the corresponding bit in this register is set. Two wait states are required in read access for synchronization. One wait state is required for reset.

Chapter 13
Clock and Power Management

13.1 Introduction

This chapter describes the Clock and Power Management architecture of the SoC.

The chip targets applications where low power consumption, long battery life, always-on and instant-on capabilities are paramount, and where there is no need for active cooling. To achieve these capabilities, the primary focus of the chip's design is reducing current consumption as much as possible, while simultaneously enabling the maximum level of peak performance and a balanced level of sustained performance for target applications. To achieve this, the chip architecture uses a wide range of power-management techniques and their combinations for maximum system design flexibility.

This chapter contains information about:

- Structural components of the power and clock management systems of the chip
- Power, clock and thermal management techniques supported by the chip

All given numerical values are typical or examples. For accurate values one should refer to the datasheet.

13.2 Device Power Management Architecture Components

To provide a clean and versatile architecture supporting a wide range of power-management techniques, clocks, and power rails are managed resources.

For each rail, two levels of management are defined: the first level is centralized or SoC-level resource management, and the second is a local or "module level" resource management.

The high level architectural view of the clock, power and thermal management system of the chip is presented in the figure below.
13.2.1 Centralized components of clock generation and management

Centralized components of the clock generation and management sub-system are implemented in the following blocks:

- **CCM (Clock Control Module):** The CCM module provides control for primary (source level) and secondary (root level) clock generation, division, distribution, synchronization, and coarse-level gating. See Clock Controller Module (CCM) for
information on the CCM architecture, functional description and programming model.  
- LPCG (Low Power Clock Gating): This module distributes the clocks to all blocks in the SoC and handles block level software-controllable and automated clock gating. See Clock Controller Module (CCM) for information on the LPCG architecture and functional description.

### 13.2.2 Centralized components of power generation, distribution and management

Centralized components of the power generation, distribution and management sub-system are implemented in the following blocks:

- Power Management Unit (PMU). See Power Management Unit (PMU) for information on the PMU architecture, functional description and programming model.
- General Power Controller (GPC). See General Power Controller (GPC) for information on the GPC architecture, functional description and programming model.
- On Chip DC-DC regulator. See the DCDC chapter for more detailed information.

### 13.2.3 Reset generation and distribution system

Power and clock management are accompanied with an appropriate reset generation and distribution system, centralized functions of which are implemented by the System Reset Controller (SRC).

### 13.2.4 Power and clock management framework

Together, the modules listed above provide enhanced power-management features with centralized control for the clock, reset, and power-management signals on the SoC.

The centralized management framework defines the managed components of the power-management architecture. These components are called the clock, power, and voltage domains.

**NOTE**

A domain is a group of modules or functional blocks that share a common resource entity (for example, common clock root, common power source, or a common power switch). The software component managing shared resources should take
into account the joint constraints of all the modules belonging to that resource domain.

13.3 Clock Management
13.3.1 Centralized components of clock management system

The clock generation and management system is built around the CCM and LPCG blocks.

A high level block diagram of the clock management system in the SoC environment is shown in the following figure.

![Clock Management System Diagram]

**Figure 13-2. Clock Management System**

13.3.2 Clock generation

The clock generation section includes the components detailed in the following sections.
13.3.2.1 Crystal Oscillator (XTALOSC)

The Crystal Oscillator block is comprised of both the high frequency oscillator (typical frequency is 24 MHz) and the low frequency real time clock oscillator (typical frequency of 32.768 KHz). Each of these oscillators is implemented as a biased amplifier that, when combined with a suitable external quartz crystal and external load capacitors, implements an oscillator. See Crystal Oscillator (XTALOSC) for details of the XTALOSC block.

**NOTE**
1. The 24 MHz XTALOSC can be the external clock source of SYSTICK. Hardware divides this down to 100KHz before it reaches SYSTICK.
2. If XTALOSC24M_LowPwr_CTRLn[OSC_SEL] is set to ROSC, the chip's 24MHz clock will be from the 24MHz RCOSC. In this case, the RCOSC should be enabled properly beforehand.

13.3.2.2 PLLs

Seven PLLs are included in the clock generation section. Two of these PLLs are each equipped with four Phase Fractional Dividers (PFDs) in order to generate additional frequencies.

**NOTE**
Each PFD works independently by interpolating the VCO of the PLL to which it is connected. It effectively takes the PLL VCO frequency and produces 18/N x Fvco at its output where N ranges from 12 to 35. PFD is a completely digital design with no analog components or feedback loops. The frequency switch time is much faster than a PLL because keeping the base PLL locked and changing the integer N only changes the logical combination of the interpolated outputs of the VCO. Note that the PFD not only enables faster frequency changes than a PLL, but also allows the configuration to be safely changed "on-the-fly" without going through the output clock disabling/enabling process.

The seven PLLs are listed below:

- PLL1 (also referred to as ARM_PLL) - This is the PLL clocking the Arm core complex. It is a programmable integer frequency multiplier capable of output
frequency of up to 1.3 GHz. Note that this frequency is higher than the maximum chip supported frequency.

- PLL2 (also referred to as System_PLL or 528_PLL) - PLL2 runs at a fixed multiplier of 22, producing 528 MHz output frequency with 24 MHz reference from XTALOSC. Besides the main output, this PLL drives four PFDs (PLL2_PFD0...PLL2_PFD3). The main PLL2 output and its PFD outputs are used as inputs for many clock roots. These do not require exact/constant frequency and can be changed as a part of dynamic frequency scaling procedure. Typically, this PLL or its PFDs are a clock source for internal system buses, internal processing logic, SDRAM interface, NAND/NOR interface modules, etc.

- PLL3 (also referred to as USB1_PLL) - PLL3 is used in conjunction with the first instance of USB PHY (USBPHY1, also known as OTG PHY). This PLL drives four PFDs (PLL3_PFD0...PLL3_PFD3) and runs at a fixed multiplier of 20. This results in a VCO frequency of 480 MHz with a 24 MHz oscillator. The main PLL3 output and its PFD outputs are used as inputs for many clock roots that require constant frequency, such as UART and other serial interfaces, audio interfaces, etc.

- PLL4 (also referred to as an Audio PLL) - This is a fractional multiplier PLL used for generating a low jitter and high precision audio clock with standardized audio frequencies. The PLLs oscillator frequency range is from 650 MHz to 1300 MHz, and the frequency resolution is better than 1 Hz. This clock is mainly used as a clock for serial audio interfaces and as a reference clock for external audio codecs. It is equipped with a divider on its output and can generate divided by 1, 2 or 4 from the PLL VCO frequency.

- PLL5 (also referred to as a Video PLL) - This is a fractional multiplier PLL used for generating a low jitter and high precision video clock with standardized video frequencies. The PLLs oscillator frequency range is from 650 MHz to 1300 MHz, and the frequency resolution is better than 1 Hz. This clock is mainly used as a clock for display and video interfaces. It is equipped with dividers on its output and can generate clock divided by 1, 2, 4, 8 or 16 from the PLL VCO frequency.

- PLL6 (also referred to as ENET_PLL) - This PLL implements a fixed 20+(5/6) multiplier. With a 24 MHz input, it has a VCO frequency of 500 MHz. This PLL is used to generate:
  - 50 or 25 MHz for the external ethernet interface.
  - 125 MHz for reduced gigabit ethernet interface.
  - 100 MHz for general purposes.

- PLL7 (also referred to as USB2_PLL) - This PLL provides clock exclusively to USB2 PHY (USBPHY2, also known as OTG PHY). It runs at a fixed multiplier of 20, resulting in a VCO frequency of 480 MHz with a 24 MHz oscillator.
13.3.2.2.1 General PLL Control and Status Functions

Each PLLs configuration and control functions are accessible individually through its PFDs and global configuration and status registers.

Reference input clock for any of the PLLs could be selected individually by the BYPASS_CLK_SRC field of the PLL control register. See CCM Analog Memory Map/ Register Definition for more information.

Each of the PLLs could be individually configured to "Bypass", "Output disabled" and "Power Down" modes.

When configured in "Bypass" PLL pass directly its input reference clocks to the PLL output. Bypassing the PLL is done by setting the BYPASS bit in the control register. For the PLL equipped with PFDs the input reference clock is also bypassed to all PFDs outputs.

When configured in output disabled mode (ENABLE=0), the PLL's output is completely gated and there is neither a bypass clock nor PLL generated clock that propagates to PLL output. Each PLL output has an individual "Output Enable" control bit. The PFDs are gated by the ENABLE bit of their associated PLL. Each PFD does have an associated clock gate bit that can be used to turn it off individually.

When configured in "Power Down mode" most of the PLL circuitry is switched off. Neither main PLL output nor PFD outputs are available in this mode.

When the related PLL is powered up from the power down state or made to go through a relock cycle due to PLL reprogramming, it is required that the related PFDx_CLKGATE bit in CCM_ANALOG_PFD_480n or CCM_ANALOG_PFD_528n, be cycled on and off (1 to 0) after PLL lock. The PFDs can be in the clock gated state during PLL relock but must be clock un-gated only after lock is achieved. See the engineering bulletin, Configuration of Phase Fractional Dividers (EB790) at www.nxp.com for procedure details.

Individual PLL status is reflected in "PLL Lock" bits of the PLL control registers. PLL enable logic which monitors the register value change is implemented to gate off the PLL outputs during the "lock in" period.

Outputs are generated to be sent out by monitoring the individual PLL lock flags and filtering out any random initial edges.

Individual PLL Lock ready flags are first "ORED" with "enables" and then "ANDED" together to generate the global PLL lock ready flag that reflects status of all PLLs enabled in certain moment.
CCM Memory Map/Register Definition and CCM Analog Memory Map/Register Definition contains detailed descriptions of the memory mapped registers and control functions of the clock generation sub-module.

13.3.2.3 CCM

CCM includes:

- Clock root generation logic - This sub-block provides the registers that control most of the secondary clock source programming, including both the primary clock source selection and the clock dividers. The clock roots are each individual clocks to the core, system buses (AXI, AHB, IPG) and all other SoC peripherals, among those are serial clocks, baud clocks, and special functional clocks. Most of clock roots are specific per module.
- CCM, in coordination with GPC, PMU and SRC, manages the Power modes, namely RUN, WAIT and STOP modes. The gating of the peripheral clocks is programmable in RUN and WAIT modes.

CCM manages the frequency scaling procedure for:

- Arm core clock - "on the fly" without clock interruption, by either shifting between PLL sources PLL clock change or by changing the divider ratio.
- Peripheral root clock - by using programmable divider. The division factor can change on the fly without loss of clocks.

NOTE

On-the-fly frequency changing for synchronous interfaces like serial audio interfaces, video and display interfaces, or general purpose serial interfaces (e.g. UART, CAN) may cause synchronization loss and should not be done.

13.3.2.4 Low Power Clock Gating unit (LPCG)

The LPCG block receives the root clocks from CCM and splits them to clock branches for each block. The clock branches are individually gated clocks.

The enables for those gates can come from three sources:

- Clock enable signal from CCM - This signal is generated depending on the power mode the system is in. For each power mode, it is defined in the software using the configuration of the CGR bits in CCM.
• Clock enable signal from the block - This signal is generated by the block based on its internal logic. Not every enable signal from the block is used. Each clock enable signal from the block can be overridden based on the programmable bit in CCM.
• Clock enable signal from the reset controller (SRC) - This signal will enable the clock during the reset procedure.

13.3.3 Peripheral components of clock management system

13.3.3.1 Interface and functional clock

Each block within the SoC has specific clock input characteristic requirements. Based on the characteristics of the clocks delivered to modules, the clocks are divided into two categories: bus interface clocks and functional clocks.

The bus interface clocks have the following characteristics:

• They ensure proper communication between any block/subsystem and the system buses.
• In most cases, they supply the system interface and configuration registers of the block.
• A typical block has one system bus clock, but blocks with multiple interface clocks may also exist (that is, when a block is connected to multiple buses).
• The bus interface clocks are always fed by the outputs of the CCM/LPCG.
• Clock management for this type of clock is always implemented at the system level because it requires coordinated clock management between the block and system buses.

Functional clocks have the following characteristics:

• They supply the functional part of a block or a subsystem.
• Typically, these clocks are completely asynchronous and independent from the bus interface clock of the same block.
• A block can have one or more functional clocks. Some functional clocks are mandatory, while others are optional for its functioning. A block needs its mandatory clock(s) to be operational. The optional clocks are used for specific features and can be shut down without stopping the block activity.
• The functional clocks are fed either by a CCM/LPCG block functional clock output, or by some other clock source, such as a clock output of another block or an external signal coming from IOMUX.
13.3.3.2 Block level clock management

Each block in the system may also have specific clock requirements. Certain module clocks must be active when operating in some specific modes, or may be gated in some others. Generally, the activation and gating of the module clocks are managed by LPCG. Hence, the LPCG block must be programmed properly and, in case of hardware controllable clock gating, peripheral module should provide signals indicating when to activate and when to gate the module clocks.

The LPCG block differentiates the clock-management behavior for device modules based on whether the block can initiate transactions on the device interconnect (called master module), or if it cannot initiate transactions and only responds to the transactions initiated by the master (called slave module). Thus, two hardware-based clock-management protocols are used:

- Master protocol - Clock-management protocol between the CCM/LPCG and blocks that can be bus master
- Slave protocol - Clock-management protocol between the CCM/LPCG and slave modules

13.3.3.2.1 Master clock protocol

This protocol is used to indicate that a master module is ready to initiate a transaction on the device interconnect and requests specific (both functional and interface) clocks. The CCM/LPCG block ensures that the required clocks are active when the master module requests that the CCM/LPCG enable them. The module is said to be functional after the required clocks are activated.

Similarly, when the master module no longer requires the clocks, it informs the LPCG/CCM block and the LPCG/CCM can then gate the clocks to the module and all the clock precedents that are not used by other blocks. The master module is then said to be in clock-gated or partially clock gated mode.

Examples of module supporting master clock protocol USDHC. Please see details in chapters describing these modules and in the CCM enable override register (CCM_CMEOR).

13.3.3.2.2 Slave clock protocol

This hardware protocol allows CCM to control the state of a slave module. CCM informs the slave module, through assertion of a stop/change request, when its clocks (both interface and functional) can be changed or gated. The slave acknowledges the request and CCM is then allowed to gate or change the clocks to the block.
Similarly, a clock-gated slave module may need to be woken up because of some event or a service request from a master module. In this situation, CCM enables the clocks to the module and then de-asserts the stop request to signal the module to wake up.

Examples of modules supporting slave clock protocol are CAN, and GPT. Please see details in chapters describing these modules and in the CCM Module Enable Override Register (CCM_CMEOR). See CCM Memory Map/Register Definition for more details.

The protocol in both "master" and "slave" cases is completely hardware-controlled, but software should configure the clock management behavior for the module in two places: in the CCM registers associated with the block and in the block configuration registers.

### 13.3.3.3 Clock Domain(s)

A clock domain is a group of blocks fed by clock signals controlled by the same clock controls in CCM. By gating the clocks in a clock domain, the clocks to all the blocks belonging to that clock domain can be gated/activated, either by software control or by hardware control associated with block activity. Thus, a clock domain allows efficient control of the dynamic power consumption of the domain.

The device is partitioned into multiple clock domains and each clock domain is controlled by an associated group of clock gating cells within the LPCG block. This allows the CCM/LPCG to individually activate and gate each clock domain of the system.

### 13.3.3.4 Domain level clock management

The domain clock manager can automatically (based on hardware conditions) and manage the bus interface clocks within the clock domain. The functional clocks within the clock domain are managed through software settings.

### 13.3.3.5 Domain dependencies

A domain dependency is a hierarchical relationship between two clock domains. Clock domain "X" is said to depend on a clock domain "Y" when a block in clock domain "Y" provides services (or even just a clock) to a block in clock domain "X". As a result, clock domain "Y" must be active whenever clock domain "X" is active.

The dependency between two clock domains may also exist if one clock domain serves to ensure communication between two blocks (for example, the clock domain of the device interconnect).
13.4 Power management

13.4.1 Centralized Components of Power Management System

The power generation and management system is built around the PMU and GPC blocks. A high level block diagram of the power management system in the SoC environment is shown in the figure below.

![Diagram of Power Management System](image)

**Figure 13-3. Power Management System**

13.4.1.1 Integrated PMU

The first component of the power management system, referred to as the integrated PMU, is designed to simplify the external power interface.
It consists of a set of secondary power supplies that enable SoC operations from just two or three primary supplies. The high level block diagram of the power tree, utilizing the integrated PMU, is shown below.

![SOC Power Tree Diagram]

Figure 13-4. SOC Power Tree

The integrated PMU includes the following components:

- On-chip DCDC regulator
- Two Analog LDO regulators
- USB LDO
- SNVS regulator

See Power Management Unit (PMU) for further details on integrated PMU functional description and programmability.

13.4.1.1.1 DCDC Regulator

The DCDC regulator includes the following features:

- Adjustable (25 mV per step) high efficiency regulator
- Supports 3.3 V (±10%) input voltage
- Output ranged in 0.9 V~1.3 V
- Supports nominal run, low power standby and off modes
- Supports 0.9 V~1.3 V output in run mode
• Supports 0.9 V~1.0 V output in standby mode
• Over current and over voltage detection

These modes allow the regulator to implement voltage scaling and power gating, and allow bypass when an external high power efficient regulator is used as a direct source for some of the SoC loads.

The DVFS (Dynamic Voltage and Frequency Scaling) in a typical cost/complexity optimized application is considered by means of an internal DCDC. The DCDC workpoint can be dynamically adjusted according to the system's working frequency requirement.

13.4.1.1.2 Analog LDO regulators

There are two analog LDO regulators used for general system purposes:

• LDO_1P1 - The LDO_1P1 (VDD_HIGH_IN, NVCC_PLL) linearly regulates down a higher supply voltage (2.8V-3.3V) to produce a nominal 1.1V output voltage. This regulator supplies digital portions of USB PHYs, PLLs, and the internal 24 MHz oscillator.

• LDO_2P5 - The LDO_2P5 (VDD_HIGH_IN, VDD_HIGH_CAP) linearly regulates down a higher supply voltage (2.8V-3.3V) to produce a nominal 2.5V output voltage. The regular 2.5V LDO is combined with an alternate self-biased low-precision weak regulator which can be enabled for applications that need to keep the 2.5V output voltage alive during low power modes, where the main regulator and its associated global bandgap reference module are disabled to save power. The output of this weak-regulator is not programmable and is a function of its input power supply as well as its load current. Typically with a 3V input power supply, the weak-regulator output is 2.525V and its output impedance is approximately 40Ohm. Special procedure is recommended to move load back and forth between the main and low power (weak) regulators. This regulator supplies most of the analog circuitry of the integrated PHYs, and other analog and mix signal components integrated into the SoC.

13.4.1.1.3 USB LDO

The USB_LDO linearly regulates down the USB VBUS input voltages (typically 5V) to produce a nominal 3.0V output voltage. This regulator has a built in power-mux that allows the user to run the regulator from either one of the VBUS supplies when both are present. If only one of the VBUS voltages is present, the regulator automatically selects that supply. Current limit is also included to help the system keep the in-rush current within limits as required in USB 2.0 specification. This regulator supplies only low speed and full speed transceivers of USB PHYs.
13.4.1.4 SNVS regulator

The SNVS regulator takes the SNVS_IN supply and generates the SNVS_CAP supply, which in turn powers the real time clock and low power section of the SNVS modules. If VDDHIGH_IN is present, then the SNVS_IN supply is internally shorted to the VDDHIGH_IN supply to allow coin cell recharging if necessary.

13.4.1.2 GPC - General Power Controller

The GPC block includes the sub-blocks listed here.

- Power Gating Controller (PGC) - This sub-block of GPC has the following functions:
  - Provides the user with the ability to switch off power to a target subsystem.
  - Generates power-up and power-down control sequences. This includes interaction with CCM/LPCG and SRC, and control for clock and reset generation for power domains affected by power gating.
  - Provides programmable registers that adjust the timing of the power control signals.
  - Controls the CPU power domain and Memory sub-domain (PDRAMx).
- Wake-up interrupt controller - This controller initiates the system wake-up from low power modes when only low frequency real time clock remains active, and thus the Generic Interrupt Controller (GIC) can not handle synchronous interrupt signals. Additional features are as follows:
  - Supports up to 160 interrupts
  - Provides an option to mask/unmask each interrupt
  - Detects interrupts and generates the wake up signal

See General Power Controller (GPC) for further details on GPC, its sub-blocks, and information on its functional description and programmability.

13.4.1.3 SRC - System reset Controller

The reset controller is responsible for the generation of all reset signals and boot configuration decoding.

It determines the source and the type of reset, such as POR and COLD, and performs the necessary reset signal qualifications. SRC is capable of generating reset sequences in the following conditions:
• in interaction with external PMIC, based on external POR_B signal and "power ready" signals generated by the integrated PMU
• or in interaction with the integrated PMU only, based on its "power ready" signal.

Based on the type of reset, the reset logic generates the reset sequence for either the entire SoC or for the blocks that are power-gated.

See System Reset Controller (SRC) for further details on SRC functional description and programmability.

13.4.1.4 Power domain(s)

A power domain is a group of blocks or sub-blocks fed by power sources controlled by the same power controls in GPC.

Some power domains can be split into a logic sub-domain and a memory sub-domain. The memory sub-domain in such case may contain two entities:

- Memory array(s) - Powered by a dedicated voltage rail enabling memory retention while core is OFF.
- Memory interface logic - Powered by the same voltage source as the logic sub-domain of the power domain.

Signals crossing power domain boundaries or sub-domain boundaries are passed through proper isolation and/or level-shifting cells to ensure robust operations of the SoC when some of domains are power gated or working at a reduced voltage.

The following figure shows the power domain interface within the system.
13.4.1.4.1 Power distribution

The power distribution tree is comprised of multiple power domains. The main power domains are:

- Arm - The Arm domain contains the Arm Core platform. This domain can be supplied from internal or external controllable regulator.
- FlexRAM memory array - Bank0 to Bank15 of FlexRAM.
- OCRAM2 memory array - The OCRAM2 memory array is partitioned into 2 sub-domains: 64KB always on domain (also known as PDRET domain, starting from address 2020_0000h), 448KB PDRAM1 domain.
- SNVS/RTC low power domain - The SRTC (Secure Real Time Counter) domain contains only counter, comparator and compared data of the on-chip RTC. This domain should be supplied from an external single cell LiION battery and/or an external pre-regulated power supply. This SNVS domain also contains Low Power State Retention (LPSR) GPIO, IOMUX, and LPSR general purpose register.
- Analog domain - The analog domain contains the PLLs, LDOs and USB PHY. The domain supplies should be constant to allow continuous clock during any dynamic voltage scaling techniques. The digital supply should be provided from an internal regulator, and can be combined with the memory array supply. The analog supply should be provided from internal low noise regulator.
- Main SoC logic - The main SoC logic domain contains the rest of the logic of the SoC. It is supplied by the same power supply as the Arm Core Platform.

From a DVFS and Power Gating standpoint, the following digital logic domains are affected:

- Arm Core Platform - DVFS and power gating.
- FlexRAM memories - DVFS and power gating.
- PDRAM1 (within OCRAM2) memories - DVFS and power gating.
- Main SoC logic - DVFS, no power gating.

13.4.1.4.2 Domain memory and domain logic state retention in case of power gating

The following is the list of relevant memories and logic domains with the description of their state-retention support.

**NOTE**

For more detailed information, see the table "Low Power Mode Definition" in this chapter.

- Arm Core Platform logic - the software state retention for all logic is implemented in this domain and L1 cache memories. Software state retention means that the content
of relevant registers should be stored in some memory retaining its state (OCRAM for example) while the logic domain is power-gated.

• PDRET memories - hardware state-retention in all power modes except SNVS mode.
• FlexRAM PDRAM0 memories - hardware state-retention. When Arm core is power gated, PDRAM0 memories can be either left on with its content retained or power gated together with the core.
• FlexRAM PDRAM1 memories - can be powered gated (together) independently of Arm core power gating.
• SoC - hardware state-retention.
• SNVS_LP - hardware state-retention even when SoC supplies are removed.

13.4.1.4.3 Power Gating Domain Management

The following bullets provide the sequence required for power-gating the relevant power-domains:

13.4.1.4.3.1 Arm Core Platform

1. Copy through software all the Core configuration registers to a powered-on memory
2. Configure the GPC/PGC CPU registers in PGC Memory Map/Register Definition as follows to power-down the core on the next "WFI" instruction:
   • Configure the GPC/PGC PGC_CPU_PDNSCR Register ISO and ISO2SW bits. The ISO field determines the delay between the power-down request and enabling the platform isolation. The ISO2SW field determines the delay between the platform isolation and the actual power-off switch to the supplies.
   • Configure the GPC/PGC PGC_CPU_PUPSCR Register SW and SW2ISO bits. The SW field determines the delay between the power-up request and the actual power-up of the supplies. The SW2ISO field determines the delay between asserting power toggle and negating platform isolation.
   • Configure the GPC PGC PGC_CPU_CTRL PCR bit to allow the power down of the platform
   • Arm Core Platform should execute a "WFI" instruction.

Figure 13-6. Arm Core Platform isolation and power on switch flow
13.4.1.4.3.2 SoC

For additional power reduction it is possible to do the following:

- Power-down the internal oscillator by configuring the following bits CCM_CCR[COSC_EN] (CCM Memory Map/Register Definition). This can be done only in case there is no dependency on 24 MHz XTAL for wake-up.
- It is possible to turn off and turn on the PMIC supplies to the SoC even when the SoC supplies are off. Since SNVS_LP is powered through an "always on" supply, configuring the SNVS_LP DP_EN to "1" allows changing the PMIC_ON_REQ pad (SoC on/off supply indication to the PMIC) through the ONOFF pad.

13.4.1.4.4 Power Gating domain dependencies

There are 3 power domains that need to be isolated in different power-down cases:

- Arm Core Platform and PDRAMx - Isolation needs to be enabled before power-down. This is taken care of automatically after CCM and PGC are configured and the Arm Core Platform executes the "WFI" instruction.
- SNVS_LP - Different from the 2 domains above, the SNVS_LP isolation isolates the signals coming from the SoC to the SNVS_LP. This is required for saving the contents of the SNVS_LP (such as the real-time clock). The isolation is activated in 2 ways:
  - Automatically through the power-fail detector in the PMU
  - Through software configuration

![Diagram of SoC Voltage Domain, isolation cells, and voltage level shifters]

**Figure 13-7. Isolation cells and Voltage level shifters placing**
13.4.1.5  Voltage domains

The list found here states the different voltage domains and their scalability in regarding to power-saving in dynamic and static scenarios.

- SoC domain: including Core Platform, FlexRAM memories and SoC logic - Scalable voltage in both dynamic and static scenarios
- ANALOG components including PLLs - Fixed voltage
- I/O - Fixed voltage
- SNVS_LP - Fixed voltage

13.4.1.6  Voltage domain management

13.4.1.6.1  Dynamic

13.4.1.6.1.1  Voltage Scaling

A simplistic way to reduce power consumption in dynamic scenarios is to scale down the Arm and SoC voltage according to the allowed voltage points and corresponding frequencies specified in datasheet.

13.4.1.6.2  Static

13.4.1.6.2.1  Standby Leakage reduction (SLR)

Standby leakage reduction is a power-management technique utilizing:

- Reduced supply voltage for relevant domains

With SLR, the device switches into low-power active system modes automatically or in response to user requests during system Stop, Wait, or DSM modes (that is, in situations when no application is started and no system activity is presented).

When applying SLR, the system remains in the lowest static power mode while retaining logic and memory states. This technique trades static power consumption for wake-up latency while maintaining fast system response time suitable for most applications.

See CCM Control Register (CCM_CCR), CCM Low Power Control Register (CCM_CLPCR) and PMU Miscellaneous Register 0 (PMU_MISC0) for further details on SLR programmability options.

The following describes the flow for applying standby voltage:
• Configure the external PMIC standby voltage, refer to chip datasheet.
• Configure CCM_CCR[RBC_EN] bits to bypass and disable PMU regulators in the next Arm "WFI" execution.
• Configure CCM_CCR[REG_BYP_COUNT] bits to allow proper voltage restoration by the external PMIC when exiting standby.
• Arm Core Platform executes the "WFI" instruction that completes the software sequence putting the SoC into low power mode

13.4.1.7 System domains layout

The following table describes the different power modes.

For more information regarding the low-power application design points on i.MX RT series, see the application note AN12085: How to use i.MX RT Low Power Feature.

NOTE
The IDLE, SUSPEND and SNVS are usually referred as low power mode.

• IDLE Modes: CPU in WFI state, some portion of the chip can be clock gated or power gated. The chip can wakeup from this mode from IRQ with a very short latency. IDLE mode is entered automatically from RUN mode when CPU executes WFI instruction, so the state of IDLE mode will have dependency on the state of the RUN mode. To avoid showing a lot of IDLE modes, the following two IDLE states are defined:
  • System IDLE: the IDLE mode entered from Low Speed Run mode. When entering from other RUN modes, the difference is mainly the CPU/BUS frequency.
  • Low Power IDLE: the IDLE mode entered from Low Power RUN mode.
• SUSPEND Mode: CPU power gated, all clocks gated only except 32KHz, analog modules also enter low power state. It provides the lowest power while keeps the system alive, but it would have longer exit time.
• SNVS Mode: All the modules are turned off, only except RTC is active.

There is a single hardware signal (stop_mode) coming into PMU which sets the PMU in either of two "STOP" states. The STOP state is controlled by the PMU_MISC0[STOP_MODE_CONFIG] bit (See PMU Memory Map/Register).
Definition). It is recommended that the blocks be configured for safe powerdown/up through the registers before asserting the stop_mode signal. Blocks not described in the section below are unaffected by stop_mode.

If the stop_mode_config is set to zero, thus in the STOP mode all blocks powered down in minimum power configuration.

If the stop_mode_config is set to one, thus in the STOP mode some of the blocks remain powered and in different states as defined in the table below.

13.4.2 Power management techniques

The device supports the power-management techniques with the features found here.

- Partitioning of the device into voltage, power, clock, and reset domains
- Domain isolation that allows flexible configurations of domains on/off states to form use cases targeting various applications
- Clock tree with selective clock-gating conditions and almost independent clock roots
- Power, reset, and clock control hardware mechanism to manage sleep and wake-up dependencies of power domains
- Software-controllable and hardware-controllable clock gating for functional modules and buses
- Memory retention and state retention capability (Software State Retention for Arm core) for preserving memory contents and device state in low-power modes
- Support for low-power device modes input/output (I/O) pad configuration for minimum power
- Variety of operating modes to optimize device performance and wake-up times
- Thermal monitoring and thermal aware performance management
Many of the low power features are fully or partially software controllable and can be configured for the specific requirements of a target system.

Combining these techniques, the system designer may meet tight requirements of low-power standby and operational modes while maintaining high performance for time-critical tasks.

### 13.4.2.1 Power saving techniques

The table below lists power saving techniques supported by the SoC in their connection to different components of power consumption.

### 13.4.2.2 Thermal-aware power management

The temperature sensor block (TEMPMON) implements a temperature sensor/conversion function. The block features an alarm function that can raise an interrupt signal if the temperature is above a specified threshold.

Software may implement temperature aware DVFS for the Arm domain as well as temperature aware frequency scaling for other system components to ensure that both the frequency and voltage is lowered when the die temperature is above the specified limit.

Software may also implement temperature aware task scheduling to ensure that non-critical tasks are suspended when the die temperature is above the specified limit.

See Temperature Monitor (TEMPMON) for further details on temperature monitor functions and programmability options.
13.4.2.3 Peripheral Power management

13.4.2.3.1 IO power reduction

Software configures IO to low power modes:

- PHYs - make sure that all unused PHYs are placed to lowest power state. Please refer relevant chapter for further information about different PHYs
- Digital IOs - Make sure all unnecessary PU/PD are disabled and IO are switched to either minimal drive strength or to input mode (when applicable)

13.4.2.4 Examples of External Power Supply Interface

This section presents the example of external power supply interfacing to the chip.

The scenario based on integrated PMU system is presented in the following figure. This scenario minimizes BoM and board design complexity.
13.5 ONOFF (Button)

The chip supports the use of a button input signal to request main SoC power state changes (i.e. On or Off) from the PMU.

The ONOFF logic inside of SNVS_LP allows for connecting directly to a PMIC or other voltage regulator device. The logic takes a button input signal and then outputs a pmic_en_b and set_pwr_off_irq signal. PMIC logic also supports the SNVS_LP tamper logic which will allow waking the system up when a tamper event has happened while in the OFF state. The logic has two different modes of operation (Dumb and Smart mode).

The Dumb PMIC mode uses a 2 state state machine, as shown below. The output of the pmic_en_b is generated by the state of the state machine.
The Dumb PMIC Mode uses pmic_en_b to issue a level signal for on and off. Dumb pmic mode has many different configuration options which include (debounce, off to on time, and max time out).

- **Debounce**: The debounce configuration supports 0 msec, 50 msec, 100 msec and 500 msec. The debounce is used to generate the set_pwr_off_irq interrupt. While in the ON state and the button is pressed longer than the debounce time the set_pwr_off_irq is generated.
- **Off to On Time**: The Off to On configuration supports 0 msec, 50 msec, 100 msec, and 500 msec. This configuration supports the time it takes to request power on after the configured button press time has been reached. After the button is pressed longer than the configuration time, the state machine will transition from the OFF to the ON state.
- **Max Timeout**: The max timeout configuration supports 5 secs, 10 secs, 15 secs and disable. This configuration supports the time it takes to request power down after the button has been pressed for the defined time.

The Smart PMIC mode is meant to connect to another PMIC. The pmic_en_b signal issues a pulse instead of a level signal. The only configuration option available for this mode is the Debounce configuration that is used for the set_pwr_off_irq.

### 13.6 WAKEUP Pin

This chip supports the use of a WAKEUP pin (GPIO5_IO00 ALT5) to request main SoC power on to exit SNVS mode. To use it, follow the tips below.
• SNVS must be in Dumb PMIC mode (default, and must for on-chip DCDC)
• Configure IOMUXC_SNVS to select WAKEUP pin ALT5 to mux it to GPIO5_IO00
• Configure GPIO5 ICR to either low level or high level sensitive
• Set GPIO5 IMR bit0 to enable GPIO5_IO00 interrupt
• Enter SNVS mode by SW or ON/OFF button, then on-chip DCDC will be off, and PMIC_ON_REQ pin will also go to low to notify outside
• Assert WAKEUP pin for at least two 32 KHz cycles (active high or low depends on GPIO5 ICR configuration), so that GPIO5 interrupt gets sampled by SNVS module
• SNVS will assert PMIC_ON_REQ pin high and on-chip DCDC begins to ramp on
• SoC power on procedure (except SNVS) begins (ROM boot, …)
Chapter 14
Clock Controller Module (CCM)

**NOTE**

The OCRAM clock cannot be turned off when CM7 Cache is running, on this device. See CCM_CCGR3[CG14] bitfield.

System STOP/WAIT status can be observed on pin. See CCM_STOP/CCM_WAIT in the "Muxing Options" table of the External Signals and Pin Multiplexing chapter, for pin muxing details.

14.2 Overview

The Clock Control Module (CCM) generates and controls clocks to the various modules in the design and manages low power modes. This module uses the available clock sources to generate the clock roots.
The Clock Controller Module controls the following functions:

- Uses the available clock sources to generate clock roots to various parts of the chip:
  - PLL1 also referenced as ARM PLL
  - PLL2 also referenced as System PLL
  - PLL3 also referenced as USB1 PLL
  - PLL4 also referenced as Audio PLL
  - PLL5 also referenced as Video PLL
  - PLL6 also referenced as ENET PLL
  - PLL7 also referenced as USB2 PLL (This PLL is only used by the USB UTM interface through a direct connection.)
- Uses programmable bits to control frequencies of the clock roots.
- Controls the low power mechanism.
- Provides control signals to LPCG for gating clocks.
- Provides handshake with SRC for reset performance.
- Provides handshake with GPC for support of power gating operations.

14.2.1 Features

The CCM includes these distinctive features:

- Provides root clock to SoC modules based on several source clocks.
- Arm core root clock is generated from a dedicated source clock.
- Includes separate dividers to control generation of core and bus root clocks (AXI, AHB, IPG).
- Includes separate dividers and clock source selectors for each serial root clock.
- Optional external clocks to bypass PLL clocks.
- Selects clock signals to output on CCM_CLKO onto the pads for observability.
- Controllable registers are accessible via IP bus.
- Manages the Low Power Modes, namely RUN, WAIT and STOP. The gating of the peripheral clocks is programmable in RUN and WAIT modes.
- Manages frequency scaling procedure for Arm core clock by shifting between PLL sources, without loss of clocks.
- Manages frequency scaling procedure for peripheral root clock by programmable divider. The division is done on the fly without loss of clocks.
- Interface for the following IPs:
  - PLL - Interfaces for each PLL
  - LPCG - Low Power Clock Gating unit
  - SRC - System Reset Controller
  - GPC - General Power Controller
14.2.2 CCM Block Diagram

CCM contains the following sub-blocks:

**Table 14-2. CCM Sub-blocks**

<table>
<thead>
<tr>
<th>CCM_CLK_SRC_DIV Sub-block</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CCM_CLK_IGNITION</td>
<td>Manages the ignition process. This module starts its functionality after CCM comes out of reset. It manages the process that begins with starting the OSC, PLLs and finishes with creation of stable output root clocks after reset.</td>
</tr>
<tr>
<td>CCM_CLK_SWITCHER</td>
<td>Receives the clock outputs of the PLLs, together with the bypass clocks for the PLLs, and generates switcher clock outputs (pll3_sw_clk) for the CCM_CLK_ROOT_GEN sub-module.</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*

14.4 CCM Clock Tree

The following figures (Part 1 and Part 2) show the clock tree configuration and clock roots for CCM.

For detailed sub-block information, see:

i.MX RT1060 Processor Reference Manual, Rev. 2, 12/2019
• Clock Switcher
• Clock Root Generator
• Low Power Clock Gating module (LPCG)
• System Clocks

**NOTE**

The default frequency values (in MHz) for the PLLs and PFDs are shown in the Clock Tree diagram that follows. The PLLs and PFDs control registers may be reprogrammed according to the speed grade of the SoC being used, but should not exceed that maximum setting for that speed grade.
NOTE

In this device, the clock root for FlexIO3 is also flexio2_clk_root, and the bitfield of clock selector/divider is shared for FlexIO2/FlexIO3.

14.5 System Clocks

The table found here shows the CCM output clocks' system-level connectivity.
The gating option in the table can either be CGR bit or clock enable from the block itself. Applicable override bits are also shown.

### 14.6 Functional Description

This section provides a complete functional description of the block.

#### 14.6.1 Clock Generation

**14.6.1.1 External Low Frequency Clock - CKIL**

The chip can use a 32 kHz or 32.768 kHz crystal as the external low-frequency source (XTALOSC). Throughout this chapter, the low-frequency crystal is referred to as the 32 kHz crystal.

This clock source should always be active when the chip is powered on. The 32 kHz entering the CCM are referred to as CKIL. CKIL is synchronized to IPG_CLK and supplied to modules that need it.

**14.6.1.1.1 CKIL synchronizing to IPG_CLK**

CKIL is synchronized to ipg_clk when the system is in functional mode. When the system is in STOP mode (when there is no IPG_CLK) the CKIL synchronizer is bypassed, and raw CKIL is supplied to the system.
14.6.1.2 External High Frequency Clock - CKIH and internal oscillator

The chip uses an internal oscillator to generate the reference clock (OSC). The internal oscillator is connected to the external crystal (XTALOSC) which generates the 24 MHz reference clock.

14.6.1.3 PLL reference clock

There are several PLLs in this chip.

PLL1 - ARM PLL (typical functional frequency )
PLL2 - System PLL (functional frequency 528 MHz)
PLL3 - USB1 PLL (functional frequency 480 MHz)
PLL4 - Audio PLL
PLL5 - Video PLL
PLL6 - ENET PLL
PLL7 - USB2 PLL (functional frequency 480 MHz)

Some of the PLLs are described in the sections below. See CCM Analog Memory Map/Register Definition for register information.

14.6.1.3.1 ARM PLL (PLL1)

This PLL synthesizes a low jitter clock from a 24 MHz reference clock. The clock output frequency for this PLL ranges from 650 MHz to 1.3 GHz. The output frequency is selected by a 7-bit register field CCM_ANALOG_PLL_ARM[DIV_SELECT].

PLL output frequency = \( F_{ref} \times \frac{DIV\_SEL}{2} \)

**NOTE**

The upper frequency range may exceed the maximum frequency supported. Please see the datasheet for more information.

14.6.1.3.2 System PLL (PLL2)

This PLL synthesizes a low jitter clock from the 24 MHz reference clock. The PLL has one output clock, plus 4 PFD outputs. The System PLL supports spread spectrum modulation for use in applications to minimize radiated emissions. The spread spectrum PLL output clock is frequency modulated so that the energy is spread over a wider
bandwidth, thereby reducing peak radiated emissions. Due to this feature support, the associated lock time of this PLL is longer than other PLLs in the SoC that do not support spread spectrum modulation.

Spread spectrum operation is controlled by configuring the CCM_ANALOG_PLL_SYS_SS register. When enabled, the PLL output frequency will decrease by the amount defined in the STEP field, until it reaches the limiting frequency in the STOP field. The frequency will then similarly return to the original nominal frequency. The following equations control the spread-spectrum operation:

$$\text{Spread spectrum range} = \text{Ref} \times \frac{\text{CCM_ANALOG_PLL_SYS_SS[STOP]}}{\text{CCM_ANALOG_PLL_SYS_DENOM[B]}}$$

$$\text{Modulation frequency} = \text{Ref} \times \frac{\text{CCM_ANALOG_PLL_SYS_SS[STEP]}}{2 \times \text{CCM_ANALOG_PLL_SYS_SS[STOP]}}$$

Although this PLL does have a DIV_SELECT register field, it is intended that this PLL will only be run at the default frequency of 528 MHz.

This PLL also supports a Fractional-N synthesizer.

14.6.1.3.3  USB1 PLL (PLL3)

These PLLs synthesize a low jitter clock from the 24 MHz reference clock. USB1 PLL has 4 frequency-programmable PFD (phase fractional divider) outputs.

The output frequency of USB1 PLL is 480 MHz. Even though USB1 PLL has a DIV_SELECT register field, this PLL should always be set to 480 MHz in normal operation.

14.6.1.3.4  Audio PLL (PLL4)

The audio PLL synthesize a low jitter clock from a 24 MHz reference clock. The clock output frequency range for this PLL is from 650 MHz to 1.3 GHz. It has a Fractional-N synthesizer.

There are /1, /2, /4 post dividers for the Audio PLL. The output frequency can be set by programming the fields in the CCM_ANALOG_PLL_AUDIO, and CCM_ANALOG_MISC2 register sets according to the following equation.

$$\text{PLL output frequency} = \text{Ref} * (\text{DIV_SELECT} + \text{NUM/DENOM})$$
14.6.1.3.5 Video PLL (PLL5)

The video PLL synthesize a low jitter clock from a 24 MHz reference clock. The clock output frequency range for this PLL is from 650 MHz to 1.3 GHz. It has a Fractional-N synthesizer.

There are /1, /2, /4, /8, /16 post dividers for the Video PLL. The output frequency can be set by programming the fields in the CCM_ANALOG_PLL_VIDEO, and CCM_ANALOG_MISC2 register sets according to the following equation.

\[ \text{PLL output frequency} = \text{Fref} \times (\text{DIV_SELECT} + \text{NUM/DENOM}) \]

14.6.1.3.6 Ethernet PLL (PLL6)

This PLL synthesizes a low jitter clock from the 24 MHz reference clock.

The reference clocks generated by this PLL are:

- ref_enetpll1 programmable to 25, 50, 100 and 125 MHz by setting CCM_ANALOG_PLL_ENET[DIV_SELECT] bitfield
- ref_enetpll2 fixed at 25 MHz

14.6.1.3.7 USB2 PLL (PLL7)

USB2 PLL is only used by the USB UTM interface through a direct connection.

14.6.1.4 Phase Fractional Dividers (PFD)

There are several PFD outputs from the System PLL and USB1 PLL.

Each PFD output generates a fractional multiplication of the associated PLL’s VCO frequency. Where the output frequency is equal to Fvco*18/N, N can range from 12-35. The PFDs allow for clock frequency changes without forcing the relock of the root PLL. This feature is useful in support of dynamic voltage and frequency scaling (DVFS). See CCM Analog Memory Map/Register Definition.

When the related PLL is powered up from the power down state or made to go through a relock cycle due to PLL regrogramming, it is required that the related PFDx_CLKGATE bit in CCM_ANALOG_PFD_480n or CCM_ANALOG_PFD_528n, be cycled on and off (1 to 0) after PLL lock. The PFDs can be in the clock gated state during PLL relock but must be un-clock gated only after lock is achieved. See the engineering bulletin, Configuration of Phase Fractional Dividers (EB790) at www.nxp.com for procedure details.
14.6.1.5  **CCM internal clock generation**

The clock generation is comprised of two sub-modules:

CCM_CLK_SWITCHER  
CCM_CLK_ROOT_GEN  

14.6.1.5.1  **Clock Switcher**

The Clock Switcher (CCM_CLK_SWITCHER) sub-module receives the PLL output clocks and the PLL bypass clocks.

**Figure 14-4** describes the generation of the three switcher clocks.

The figure also includes the Frequency Switch Control sub-module responsible for frequency change.
14.6.1.5.2 PLL bypass procedure

In addition to PLL bypass options in CCM_ANALOG module, switcher and clk_root_gen sub-modules includes capability for each of the PLL clocks to be bypassed with an external bypass clock.

Figure 14-4. Switcher clock generation
14.6.1.5.3 PLL clock change

In order to modify or stop the clock output of a specific PLL, all the clocks generated from the current PLL must be transitioned to the new PLL whose frequency is not being modified.

For clocks which can't be stopped (core and bus clocks), this should be done via the glitchless mux. Before changing the PLL setting, power it down. Power up the PLL after the change. See Disabling / Enabling PLLs for more information.

14.6.1.5.4 Clock Root Generator

The Clock Root Generator (CCM_CLK_ROOT_GEN) sub-module generates the root clocks to be delivered to LPCG.

The following figures describe clock generation. The frequencies in parentheses are the default typical frequencies.

Figure 14-5. BUS clock generation
NOTE
All 6-bit PODF dividers found in the diagrams above can operate on low frequency.

14.6.1.5.5 Divider change handshake
Modifying the following dividers will start the handshake:
- periph_clk_sel
- arm_podf
- ahb_podf

The dividers listed above are designed with a handshake. For dividers without a handshake design, the following sequence must be performed when updating PODF value:
1. Gate the output clock off before updating PODF value.
2. Gate the output clock on after the PODF value is updated and stable.

To update the PODF value without gating the output clock off will cause unpredictable results such as no clock output.

14.6.1.6 Disabling / Enabling PLLs
PLL disabling and enabling is done via analog module.

Before disabling a PLL using the analog registers, software should first move all the clocks generated from that specific PLL to another source. This alternate source could be another PLL, or a PFD driven by another PLL. Alternatively, software can bypass the PLL and use the PLL reference clock (usually 24 MHz) as the output clock. Bypassing the PLL is done by setting the analog BYPASS bit in the control register for that PLL.

14.6.1.7 Clock Switching Multiplexers
There are a multitude of multiplexers available throughout the clock generation logic that provide alternate clock sources for the system clocks controlled by the CCM. The CCM uses several synchronous glitchless clock multiplexers as well as asynchronous glitchy clock multiplexers.

Synchronous muxes ensure there are no glitches between the transition of two asynchronous clocks and that there will be no pulses that are of a frequency higher than either input clock. For the synchronous multiplexer to work properly, both the current clock and the clock to be selected must remain active during the entire selection process.
There are several glitchless (synchronous) muxes used in the CCM. The table below lists the muxes and the respective control bits.

### Table 14-6. Glitchless Multiplexers

<table>
<thead>
<tr>
<th>Glitchless Mux</th>
<th>Mux Select Bit</th>
<th>Handshake Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>periph_clk_mux</td>
<td>CBCDR[periph_clk_sel]</td>
<td>CDHIPR[periph_clk_sel_busy]</td>
</tr>
<tr>
<td>semc_clk_mux</td>
<td>CBCDR[semc_clk_sel]</td>
<td></td>
</tr>
<tr>
<td>pll3_sw_clk_mux</td>
<td>CCSR[pll3_sw_clk_sel]</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

Any change of the periph_clk_sel sync mux select will involve handshake. Refer to the CDHIPR register for the handshake busy bits.

For critical system bus clocks, changing the clock source can be done in the CCM using the glitchless clock muxes in Figure 14-5. In the figure, the thick bar on the input side indicates the glitchless muxes. Those without the thick bar are regular muxes (not glitchless).

For example, before disabling PLL2, software can switch the AHB_CLK_ROOT away from the PLL2 or one of its PFDs by programming CBCMR[PERIPH_CLK2_SEL] and CBCDR[PERIPH_CLK2_PODF] to provide an appropriate frequency clock, then glitchlessly switch to it by programming CBCDR[PERIPH_CLK_SEL].

Asynchronous multiplexers or glitchy multiplexers, allow the clock to switch immediately after the multiplexer select changed. This immediate switch of two asynchronous clock domains can cause the output clock to glitch. Since both clock sources to the mux are asynchronous, switching the clocks from one source to the other can cause a glitch to be generated, regardless of the input clock source.

The output clocks to the mux are required to be gated before switching the source clock in the CCM clock mux. If the output clocks are not gated, clock glitches can propagate to the logic that follows the clock mux, causing the logic to behave unpredictably.

For serial clocks, software should first disable the module, then gate its clock in the LPCG. Then it should move the mux controlling the source of the clocks to another PLL, and reset the module and its clocks. Only then is it safe to disable the PLL. The mux for the serial clocks is not glitchless.

### 14.6.1.8 Low Power Clock Gating module (LPCG)

The LPCG module receives the root clocks and splits them to clock branches for each module. The clock branches are gated clocks.
The enables for those gates can come from four sources:

1. Clock enable signal from CCM - this signal is generated by configuring of the CGR bits in the CCM. It is based on the low power mode.
2. Clock enable signal from the module - this signal is generated by the module based on internal logic of the module. Not every enable signal from the module is used. For used clock enable signals from the module, CCM will generate an override signal based on a programable bit in CCM (CMEOR).
3. Clock enable signal from Reset controller (SRC) - this signal will enable the clock during the reset procedure. Please see the SRC chapter for details on the clock enable signal during reset procedure.
4. Hard-coded enable from fuse box.

These enable signals are ANDed to generate the enable signal for the gating cell.

The enable signal for the gating cell is synchronized with the clock it needs to gate in order to prevent glitches on the gated clock.

Notifications are generated for CCM to indicate when clock roots should be opened and closed. All notifications that correspond to the same clock root will be ORed to generate one notification signal to CCM for clock root gating.

The following figure describes the clock split inside the LPCG module. It describes the case of two modules; one module is without an enable signal and one is shown with an enable signal. SRC enable signals and sync flip flops are omitted from this figure.
14.6.2 DVFS support

When performing DVFS, the frequency shift procedure for the Arm core clock domain can be performed by software.

CPU PLL frequency and CCM ARM clock divider is controlled by CCM and CPU power domain supply voltage value is controlled by CCM_ANALOG module.

NOTE
The frequency should be shifted down first and then voltage value reduced, and vice-versa, when shifting the frequency up.

NOTE
CCM_ANALOG will not control the voltage value in Bypass mode
14.6.3 Power modes

The chip supports 3 low power modes: RUN mode, WAIT mode, STOP mode.

14.6.3.1 RUN mode

This is the normal/functional operating mode. In this mode, the CPU runs in its normal operational mode. Clocks to the modules can be gated by configuring the corresponding CCGRx bits.

14.6.3.2 WAIT mode

In this mode the CPU clock is gated. All other clocks are functional and can be gated by programming their CGR bits when all Arm cores are in WFI, and L2 cache and SCU are idle.

14.6.3.2.1 Entering WAIT mode

If the CLPCR[LPM] bit is set by software to WAIT mode, when CPU executes the next wait for interrupt (WFI) instruction, WAIT mode sequence will start.

As part of the WFI routine, alternative interrupt controller in GPC should be updated; the CPU platform interrupt controller will be disabled first by software and will be not functional, due to clock gating. Interrupts during WAIT mode are monitored by alternative interrupt controller.

After execution of the WFI routine, the CPU platform will assert idle signals for each component of the platform and CCM will gate clock to the platform.

The next actions can be programmed during WAIT mode:

1. CCM request will be issued if the handshake is not bypassed by programing the CLPCR register. If the corresponding bits are set, the request signal will not be issued to the corresponding module and CCM will not wait for its acknowledge in the process of entering low power mode. After CCM receives all the acknowledge signals needed, then it will enter WAIT mode.
2. Close the clocks to the modules which were defined to be shut at WAIT mode in the CCGR bits.
3. Observability to indicate WAIT mode.

Any enabled interrupt assertion will start the exit from WAIT mode.
14.6.3.2.2 Exiting WAIT mode

As soon as enabled interrupt is asserted, CPU supply will be restored if CPU SRPG was applied and clocks are enabled to CPU and other modules.

14.6.3.3 STOP mode

In this mode all system clocks are stopped, along with the CPU, system buses and all PLLs. Power gating can be applied for Arm platform. External supply voltage can be reduced to decrease leakage.

14.6.3.3.1 Entering STOP mode

Procedure entering STOP mode is the same, as entering WAIT mode until the moment of disabling clocks to modules. (LPM bit should be configured to STOP mode.)

After clocks to modules are gated, the following actions will be taken:

- PLLs are disabled
- CCM_PMIC_STBY_REQ asserted, if vstby bit is set
- osc_en signal is negated
- osc_pwrdn is asserted, if sbyos bit is set

Counter will be triggered after CCM_PMIC_STBY_REQ assertion to allow to external regulator or PMIC to decrease voltage until valid voltage range. On counter completion, stop_mode signal will be asserted, that will trigger disabling analog elements in anatop. CCM's low power state machine will remain in state STOP_GPC until STOP mode is exited.

14.6.3.3.2 Exiting STOP mode

As soon as an enabled interrupt is asserted, the CCM will begin the process of exiting STOP mode.

The following will take place:

1. If vstby bit was set, deassert PMIC_STBY_REQ to notify power management IC to change voltage from standby voltage to functional voltage.
2. If sbyos was set, and CCM closed either external oscillator or on board oscillator, then CCM will start oscillator by asserting ref_en_b signal and deasserting cosc_pwrdown signal respectively.
3. After the number of cycles of CKILs defined in stby_count bits, wait until PMIC functional voltage is ready. This is the notification from power management IC that the voltage is ready at its functional value. Only then will CCM continue the steps.
4. Start osc. If oscillator was started, wait until oscnt has finished its counting to make sure that oscillator is ready.
5. Start PLLs. Only the PLLs that were configured to be on prior to the entrance to STOP mode will be started.
6. CCM will request GPC to restore Arm power by GPC_PUP_REQ. If power was removed from the Arm platform, GPC will notify CCM by asserting signal GPC_PUP_ACK that power to Arm is back on, and its safe to exit from STOP mode. Only then will the CCM progress to the next step.
7. After assertion of notification from src that the resets for the power gated modules has been finished, (src_power_gating_reset_done is set) negate the low power request signals to all modules and enable all module clocks including Arm clocks and CKIL sync, and return to run mode. (Clocks whose CCGR bits are not to be opened in RUN mode will not be opened; they will continued to be gated.)

After the system is in run mode, the ccm_ipg_stop and system_in_stop_mode signals negate.

14.7 CCM Memory Map/Register Definition

NOTE
The register reset values for CCM change depending on the boot configuration. See Clocks at boot time for more information.

### 14.7.8 CCM Serial Clock Multiplexer Register 2 (CCM_CSCMR2)

The figure below represents the CCM Serial Clock Multiplexer Register 2 (CSCMR2). The CSCMR2 register contains bits to control the multiplexers that generate the serial clocks. The table below provides its field descriptions.

**NOTE**

Any change on the above multiplexer will have to be done while the module that its clock is affected is not functional and...
the clock is gated. If the change will be done during operation of the module, then it is not guaranteed that the modules operation will not be harmed.

14.7.9  CCM Serial Clock Divider Register 1 (CCM_CSCDR1)

The figure below represents the CCM Serial Clock Divider Register 1 (CSCDR1). The CSCDR1 register contains bits to control the clock generation sub-module dividers. The table below provides its field descriptions.

**NOTE**

Any change on the above dividers will have to be done while the module that its clock is affected is not functional and the affected clock is gated. If the change will be done during operation of the module, then it is not guaranteed that the modules operation will not be harmed.

14.7.15  CCM Divider Handshake In-Process Register (CCM_CDHIPR)

The figure below represents the CCM Divider Handshake In-Process Register (CDHIPR). The CDHIPR register contains read-only bits that indicate that CCM is in the process of updating dividers or muxes that might need handshake with modules.

Address: 400F_C000h base + 48h offset = 400F_C048h

---

The diagram shows the layout of the CDHIPR register with the following fields:

- **R** (Read-Only): The register contains read-only bits.
- **ARM_PODF_BUSY**: Indicates if the ARM PODF is busy.
- **Reset**: The default state of the register when reset.

The diagram illustrates the bit positions and their default values upon reset.

14.7.17 CCM Interrupt Status Register (CCM_CISR)

The figure below represents the CCM Interrupt Status Register (CISR). This is a write one to clear register. After an interrupt is generated, software should write one to clear it. The table below provides its field descriptions.

**NOTE**

CCM interrupt request 1 can be masked by CCM interrupt request 1 mask bit. CCM interrupt request 2 can be masked by CCM interrupt request 2 mask bit.

14.7.19  CCM Clock Output Source Register (CCM_CCOSR)

The figure below represents the CCM Clock Output Source Register (CCOSR). The CCOSR register contains bits to control the clock that will be generated on the output ipp_do_clko1. The table below provides its field descriptions.

### 14.7.21 CCM Clock Gating Register 0 (CCM_CCGR0)

**CG(i) bits CCGR 0-6**

These bits are used to turn on/off the clock to each module independently. The following table details the possible clock activity conditions for each module.

<table>
<thead>
<tr>
<th>CGR value</th>
<th>Clock Activity Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>Clock is off during all modes. Stop enter hardware handshake is disabled.</td>
</tr>
<tr>
<td>01</td>
<td>Clock is on in run mode, but off in WAIT and STOP modes</td>
</tr>
<tr>
<td>10</td>
<td>Not applicable (Reserved).</td>
</tr>
<tr>
<td>11</td>
<td>Clock is on during all modes, except STOP mode.</td>
</tr>
</tbody>
</table>

Module should be stopped, before set its bits to "0"; clocks to the module will be stopped immediately.

The tables above show the register mappings for the different CGRs. The clock connectivity table should be used to match the "CCM output affected" to the actual clocks going into the modules.
The figure below represents the CCM Clock Gating Register 0 (CCM_CCGR0). The clock gating Registers define the clock gating for power reduction of each clock (CG(i) bits). There are 7 CGR registers. The number of registers required is according to the number of peripherals in the system.

14.7.24 CCM Clock Gating Register 3 (CCM_CCGR3)

The figure below represents the CCM Clock Gating Register 3 (CCM_CCGR3). The clock gating Registers define the clock gating for power reduction of each clock (CG(i) bits). There are 8 CGR registers. The number of registers required is determined by the number of peripherals in the system.

**NOTE**

The OCRAM clock cannot be turned off when CM7 Cache is running. For details, refer to CCM_CCGR3[CG14] bitfield.

14.7.29 CCM Module Enable Override Register (CCM_CMEOR)

The follow figure represents the CCM Module Enable Override Register (CMEOR). The CMEOR register contains bits to override the clock enable signal from the module. This bit will be applicable only for modules whose clock enable signals are used. The following table provides its field descriptions.

Address: 400F_C000h base + 88h offset = 400F_C088h

This section describes the registers for the analog PLLs. The registers which have the same description are grouped within {}. The register offsets for the various PLLs are:

- **ARM PLL**: \{0h000, 0h004, 0h008, 0h00C\}.
- **USB1 PLL**: \{0h010, 0h014, 0h018, 0h01C\}, \{0h0F0, 0h0F4, 0h0F8, 0h0FC\}.
- **System PLL**: \{0h030, 0h034, 0h038, 0h03C\}, 0h040, 0h050, 0h060, \{0h100, 0h104, 0h108, 0h10C\}.
- **Audio / Video PLL**: \{0h070, 0h074, 0h078, 0h07C\}, 0h080, 0h090, \{0h0A0, 0h0A4, 0h0A8, 0h0AC\}, 0h0B0, 0h0C0

**25 CLKGATE_CTRL**

This bit allows disabling the clock gate (always ungated) for the xtal 24MHz clock that clocks the digital logic in the analog block.

**NOTE:** Do not change the field during a low power event. This is not a field that the user would normally need to modify.

**NOTE:** Not related to CCM. See Crystal Oscillator (XTALOSC)

0  **ALLOW_AUTO_GATE** — Allow the logic to automatically gate the clock when the XTAL is powered down.

1  **NO_AUTO_GATE** — Prevent the logic from ever gating off the clock.

**24–17 -**

This field is reserved.

Always set to zero.

**16 OSC_XTALOK_EN**

This bit enables the detector that signals when the 24MHz crystal oscillator is stable.

**NOTE:** Not related to CCM. See Crystal Oscillator (XTALOSC)

**15 OSC_XTALOK**

Status bit that signals that the output of the 24-MHz crystal oscillator is stable. Generated from a timer and active detection of the actual frequency.

**NOTE:** Not related to CCM. See Crystal Oscillator (XTALOSC)

**14–13 OSC_I**

This field determines the bias current in the 24MHz oscillator. The aim is to start up with the highest bias current, which can be decreased after startup if it is determined to be acceptable.

**NOTE:** Not related to CCM. See Crystal Oscillator (XTALOSC)

00  **NOMINAL** — Nominal

01  **MINUS_12.5_PERCENT** — Decrease current by 12.5%

10  **MINUS_25_PERCENT** — Decrease current by 25.0%

11  **MINUS_37.5_PERCENT** — Decrease current by 37.5%

**12 DISCON_HIGH_SNVS**

This bit controls a switch from VDD_HIGH_IN to VDD_SNVS_IN.

0  Turn on the switch

1  Turn off the switch

**11–10 STOP_MODE_CONFIG**

Configure the analog behavior in stop mode.

00  All analog except RTC powered down on stop mode assertion.

01  Beside RTC, analog bandgap, 1p1 and 2p5 regulators are also on.

10  Beside RTC, 1p1 and 2p5 regulators are also on, low-power bandgap is selected so that the normal analog bandgap together with the rest analog is powered down.

11  Beside RTC, low-power bandgap is selected and the rest analog is powered down.

</table>
| 7     | REFTOP_VBGUP Status bit that signals the analog bandgap voltage is up and stable. 1 - Stable.  
**NOTE:** Not related to CCM. See Power Management Unit (PMU) |
| 6–4   | REFTOP_VBGADJ  
**NOTE:** Not related to CCM. See Power Management Unit (PMU)  
000 Nominal VBG  
001 VBG+0.78%  
010 VBG+1.56%  
011 VBG+2.34%  
100 VBG-0.78%  
101 VBG-1.56%  
110 VBG-2.34%  
111 VBG-3.12% |
| 3     | REFTOP_SELFBIASOFF Control bit to disable the self-bias circuit in the analog bandgap. The self-bias circuit is used by the bandgap during startup. This bit should be set after the bandgap has stabilized and is necessary for best noise performance of analog blocks using the outputs of the bandgap.  
**NOTE:** Value should be returned to zero before removing vddhigh_in or asserting bit 0 of this register (REFTOP_PWD) to assure proper restart of the circuit.  
**NOTE:** Not related to CCM. See Power Management Unit (PMU)  
0 Uses coarse bias currents for startup  
1 Uses bandgap-based bias currents for best performance |
| 2–1   | This field is reserved. |
| 0     | REFTOP_PWD Control bit to power-down the analog bandgap reference circuitry.  
**NOTE:** A note of caution, the bandgap is necessary for correct operation of most of the LDO, PLL, and other analog functions on the die.  
**NOTE:** Not related to CCM. See Power Management Unit (PMU) |
14.8.18 Miscellaneous Register 1 (CCM_ANALOG_MISC1n)

This register defines the control and status bits for miscellaneous analog blocks. The LVDS1 and LVDS2 controls below control the behavior of the anaclk1/1b LVDS IO.

Address: 400D_8000h base + 160h offset + (4d × i), where i=0d to 3d

15.2 Overview

This block comprises both the 24 MHz and 32 kHz implementation of a biased amplifier that when combined with a suitable external quartz crystal and external load capacitors, implements an oscillator.

The block includes means to:

- Accept an external clock source.
- Detect if the crystal frequency is close to 24 MHz or 32 kHz.
- Reduce the operating current via software after the oscillator has started (24 MHz specific feature)
- Supply another ~32 kHz clock source based off an independent internal oscillator if there is no oscillation sensed on the RTC_XTAL bumps (contacts) (32 kHz specific feature)
feature). The internal oscillator will provide clocks to the same on-chip modules as the external 32 kHz oscillator.

- Automatically switch to the external oscillation source when sensed on the RTC_XTAL bumps (contacts) (32 kHz specific feature).

15.3 External Signals

The table found here describes the external signals of XTALOSC:

15.4 Crystal Oscillator 24 MHz

15.4.1 Oscillator Configuration (24 MHz)

The basic block diagram of the 24 MHz module configured as a crystal oscillator is shown below.
This integrated biased amplifier can be used to create different frequency oscillators with different external component selection. However, care should be taken as many of the serial IO modules depend on the fixed frequency of 24 MHz. Please consult the sections of the document pertaining to the USB, ENET interfaces, for example. After a healthy oscillation is established, then the bias current of the oscillator can generally be reduced to save power. This is accomplished through the XTALOSC24M_MISC0[OSC_I] bits, defined in the MISC0 register later in this chapter. Restore the XTALOSC24M_MISC0[OSC_I] bits before going into a power mode where the XTALOSC24 is powered down or oscillator startup may become an issue. The power down of the XTALOSC24 module is controlled by the CCM. See this section of the manual for more details.

### 15.4.2 Bypass Configuration (24 MHz)

If it is desired to drive the chip with an external clock source, then the 24 MHz oscillator could be driven in one of three configurations using a nominal 1.1V source.

1. A single ended external clock source can be used to overdrive the output of the amplifier (XTALO). Since the oscillation sensing amplifier is differential, the
XTALI pin should be externally floating and capacitively loaded. The combination of the internal biasing resistor and the external capacitor will filter the signal applied to the XTALO pin and develop a rough reference for the sensing amplifier to compare to.

2. A single ended external clock source can be used to drive XTALI. In this configuration, XTALO should be left externally floating.

3. A differential external clock source can be used to drive both XTALI and XTALO.

Generally, configuration 2 is anticipated to be the most used configuration, but all three configurations may be utilized.

### 15.4.3 RC Oscillator (24 MHz)

A lower-power RC oscillator module is available on-chip as a possible alternative to the 24 MHz crystal oscillator after a successful power-up sequence.

The 24 MHz RC oscillator is a self-tuning circuit that will output the programmed frequency value by using the RTC clock as it’s reference. This oscillator is intended for normal operation and not fast boot.

While the power consumption of this RC oscillator is much lower than the 24 MHz crystal oscillator, one limitation of this RC oscillator module is that its clock frequency is not as accurate. Therefore, care should be observed when using this oscillator as the reference for the on-chip PLLs as their output clock frequency will be lower/higher than when using the 24 MHz crystal oscillator clock.

### 15.4.4 Crystal Frequency Detection(24 MHz)

A submodule exists that gives a fairly crude (relative to the accuracy of a crystal) estimation of whether the clock frequency is correct.

This function may be enabled by setting the XTALOSC24M_MISC0[OSC_XTALOK_EN] bit. It is disabled at system reset. When the oscillator is stable and the correct frequency is detected, the XTALOSC24M_MISC0[OSC_XTALOK] bit will be set. Note that the correct frequency will be observed before the oscillator fully blooms (the oscillation waveform build-up is completed).

### 15.5 Crystal Oscillator 32 kHz
15.5.1 Oscillator Configuration (32 kHz)

The basic block diagram of the 32 kHz module configured as a crystal oscillator is shown below.

![Oscillator Configuration (32 kHz) Diagram]

This integrated biased amplifier can be used to create different frequency oscillators with different external component selection. Generally, RTC oscillators are either implemented with 32 kHz or 32.768 kHz crystals. Please consult the Security Reference Manual for appropriate frequency selection and configuration. Care must be taken to limit external leakage as this may debias the amplifier and degrade the gain.

The internal oscillator is automatically multiplexed in the clocking system when the system detects a loss of clock. The internal oscillator will provide clocks to the same on-chip modules as the external 32 kHz oscillator. The internal oscillator is not precise relative to a crystal. While it will provide a clock to the system, it generally will not be precise enough for long term time keeping. The internal oscillator is anticipated to be useful for quicker startup times and tampering prevention, but should not be used as the exclusive source for the 32 kHz clocks. An external 32 kHz clock source must be used for production systems.
15.5.2 Bypass Configuration (32 kHz)

If it is desired to drive the chip with an external clock source, then the 32 kHz oscillator could be driven in one of three configurations using a nominal 1.1V source.

1. A single ended external clock source can be used to overdrive the output of the amplifier (RTC_XTALO). Since the oscillation sensing amplifier is differential, the RTC_XTALI pin should be externally floating and capacitively loaded. The combination of the internal biasing resistor and the external capacitor will filter the signal applied to the RTC_XTALO pin and develop a rough reference for the sensing amplifier to compare to.

2. A single ended external clock source can be used to drive RTC_XTALI. In this configuration, RTC_XTALO should be left externally floating.

3. A differential external clock source can be used to drive both RTC_XTALI and RTC_XTALO.

Generally, configuration 2 is anticipated to be the most used configuration, but all three configurations may be utilized.

15.6 XTAŁOSC 24MHz Memory Map/Register Definition

#### 25 CLKGATE_CTRL

This bit allows disabling the clock gate (always ungated) for the xtal 24MHz clock that clocks the digital logic in the analog block.

**NOTE:** Do not change the field during a low power event. This is not a field that the user would normally need to modify.

- **0 ALLOW_AUTO_GATE** — Allow the logic to automatically gate the clock when the XTAL is powered down.
- **1 NO_AUTO_GATE** — Prevent the logic from ever gating off the clock.

#### 24–17

This field is reserved. Always set to zero.

#### 16 OSC_XTALOK_EN

This bit enables the detector that signals when the 24MHz crystal oscillator is stable.

#### 15 OSC_XTALOK

Status bit that signals that the output of the 24-MHz crystal oscillator is stable. Generated from a timer and active detection of the actual frequency.

#### 14–13 OSC_I

This field determines the bias current in the 24MHz oscillator. The aim is to start up with the highest bias current, which can be decreased after startup if it is determined to be acceptable.

- **00 NOMINAL** — Nominal
- **01 MINUS_12_5_PERCENT** — Decrease current by 12.5%
- **10 MINUS_25_PERCENT** — Decrease current by 25.0%
- **11 MINUS_37_5_PERCENT** — Decrease current by 37.5%

#### 12 DISCON_HIGH_SNV S

This bit controls a switch from VDD_HIGH_IN to VDD_SNVS_IN.

- **0** Turn on the switch
- **1** Turn off the switch

#### 11–10 STOP_MODE_CONFIG

Configure the analog behavior in stop mode.

**NOTE:** Not related to oscillator.

- **00** All analog except rtc powered down on stop mode assertion. XtalOsc=on, RCOsc=off;
- **01** Certain analog functions such as certain regulators left up. XtalOsc=on, RCOsc=off;
- **10** XtalOsc=off, RCOsc=on, Old BG=on, New BG=off.
- **11** XtalOsc=off, RCOsc=on, Old BG=off, New BG=on.

#### 9–8

This field is reserved. Reserved

#### 7 REFTOP_VBGUP

Status bit that signals the analog bandgap voltage is up and stable. 1 - Stable.

**NOTE:** Not related to oscillator.

#### 6–4 REFTOP_VBGADJ

**NOTE:** Not related to oscillator.

- **000** Nominal VBG

3 REFTOP_SELFBIASOFF

Control bit to disable the self-bias circuit in the analog bandgap. The self-bias circuit is used by the bandgap during startup. This bit should be set after the bandgap has stabilized and is necessary for best noise performance of analog blocks using the outputs of the bandgap.

**NOTE:** Value should be returned to zero before removing vddhigh_in or asserting bit 0 of this register (REFTOP_PWD) to assure proper restart of the circuit.

**NOTE:** Not related to oscillator.

0 Uses coarse bias currents for startup
1 Uses bandgap-based bias currents for best performance.

2–1 This field is reserved.

0 REFTOP_PWD

Control bit to power-down the analog bandgap reference circuitry.

**NOTE:** A note of caution, the bandgap is necessary for correct operation of most of the LDO, pll, and other analog functions on the die.

**NOTE:** Not related to oscillator.
## 15.6.2 XTAL OSC (LP) Control Register

  - REG1_ENABLE_BO
16.2 Overview

The power management unit (PMU) is designed to simplify the external power interface. The power system can be split into the input power sources and their characteristics, the integrated power transforming and controlling elements, and the final load interconnection and requirements.

A typical power system uses the PMU is depicted in the following diagram.
Using four LDO regulators, the number of external supplies is greatly reduced. Not counting the backup coin and USB inputs, the number of external supplies is reduced to two. Missing from this external supply total is the number of necessary external supplies to power the desired memory interface; that number varies depending on the type of external memory selected. Other supplies may also be necessary to supply the voltage to the different I/O power segments if their I/O voltages have to be different from what is provided above.

### 16.3 Analog LDO Regulators

There are two analog regulators described here.
**16.3.1 LDO 1P1**

The LDO_1P1 module on the chip implements a programmable linear-regulator function from a higher analog supply voltage (2.8 V–3.3 V) to produce a nominal 1.1 V output voltage.

The output of the regulator can be programmed in 25 mV steps from 0.8 V to 1.4 V. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitance, though the actual capacitance required should be determined by the application. A programmable brownout detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded, so the necessary steps can be taken.

Current limiting can be enabled by setting the PMU_REG_1P1[ENABLE_ILIMIT] bit to allow for in-rush current requirements during startup if needed. Active pulldown can also be enabled by setting the PMU_REG_1P1[ENABLE_PULLDOWN] bit for systems requiring this feature.

**16.3.2 LDO 2P5**

The LDO_2P5 module on the chip implements a programmable linear-regulator function from a higher analog supply voltage (2.8V-3.3V) to produce a nominal 2.5V output voltage.

The output of the regulator can be programmed in 25mV steps from 2.0V to 2.75V. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitance, though the actual capacitance required should be determined by the application. A programmable brown-out detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded to take the necessary steps.

Current-limiting can be enabled by setting the REG_PMU_2P5[ENABLE_ILIMIT] bit to allow for in-rush current requirements during start-up if needed. Active-pulldown can also be enabled by setting the REG_PMU_2P5[ENABLE_PULLDOWN] bit for systems requiring this feature.

**16.3.3 Low Power Operation**

The 1.1 V and 2.5 V LDO includes an alternate, self-biased, low-precision, weak regulator which can be enabled for applications needing to keep the 1.1 V and 2.5 V output voltage alive during low-power modes where the main regulator and its associated global bandgap reference module are disabled.
The output of this weak regulator is not programmable and is a function of its input power supply as well as load current. The low-power mode is enabled by setting high the PMU_REG_1P1[ENABLE_WEAK_LINREG] and PMU_REG_2P5[ENABLE_WEAK_LINREG] bit of the regulator. It is recommended that the following sequence be followed to enable this mode:

1. Throttle down the 1.1 V / 2.5 V attached load to its low-power maintain state.
2. Disable the main 1.1 V / 2.5 V regulator driver by clearing the PMU_REG_1P1[ENABLE_LINREG] / PMU_REG_2P5[ENABLE_LINREG] bit.
3. Enable the weak 1.1 V / 2.5 V regulator by setting the PMU_REG_1P1[ENABLE_WEAK_LINREG] / PMU_REG_2P5[ENABLE_WEAK_LINREG] bit.

To go back to full-power operation, reverse the steps outlined above. Note that the external decoupling cap is supporting the power supply between steps 2 and 3. Therefore step 3 should happen appropriately in time relative to the discharge of the supporting capacitor.

### 16.4 USB LDO Regulator

The USB_LDO module on the chip implements a programmable linear-regulator function from the USB VBUS voltages (typically 5 V) to produce a nominal 3.0 V output voltage.

The output of the regulator can be programmed in 25 mV steps, from 2.625V to 3.4 V. The regulator has been designed to be stable with a minimum external low-ESR decoupling capacitor of 4.7 µF, though the actual capacitance required should be determined by the application. A programmable brownout detector is included in the regulator which can be used by the system to determine when the load capability of the regulator is being exceeded, so the necessary steps can be taken. This regulator has a built-in power mux which allows the user to choose to run the regulator from either VBUS supply when both are present. If only one of the VBUS voltages is present, then the regulator automatically selects this supply. Current limit is also included to help the system meet in-rush current targets.

Upon attachment of VBUS, this regulator starts up in a low-power, self-preservation mode to prevent over-voltage conditions on the chip. It is expected that the user transition to full regulation by enabling the regulator and disabling the in-rush current limits via its control registers. Upon VBUS removal, it is further expected that the regulator controls are returned to their reset state.
16.5 SNVS Regulator

The SNVS regulator takes the SNVS_IN supply and generates the SNVS_CAP supply, which powers the real time clock and SNVS blocks.

The SNVS_LDO is a non-programmable linear-regulator function, producing a nominal 1.1V output voltage.

16.6 PMU Memory Map/Register Definition

The register definitions that affect the behavior of the digital LDO regulators follow.

NOTE
Some of the registers are collections of bits that affect multiple components on the chip. Those that are not pertinent to this chapter have comments in the related register bitfields.

If a full description is desired, please consult the full register programming reference in the related block.

**25**

**CLKGATE_CTRL**

This bit allows disabling the clock gate (always ungated) for the xtal 24MHz clock that clocks the digital logic in the analog block.

*NOTE:* Do not change the field during a low power event. This is not a field that the user would normally need to modify.

*NOTE:* Not related to PMU.

0  **ALLOW_AUTO_GATE** — Allow the logic to automatically gate the clock when the XTAL is powered down.

1  **NO_AUTO_GATE** — Prevent the logic from ever gating off the clock.

| 24–17 | This field is reserved.  
|       | Always set to zero. |

| 16    | This bit enables the detector that signals when the 24MHz crystal oscillator is stable.  
|       | *NOTE:* Not related to PMU, Clocking content |

| 15    | Status bit that signals that the output of the 24-MHz crystal oscillator is stable. Generated from a timer and active detection of the actual frequency.  
|       | *NOTE:* Not related to PMU, clocking content. |

| 14–13 | This field determines the bias current in the 24MHz oscillator. The aim is to start up with the highest bias current, which can be decreased after startup if it is determined to be acceptable.  
|       | *NOTE:* Not related to PMU. |

00  **NOMINAL** — Nominal

01  **MINUS_12.5_PERCENT** — Decrease current by 12.5%

10  **MINUS_25_PERCENT** — Decrease current by 25.0%

11  **MINUS_37.5_PERCENT** — Decrease current by 37.5%

| 12    | This bit controls a switch from VDD_HIGH_IN to VDD_SNVS_IN.  
|       | 0  Turn on the switch  
|       | 1  Turn off the switch |

| 11–10 | Configure the analog behavior in stop mode.  
|       | 00  **SUSPEND (DSM)** — All analog except rtc powered down on stop mode assertion.  
|       | 01  **STANDBY** — Analog regulators are ON.  
|       | 10  **STOP (lower power)** — Analog regulators are ON.  
|       | 11  **STOP (very lower power)** — Analog regulators are OFF. |

| 9–8   | This field is reserved.  
|       | Reserved |

| 7     | Status bit that signals the analog bandgap voltage is up and stable. 1 - Stable. |

17.2 Overview

The General Power Control (GPC) block includes the sub-blocks listed here.

- CPU Power Gating Control (PGC)

Each sub-block has its own IP registers.

GPC determines wake-up IRQ for exiting WAIT/STOP mode (with or without CPU power gating).
17.3 Clocks

The table found here describes the clock sources for GPC.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

17.4 Power Gating Control (PGC)

Power Gating (PGC) is applied to the Arm CPU and FlexRAM optionally in STOP low power mode, after all essential CPU registers data are saved by Arm dormant procedure.
If any of the unmasked interrupts appears, CPU is powered up and clock restore request (exit from STOP mode) is sent to CCM.

**PGC power down sequence:**

- CCM sends power down request when the chip is about to enter stop mode. The user should define which modules will be powered down (CTRL registers of corresponding PGC module, bit 0).

**PGC power up sequence:**

- One of the power up irq is asserted.
- Power up request is asserted in GPC and in CCM.
- The Power Gated modules are powered up, according to PGC settings of appropriate module.

The Power Gated modules require reset after powering up. The next figure describes GPC-SRC handshake procedure for reset after power gating.
17.4.1 Overview

The Power Gating Controller (PGC) is a power management component that controls the power-down and power-up sequencing of individual subsystems.

The sequence timing is programmable using the PGC control registers. Figure 17-3 shows PGC as part of the SoC’s overall power management scheme.
17.4.1.1 Features

Key features of the PGC include:

- Provides the ability to switch off power to a target subsystem.
- Generates power-up and power-down control sequences.
- Provides programmable registers to adjust the timing of the power control signals.

17.5 GPC Interrupt Controller (INTC)

The INTC (Interrupt Controller) detects an interrupt and generates the wakeup signal. It supports up to 160 interrupts.

17.5.1 Interrupt Controller features

The features of the GPC INTC are listed below.

Features:

- Supports up to 160 interrupts
- Provides an option to mask/unmask each interrupt
- Detects interrupts and generates the wake up signal
- 32-bits IP bus interface
- All registers are byte-accessible
17.6  GPC Memory Map/Register Definition

Detailed descriptions of each register can be found below.

Writes to GPC registers only takes effect in supervisor mode.

17.7  PGC Memory Map/Register Definition

The PGC registers can be accessed only in supervisor mode.
Attempts to access registers when not in supervisor mode or attempts to access an unimplemented address location might trigger a bus transfer error. In this case, software should take appropriate action (such as ignore the error, log the error, or initiate a soft reset).

All PGC registers are byte-accessible.

**NOTE**

PGC MEGA is used to control the power gate of PDRAM1 domain. PGC CPU is used to control the power gate of PDM7 domain (CM7 CPU). FlexRAM PDRAM0 domain is further controlled by GPC_CNTR[PDRAM0_PGE] bit.

18.2 Introduction

This module is a synchronous buck mode DCDC converter with a single output.

18.3 Features

The DCDC module includes the following features:

- Buck mode, a single output
- PSWITCH pin to control DCDC to enable or bypass DCDC
- Continuous conduction mode (CCM) and discontinuous conduction mode (DCM) operation
- Power-save mode operation
- Over current protection
• Over voltage protection
• Low voltage detection
• Internal oscillator to support the case when the crystal oscillator is not present as in the block diagram

18.4 Block diagram

Figure 18-1. DCDC block diagram

18.5 Functional description

The DCDC converter is a synchronous step down converter with a single output. In run mode, it can operate in the continuous conduction mode or discontinuous conduction mode, depending on the level of the load current. The load current level is about 50mA in a typical case, but it depends on the exact value of inductance, input voltage level and output target. If DCM mode is enabled, the DCDC can switch to DCM mode automatically if the current of the inductance goes to zero. The current does not need to be monitored to switch modes. Discontinuous conduction mode must be enabled by the register configuration.
The DCDC can also be configured to operate in power-save mode when the load current is less than 50 mA. During the power-save mode, the converter operates with reduced switching frequency in PFM mode and with a minimum quiescent current to maintain high efficiency.

DCM and CCM both work in run mode, in which the DCDC regulates the output continuously.

PFM is Pulse Frequency Modulation. In PFM, which is also named Pulse Mode, the DCDC is idle until the output drops to the low threshold. The DCDC then starts to charge the output to the high threshold. After it reaches the high threshold, the DCDC is idle again.

The DCDC also includes the following three protection functions:
- **Over current protection.** In run mode, DCDC will shut down when detecting abnormal large current in the P-type power switch. In power save mode, DCDC will stop charging inductor when detecting large current in the P-type power switch. The threshold is also different in run mode and in power save mode: the former is 1 A–2 A, and the latter is 200 mA–250 mA.
- **Over voltage protection.** DCDC will shut down when detecting the output voltage is too high.
- **Low voltage detection.** DCDC will shut down when detecting the input voltage is too low.

Another function of DCDC is that it can detect the peak current in the P-channel switch. When the peak current exceeds the threshold, DCDC will give an alert signal, and the threshold can be configured. By this way, DCDC can roughly detect the current loading.

## 18.6 Application information

### 18.6.1 Turn on DCDC

The below conditions must be met to enable the DCDC:
- Power snvs_1p0 and clk32k in snvs_1p0 are available
- DCDC_IN powered up
- After DCDC_IN powered up, delay about 1ms reset time to enable DCDC
- PSWITCH and PMIC_ON_REQ are both high to enable DCDC

The sequence is:
1. Power snvs1p0 and clk32k
2. PMIC_ON_REQ = 1
3. DCDC_IN powered up
4. Delay 1ms reset time
5. PSWITCH = 1
6. DCDC is now enabled

OR:
1. Power snvs_1p0 and clk32k
2. DCDC_IN powered up
3. Delay 1ms reset time
4. PSWITCH = 1
5. PMIC_ON_REQ = 1
6. DCDC is now enabled

Only if when PSWITCH and PMIC_ON_REQ are both high, DCDC can be enabled, PMIC_ON_REQ can be before or after DCDC_IN, just to assure delay about 1ms reset time to enable DCDC after DCDC_IN power up,

NOTE
For safety purpose, over-voltage detector needs to be enabled, i.e. PWD_HIGH_VOLT_DET=1'b0.

18.6.2 Target Voltage Adjustment

DISABLE_STEP=0x0

set TRG

NOTE
If setting disable_step=0, the overshoot will be low when changing the target, but the settling time is longer. If setting disable_step=1, the settling time is shorter, but the overshoot might be higher. The following settings can speed up the settling time: pwd_cmp_offset=0x0; loopctrl_en_rcscale=0x4.

18.6.3 Continuous Conduction Mode

pwd_zcd=0x1
pwd_cmp_offset=0x0
loopctrl_en_rcscale=0x3
18.6.4  Discontinuous Conduction Mode

pwd_zcd=0x0
pwd_cmp_offset=0x0
loopctrl_en_rcscale=0x4
DCM_SET_CTRL=1'b1

NOTE
Because discontinuous conduction mode can increase the efficiency of DCDC in case of low current loading, it is always recommended.

18.6.5  Power Saving Mode

Before entering this mode, set the target value of run mode the same as power saving mode, because DCDC will switch back to run mode if it detects the current loading is larger than about 50 mA (the threshold can be configured).

PMIC_STBY_REQ=0x1

18.7  Memory Map and register definition

This section includes the DCDC module memory map and detailed descriptions of all registers.

### 18.7.1.2.4 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 31 STS_DC_OK     | DCDC Output OK  
This is the status bit indicates if the DCDC output voltage is stable. The lock time depends on the loading and the DCDC mode.  
0b - DCDC is settling  
1b - DCDC already settled |
| 30 __             | Reserved   |
| 29 XTAL_24M_OK   | 24M XTAL OK  
This bit determines if the DCDC uses the internal ring oscillator or the xtal 24M.  
0b - DCDC uses internal ring OSC  
1b - DCDC uses xtal 24M |
| 28 CURRENT_ALERT_RESET | Reset Current Alert Signal |

Table continues on the next page...
### Field | Function
--- | ---
This bit is the reset signal of current detector, if current loading is larger than the threshold of the current detector which is set by CUR_SNS_THRSH, the current detector will give out an alert signal, CURRENT_ALERT_RESET can reset the alert signal.  
- 0b - Current Alert Signal not reset  
- 1b - Current Alert Signal reset
27 | XTA Lopez_DISAB I LE  
Disable xtalok detection circuit  
This is a debug bit which should not be changed in real case. This bit disables and bypasses the clock 24 MHz reference clock detector.  
- 0b - Enable xtalok detection circuit  
- 1b - Disable xtalok detection circuit and always outputs OK signal "1"  
26 | PWD_CMP_OFFSET  
Power down output range comparator  
Output range comparator monitors the output voltage of DCDC. When the DCDC output voltage is out of range, this comparator will speed up DCDC control loop in an attempt to bring the DCDC output voltage back in range.  
PWD_CMP_OFFSET must be set to 0 (output range comparator on) if LOOPCTRL_EN_RCSCALE is to be used to speed up the transient response.  
- 0b - Output range comparator powered up  
- 1b - Output range comparator powered down
25 | Reserved
24 | Reserved
23 | Reserved
22 | Reserved
21 | LP_HIGH_HYS  
Low Power High Hysteric Value  
Adjust hysteretic value in low power from 12.5mV to 25mV  
- 0b - Adjust hysteretic value in low power to 12.5mV  
- 1b - Adjust hysteretic value in low power to 25mV
20 | LP_OVERLOAD_FREQ_SEL  
Low Power Overload Frequency Select  
The period of counting the charging times in power save mode  
- 0b - eight 32k cycle  
- 1b - sixteen 32k cycle
19-18 | LP_OVERLOAD_THRSH  
Low Power Overload Threshold  
The threshold of the counting number of charging times during the period that lp_overload_freq_sel sets in power save mode.  
- 00b - 32  
- 01b - 64  
- 10b - 16  
- 11b - 8
17 | PWD_HIGH_VOLT_DET  
Power Down High Voltage Detection  
Power down overvoltage detection comparator  
- 0b - Overvoltage detection comparator is enabled

Table continues on the next page...
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 16 1b - Overvoltage detection comparator is disabled | Low Power Overload Sense Enable
Enable the overload detection in power save mode, if current is larger than the overloading threshold (typical value is 50 mA), DCDC will switch to the run mode automatically
0b - Overload Detection in power save mode disabled
1b - Overload Detection in power save mode enabled |
| 15-12 Reserved |                                                                           |
| 11 0b - Low voltage detection comparator is enabled | Power Down Battery Detection Comparator
Set to "1" to power down the low voltage detection comparator
0b - Low voltage detection comparator is enabled
1b - Low voltage detection comparator is disabled |
| 10-9 Overcurrent Trigger Adjust | The threshold of over current detection in run mode and power save mode:
00b - In Run Mode, 1 A. In Power Save Mode, 0.25 A
01b - In Run Mode, 2 A. In Power Save Mode, 0.25 A
10b - In Run Mode, 1 A. In Power Save Mode, 0.2 A
11b - In Run Mode, 2 A. In Power Save Mode, 0.2 A |
| 8 0b - Overcurrent detection comparator is enabled | Power down overcurrent detection comparator
0b - Overcurrent detection comparator is enabled
1b - Overcurrent detection comparator is disabled |
| 7-5 Current Sense (detector) Threshold | Set the threshold of current detector, if the peak current of the inductor exceeds the threshold, the current detector will assert.
000b - 150 mA
001b - 250 mA
010b - 350 mA
011b - 450 mA
100b - 550 mA
101b - 650 mA |
| 4 0b - Current Detector powered up | Power down signal of the current detector.
Power down the control signal of the current detector.
0b - Current Detector powered up
1b - Current Detector powered down |
| 3 0b - Internal oscillator powered up | Power down internal osc
Only set this bit when 24 MHz crystal osc is available
0b - Internal oscillator powered up
1b - Internal oscillator powered down |
| 2 0b - DCDC uses internal ring oscillator | Select Clock
Select 24 MHz Crystal clock for DCDC, when DISABLE_AUTO_CLK_SWITCH is set.
If DISABLE_AUTO_CLK_SWITCH is set to 0 and 24M xtal is OK, the clock source will switch from internal ring OSC to 24M xtal automatically. If DISABLE_AUTO_CLK_SWITCH is set to 1, SEL_CLK will determine which clock source the DCDC uses: if SEL_CLK=0, DCDC will use internal ring OSC, if SEL_CLK=1, DCDC will use 24M xtal.
0b - DCDC uses internal ring oscillator

19.2 Overview

The temperature sensor module implements a temperature sensor/conversion function based on a temperature-dependent voltage to time conversion.

The module features alarm functions that can raise independent interrupt signals if the temperature is above two high-temperature thresholds and below a low temperature threshold. These temperature thresholds are programmable and designated as low, high and panic temperature. The panic threshold is a special programmable threshold in that if the temperature increases above this value and the temperature-panic-reset interrupt is enabled in the System Reset Controller, the hardware will assume that software no longer has control over the thermal situation and will initiate a reset of the chip.
In order to avoid false panic temperature initiated resets, the panic alarm will not fire until the temperature panic condition has been met for four consecutive conversion cycles. A self-repeating mode can also be programmed which executes a temperature sensing operation based on a programmed delay.

Since the high and low temperature thresholds are programmable, they form a sliding temperature bracket that can be tailored to the application’s needs. For example, at start-up software can set the low temperature threshold to the minimum temperature code and the high temperature threshold to a maximum operating temperature for the system.

The system can then use this module to monitor the on-die temperature and take appropriate actions such as throttling back the core frequency when a high temperature interrupt is set. After the high temperature interrupt is set then the system can program the low temperature threshold to a desired cool down temperature. The system would then switch to monitoring the low temperature alarm and wait for its interrupt to be set. With this scheme, after the low temperature interrupt is set then software could be assured that the temperature has cooled down to a safe level and the process could be repeated.

The high-level implementation of the temperature sensor is shown in the figure below.

**Figure 19-1. High Level Temp Sensor System Diagram**

As shown in the figure above, the temperature sensor uses and assumes that the bandgap reference, 480MHz PLL and 32KHz RTC modules are properly programmed and fully settled for correct operation.
19.3 Software Usage Guidelines

During normal system operation software can use the temperature sensor counter output (TEMP_CNT) in conjunction with the fused temperature calibration data to determine the on-die operational temperature or to set an over-temperature interrupt alarm to within a couple of °C.

Based on calibration, two sets of temperature and counter values will be available via fuses on the device. These data points will correspond to the points \((N_1, T_1)\) and \((N_2, T_2)\) in the curve below.

![Figure 19-2. Temperature Measurement Cycle](image)

After a temperature measurement cycle, software should use the calibration points in conjunction with the temperature code value in the TEMPMON_TEMPSENSE0[TEMP_CNT] bitfield to calculate the temperature for the device using the following equation:

\[
T_{\text{meas}} = T_2 - (N_{\text{meas}} - N_2) \times \left( \frac{(T_2 - T_1)}{(N_1 - N_2)} \right)
\]

Likewise, to determine the alarm counter value to be written in the TEMPMON_TEMPSENSE0 register for a temperature based interrupt, the above equation can be solved for the \(N_{\text{meas}}\) value that should be used based on the desired temperature trigger.

The temperature calibration point fuse values are available in the OCOTP_ANA1 register. The temperature calibration values are fused individually for each part in the product testing process. The fields of this register are described in the following table.
Table 19-2. OCOTP_ANA1 Temperature Sensor Calibration Data

<table>
<thead>
<tr>
<th>Bit Range</th>
<th>Bit Mask</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>[31:20]</td>
<td>FFF0_0000h</td>
<td>ROOM_COUNT</td>
<td>Value of TEMPMON_TEMPSENSE0[TEMP_VALUE] after a measurement cycle at room temperature (25.0 °C).</td>
</tr>
<tr>
<td>[19:8]</td>
<td>000F_FF00h</td>
<td>HOT_COUNT</td>
<td>Value of TEMPMON_TEMPSENSE0[TEMP_VALUE] after a measurement cycle at the hot temperature, i.e. HOT_TEMP.</td>
</tr>
<tr>
<td>[7:0]</td>
<td>0000_00FFh</td>
<td>HOT_TEMP</td>
<td>The hot temperature test point. Each LSB equals 1 °C.</td>
</tr>
</tbody>
</table>

The points on the calibration curve are as follows.

- \((N_1, T_1) = (ROOM_COUNT, 25.0)\)
- \((N_2, T_2) = (HOT_COUNT, HOT_TEMP)\)
- \((N_{\text{meas}}, T_{\text{meas}}) = (\text{TEMP_CNT}, T_{\text{meas}})\)

Substituting the fields from OCOTP_ANA1 into the earlier equation results in the following:

\[
T_{\text{meas}} = \text{HOT_TEMP} - (N_{\text{meas}} - \text{HOT_COUNT}) \times \left(\frac{\text{HOT_TEMP} - 25.0}{\text{ROOM_COUNT} - \text{HOT_COUNT}}\right)
\]

20.2 SNVS introduction

SNVS is a companion module to the DCP module.

SNVS incorporates both security and non-security functionality. The SNVS non-security functionality is described in this document, but the SNVS security functionality is described only in the Security Reference Manual.

SNVS non-security functions:
- Realtime Counter (RTC) - a software accessible realtime counter
  - RTC can be set to the value in the SRTC
Periodic Interrupt - a hardware-generated interrupt that occurs periodically at software-specified frequency

General Purpose Register - a set of registers used to hold 128 bits of data specified by software
  - If the SNVS_LP power input is connected to an uninterrupted power supply, e.g. a coin cell battery, the GPR value is maintained when main SoC is powered off

Chip power-on/power-off - If the SNVS_LP power input is connected to an uninterrupted power supply and the Power On button input signal is connected to a power button external to the chip, logic within SNVS_LP can be used to wake the chip from a power down.

### 20.2.1 SNVS feature list

The following table summarizes the features of SNVS:

</table>
| Wakeup from power off    | • Input signal from off chip requests SNVS_LP to power on the main SoC (Assuming that the SNVS_LP power input is connected to an uninterrupted power supply (see SNVS power domains).)  
• Hardware debounces the input signal using software-specified signal bounce characteristics | LP Wake-Up Interrupt Enable   |

20.2.2 SNVS functional description

SNVS implements several non-security features that involve software interaction:
- reading or writing the Realtime Counter (RTC) (This is a non-privileged operation.) - software can also instruct SNVS to load the current SRTC value into the RTC
- reading or writing the General Purpose Register (GPR) (Note that there may be a significant delay when reading or writing registers in the LP section if the LP clock is different from the HP clock.)

The following sections describe in more detail the operation of SNVS.

20.3 SNVS Structure

SNVS is organized as two major sub-modules:
- Low-Power Section of SNVS (SNVS_LP)

The SNVS_LP section provides hardware that enables secure storage and protection of sensitive data. The SNVS module is designed to safely hold security-related data such as cryptographic key, time counter, monotonic counter, and general purpose security information.

The SNVS_LP block implements the following functional units:
- Control and Status Registers
- General Purpose Registers

When the LP section is powered by a backup battery the state of these registers is maintained even when the main chip power is off. (see SNVS power domains)

- High-Power Section of SNVS (SNVS_HP)

The SNVS_HP section contains all SNVS status and configuration registers. It implements all features that enable system communication and provisioning of the SNVS_LP section.
The SNVS_HP provides an interface between SNVS_LP and the rest of the system.

The SNVS_HP block implements the following functional units:
- IP Bus Interface
- SNVS_LP Interface
- Zeroizable Master Key Programming Mechanism
- Real Time Counter with Alarm Control and Status Registers
- Control and status registers

SNVS_HP is in the chip's power supply domain and thus receives power along with the rest of the chip.

The following figure illustrates the structure of SNVS.
20.3.1 SNVS power domains

In some versions of SNVS (including this version), the LP (Low Power) section is implemented in an independent power domain from the HP (High Power) section, and most other logic on the chip. Throughout the SNVS documentation whenever mention is made of "always-on" logic, this assumes a version of SNVS that implements an independent power domain for the LP section, and that the power for this section is supplied by an uninterrupted power supply. The purpose for the independent power domain is so that data can be retained and certain logic can remain functional even when the main chip logic is powered down. But this is possible only if the LP domain remains powered via an uninterrupted power supply when the main chip power domain is powered off. Usually this uninterrupted power supply would be a coin-cell battery, with possibly some power management logic to power the LP section from main power (and perhaps recharge the coin cell battery) when main power is on, and switch to coin-cell power when the main power is off. In versions of SNVS with an independent LP power domain the LP section can be electrically isolated from the rest of the chip logic to ensure that its logic does not get corrupted when the main chip is powered down. If the battery runs down or is removed, an LP POR will occur when the LP section next powers up. Note that some OEMs may choose to connect LP power to HP/main chip power and dispense with a coin cell battery. In that case the SNVS will operate the same as an SNVS without an independent LP power domain. No state will be retained in the LP section when the chip is powered down, and an LP POR will occur whenever there is an HP POR.

20.3.2 SNVS clock sources

The SNVS has the following clock sources:

- System peripheral clock input. This clock is used by the SNVS's internal logic, for example, the Security State Machine. This clock can be gated outside of the module when the SNVS indicates that it is not in use.
- HP RTC clock. This clock is used by SNVS_HP real-time counter. This clock does not need to be synchronous with other clocks.

20.4 Runtime Procedures

SNVS implements a number of features that are intended to be accessed by software at runtime (as opposed to accessed at boot time). These features include:

- Real Time Clock (see SNVS_HP Real Time Counter)
- Secure Real Time Clock (see SNVS_LP Secure Real Time Counter (SRTC))
• General Purpose Register (see Using the General-Purpose Register)
• Monotonic Counter (see Using the Monotonic Counter (MC))

Procedures for using these features are described in the following sections.

20.4.1 Using SNVS Timer Facilities

SNVS incorporates timer facilities that can optionally generate an interrupt at a specified time. As described in the following sections, SNVS_HP incorporates a Real Time Counter that is available for general use, and SNVS_LP incorporates a Secure Real Time Counter intended for security applications.

20.4.1.1 SNVS_HP Real Time Counter

SNVS_HP implements a real time counter that can be read or written by any application; it has no privileged software access restrictions. When the chip is powered down the RTC is not active and it is reset at chip POR. The RTC can be used to generate a functional interrupt request either at a specific time, or at a specific frequency, or both. To generate an interrupt request at a specific time HPTA_EN is set to 0, the desired time is written to HPTA_MS and HPTA_LS and then HPTA_EN is set to 1. HPTA_EN, HPTA_MS and HPTA_LS can be written by any software that has access to SNVS registers; there are no privileged access restrictions. The counter can be synchronized to the SNVS_LP SRTC by writing to the HP_TS bit of SNVS_HP Control Register. This is particularly useful if the SNVS_LP is powered from an uninterrupted power source (e.g. a coin cell battery) because the RTC can then be set from a chip-internal time source.

20.4.1.2 RTC/SRTC control bits setting

All SNVS registers are programmed from the register bus, consequently any software-initiated changes are synchronized with the IP clock. Several registers can also change synchronously with the RTC/SRTC clock after they are programmed. To avoid IP clock and RTC/SRTC clock synchronization issues, the following values can be changed only when the corresponding function is disabled.

<table>

</tr>
</tbody>
</table>

Use the following steps to program synchronized values:

1. Check the enable bit value. If set, clear it.
2. Verify that the enable bit is cleared. There are two reasons to verify the enable bit's setting:
   - Enable bit clearing does not happen immediately; it takes three IP clock cycles and two RTC/SRTC clock cycles to change the enable bit's value.
   - If the enable bit is locked for programming, it cannot be cleared.
3. Program the desired value.
4. Set the enable bit; it takes three IP clock cycles and two RTC/SRTC clock cycles for the bit to set.

**NOTE**

Incrementing the value programmed into RTC/SRTC registers by two compensates for the two RTC/SRTC clock cycle delay that is required to enable the counter.

### 20.4.1.3 Reading RTC and SRTC values

Software should follow the following procedure to ensure that it has read correct data from the RTC (HPRTCNR and HPRTCLR) and SRTC (LPSRTCMR and LPSRTCLR) registers:
• Read the most-significant half and the least-significant half of the RTC/SRTC and then read both halves again. If the values read are the same both times, the value is correct.
• If the two consecutive pairs of reads yield different results, perform two more reads.

The worst case scenario may require three sessions of two consecutive pairs of reads. There are several reasons that the values may be incorrectly read initially:
• Synchronization issues between the RTC/SRTC clock and the system clock
• Since the counter continues to increment, there may be a carry from the least-significant 32-bits to the most-significant bits in between reading the two halves of the counter

20.4.2 Using Other SNVS Registers

The sections below describe how to use the General Purpose Register.Monotonic Counter. The sections below describe how to use the General Purpose Register and the Monotonic Counter.

20.4.2.1 Using the General-Purpose Register

SNVS implements a 128-bit general-purpose register allows software to store a small amount of data. To maintain backward compatibility with versions of SNVS that implement only a 32-bit general purpose register, the most-significant word of the general purpose register is aliased to the legacy address. The data in the GPR will be retained during system power-down mode as long as the SNVS_LP remains powered by an uninterrupted power source (e.g. coin cell battery).

20.5 Reset and Initialization of SNVS

SNVS is implemented in two sections (HP and LP) that both must be initialized by software following POR. If the SNVS_LP is powered by an uninterrupted power source that is separate from main SoC power, then SNVS can operate in either of two modes, depending upon whether the main SoC power is on or off. During main SoC power-down SNVS_HP is powered-down, but SNVS_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode SNVS_LP keeps its registers' values and monitors the SNVS_LP tamper detection inputs, but the LP registers cannot be read or written. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power.
Both LP and HP registers can be read and written (locks and privilege modes permitting). Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational.

Since the HP and LP sections reside in different power domains, the POR for the two sections can occur at different times. If the SNVS_LP section remains powered by an uninterrupted power source when the main SoC power is off, SNVS_LP is initialized rarely, typically once when the device is first powered on and again whenever the battery is replaced. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational. The SNVS_HP section is powered from the main SoC power, so it must be initialized whenever the device is powered on. If the SNVS_LP section is powered from the main SoC power rather than from an uninterrupted power source, the SNVS_LP section must also be initialized at SoC POR.

Initializing the LP section The following steps should be completed to properly initialize the SNVS LP section (required only on LP POR, i.e. when the battery is replaced):

1. Program the Power Glitch Detector and clear the power glitch record in the LP status register
2. If the SRTC will be used, set the Secure Real Time Clock
3. If the ZMK will be used, provision the ZMK
4. If the Monotonic Counter will be used, burn an additional Monotonic Counter Era bit in the fuse bank and reset the Monotonic Counter

Initializing the HP section The following steps should be completed to properly initialize the SNVS HP section (following successful completion of secure boot):

1. Perform normal or secure boot to put the SNVS into a functional state (Non-secure, Trusted, Secure)
2. At SNVS_LP POR a power glitch violation will be asserted. Therefore at the first HP POR following an LP POR software should write the proper initialization value (41736166h) into the LPPGDR and clear the power glitch record in the LP status register. See Power glitch detector (PGD) for more details.
3. Transition SSM from trusted state to secure state (if not already done by HAB).
4. Enable security violations and interrupts in HPSVCR and HPSICR registers
5. Program SNVS general functions/configurations
6. Select Master Key (OTPMK, ZMK or XOR of the two. Default is OTPMK.)
7. Set lock bits. The ms bit of the SNVS_HP lock register should be set before starting any functional operation. Setting this bit prevents further changes to the Master Key selection.
20.5.1 Initialization Checklists

SNVS is implemented in two sections (HP and LP) that both must be initialized by software following POR. If the SNVS_LP is powered by an uninterrupted power source that is separate from main SoC power, then SNVS can operate in either of two modes, depending upon whether the main SoC power is on or off. During main SoC power-down SNVS_HP is powered-down, but SNVS_LP is powered from the backup power supply and is electrically isolated from the rest of the chip. In this mode SNVS_LP keeps its registers' values and monitors the SNVS_LP tamper detection inputs, but the LP registers cannot be read or written. During main SoC power-up the isolation of SNVS_LP is disabled and both SNVS_HP and SNVS_LP are powered from the main SoC power. Both LP and HP registers can be read and written (locks and privilege modes permitting). Signals between the SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational.

Since the HP and LP sections reside in different power domains, the POR for the two sections can occur at different times. If the SNVS_LP section remains powered by an uninterrupted power source when the main SoC power is off, SNVS_LP is initialized rarely, typically once when the device is first powered on and again whenever the battery is replaced. During main SoC power-up the isolation of SNVS_LP is disabled and both
SNVS_HP and SNVS_LP are powered from the main SoC power. Signals between the
SNVS_HP and SNVS_LP sections are enabled and all SNVS functions are operational.
The SNVS_HP section is powered from the main SoC power, so it must be initialized
whenever the device is powered on. If the SNVS_LP section is powered from the main
SoC power rather than from an uninterrupted power source, the SNVS_LP section must
also be initialized at SoC POR.

20.6 SNVS register descriptions

This section contains detailed register descriptions for the SNVS registers. Each
description includes a standard register diagram and register table. The register table
provides detailed descriptions of the register bit and field functions, in bit order.

SNVS registers consist of two types:

- Privileged read/write accessible
- Non-privileged read/write accessible

Privileged read/write accessible registers can only be accessed for read/write by
privileged software. Unauthorized write accesses are ignored, and unauthorized read
accesses return zero. Non-privileged software can access privileged access registers when
the non-privileged software access enable bit is set in the SNVS_HP Command Register.

- Non-Secure
- Trusted
- Secure

Non-privileged read/write accessible registers are read/write accessible by any software.
The LP register values are set only on LP POR and are unaffected by System (HP) POR.
The HP registers are set only on System POR and are unaffected by LP POR.

The following table shows the SNVS main memory map.

NOTE
For more information on security-related bitfields, see the
Security Reference Manual for this device.

20.6.4.4 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

Table continues on the next page...
### Field | Function
--- | ---
27 | Button interrupt mask. This bit is used to mask the ipi_snvs_btn_int_b (button) interrupt request.  
   | 0: Interrupt disabled  
   | 1: Interrupt enabled
26-24 | Button Configuration. This field is used to configure which feature of the button (BTN) input signal constitutes “active”.  
   | 000: Button signal is active high  
   | 001: Button signal is active low  
   | 010: Button signal is active on the falling edge  
   | 011: Button signal is active on the rising edge  
   | 100: Button signal is active on any edge  
   | All other patterns are reserved.
23-17 | Reserved.
16 | Reserved
15 | Reserved.
14-10 | HP Calibration Value  
   | Defines signed calibration value for the HP Real Time Counter. This field can be programmed only when RTC Calibration is disabled (HPCALB_EN is not set). This is a 5-bit 2's complement value, hence the allowable calibration values are in the range from -16 to +15 counts per 32768 ticks of the counter.  
   | 00000b - +0 counts per each 32768 ticks of the counter  
   | 00001b - +1 counts per each 32768 ticks of the counter  
   | 00010b - +2 counts per each 32768 ticks of the counter  
   | 01111b - +15 counts per each 32768 ticks of the counter  
   | 10000b - -16 counts per each 32768 ticks of the counter  
   | 10001b - -15 counts per each 32768 ticks of the counter  
   | 11110b - -2 counts per each 32768 ticks of the counter  
   | 11111b - -1 counts per each 32768 ticks of the counter
9 | Reserved.
8 | HP Real Time Counter Calibration Enabled  
   | Indicates that the time calibration mechanism is enabled.  
   | 0b - HP Timer calibration disabled  
   | 1b - HP Timer calibration enabled
7-4 | Periodic Interrupt Frequency  
   | Defines frequency of the periodic interrupt. The interrupt is generated when a zero-to-one or one-to-zero transition occurs on the selected bit of the HP Real Time Counter and Real Time Counter and Periodic Interrupt are both enabled (RTC_EN and PI_EN are set). It is recommended to program this field when Periodic Interrupt is disabled (PI_EN is not set). The possible frequencies are:  
   | 0000b - bit 0 of the HPRTCLR is selected as a source of the periodic interrupt  
   | 0001b - bit 1 of the HPRTCLR is selected as a source of the periodic interrupt  
   | 0010b - bit 2 of the HPRTCLR is selected as a source of the periodic interrupt

*Table continues on the next page...*
### Field | Function
--- | ---
0011b | bit 3 of the HPRTCLR is selected as a source of the periodic interrupt
0100b | bit 4 of the HPRTCLR is selected as a source of the periodic interrupt
0101b | bit 5 of the HPRTCLR is selected as a source of the periodic interrupt
0110b | bit 6 of the HPRTCLR is selected as a source of the periodic interrupt
0111b | bit 7 of the HPRTCLR is selected as a source of the periodic interrupt
1000b | bit 8 of the HPRTCLR is selected as a source of the periodic interrupt
1001b | bit 9 of the HPRTCLR is selected as a source of the periodic interrupt
1010b | bit 10 of the HPRTCLR is selected as a source of the periodic interrupt
1011b | bit 11 of the HPRTCLR is selected as a source of the periodic interrupt
1100b | bit 12 of the HPRTCLR is selected as a source of the periodic interrupt
1101b | bit 13 of the HPRTCLR is selected as a source of the periodic interrupt
1110b | bit 14 of the HPRTCLR is selected as a source of the periodic interrupt
1111b | bit 15 of the HPRTCLR is selected as a source of the periodic interrupt

20.6.13  SNVS_LP Secure Monotonic Counter MSB Register (LPSMCMR)

20.6.13.1  Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>LPSMCMR</td>
<td>5Ch</td>
</tr>
</tbody>
</table>

20.6.13.2  Function

The SNVS_LP Secure Monotonic Counter MSB Register contains the monotonic counter era bits and the most-significant 16 bits of the monotonic counter. The monotonic counter is incremented by one if there is a write command to the LPSMCMR or LPSMCLR register. This is a non-privileged read-only register.

<td>MC_ERA_BITS</td>
<td>These bits are inputs to the module and typically connect to fuses. When the Monotonic Counter is in use (i.e. enabled and valid and powered by an uninterrupted power source, e.g. a coin cell battery), and the boot software detects that the Monotonic Counter most-significant 16 Bits and Monotonic Counter LSB Register have been reset (MC_ENV=0), the boot software can take action to ensure that the value in the...</td>
</tr>
</tbody>
</table>

Table continues on the next page...
### Monotonic Counter remains monotonic (i.e. never decreasing).

The action is to blow an additional MC_ERA_BITS fuse. Since the MC_ERA_BITS field forms the most-significant field of the monotonic counter, blowing an additional fuse guarantees that the new monotonic counter value is higher than any previous value. Typically this would be necessary only when the coin cell battery is changed. Since the Monotonic Counter is reset on an LP Software Reset, an excessive number of MC_ERA_BITS fuses may be consumed if LP Software Reset is used repeatedly.

20.6.15.2 Function

The SNVS_LP General Purpose Register is a 128-bit read/write register located in SNVS_LP, which can be used by any application for retaining data during an SoC power-down mode. This is a privileged read/write register. The full GPR register is accessed as 4 32-bit registers located in successive word addresses starting at offset 100h. For backward compatibility with earlier versions of SNVS, LPGPR0..LPGPR3 are aliased at the earlier offset of 90h and LPGPR0 is aliased at its original offset of 68h. The GPR will be automatically zeroized when a tamper event occurs, unless GPR zeroization is disabled via the GPR_Z_DIS bit in the LP Control Register.

21.2 SRC Overview

The System Reset Controller (SRC) controls the reset and boot operation of the SoC.

It is responsible for the generation of all reset signals and boot decoding.

The reset controller determines the source and the type of reset, such as POR, COLD, and performs the necessary reset qualification and stretching sequences. Based on the type of reset, the reset logic generates the reset sequence for the entire IC. Whenever the chip is powered on, the reset is issued through SRC_ONOFF signal and the entire chip is reset.

21.2.1 Features

The SRC includes the following features.
• Receives and handles the resets from all the reset sources
• Resets the appropriate domains based upon the resets sources and the nature of the reset
• Latches the SRC_BOOT_MODE pins and common configuration signals from the internal fuse

21.3 External Signals

The following table describes the external signals of SRC.

#### 21.5 Top-level resets, power-up sequence and external supply integration

Information found here defines chip resets, power-up sequence, and external supply integration.

#### 21.5.1 Reset and Power-up Flow

The chip presumes the following reset and power-up flow:
Top-level resets, power-up sequence and external supply integration

**Figure 21-1. Chip reset scheme under PMU control**

Note: PMIC_ON_REQ acts as an active high-signal
1 or high Z = ON
0 = OFF
Figure 21-2. Chip reset scheme under external PMIC control

PMIC_ON_REQ acts as power-on alarm:
0->1 = power-on by alarm

PMIC_STBY_REQ enters and exits PMIC standby
0->1 = enter standby
1-> 0 = wake-up from standby
Top-level resets, power-up sequence and external supply integration

#### 21.6 Power-On Reset and power sequencing

This module generates an internal POR_B signal that is logically AND'ed with any externally applied SRC_POR_B signal. The internal POR_B signal will be held low until all of the following conditions are met:

- 4ms after the external power supply VDDHIGH_IN is valid
- 1ms after the VDD_SOC_IN supply is valid

The 4ms and 1ms delays are derived from counting the 32 kHz RTC clock cycles; the accuracy depends on the accuracy of the RTC. When the RTC crystal is either absent or in the process of powering up, an internal ring oscillator will be the source of RTC, which is not as accurate as the crystal.

##### 21.6.1 External POR using SRC_POR_B

If the external SRC_POR_B signal is used to control the processor POR, SRC_POR_B must remain low (asserted) until the VDD_SOC supplies are stable.
21.6.2 Internal POR

If the external SRC_POR_B signal is not used (always held high or left unconnected), the processor defaults to the internal POR function (PMU controls generation of the POR based on the power supplies).

21.7 Functional Description

21.7.1 Reset Control

This section details the reset control of this device.

21.7.1.1 Reset inputs and outputs

The reset control logic receives reset requests from all potential reset sources. All the immediate sources of reset are directly passed to the reset stretching block, whereas the resets requiring qualification are passed on to the reset qualification logic before they are sent to the reset stretching block.

All reset inputs and outputs are described in the following figure:
The reset types and modules they affect are shown in Table 21-5. As there is no chip POR, the POR_B is used to reset the entire chip including test logic and JTAG modules.

**NOTE**

All resets are expected to be active low except jtag_sw_rst.

### Table 21-5. SRC reset functionality

<table>
<thead>
<tr>
<th>SoC Modules</th>
<th>POR</th>
<th>COLD</th>
</tr>
</thead>
<tbody>
<tr>
<td>System modules (PLLs, fuses, etc)</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>Functional modules</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>Arm</td>
<td>yes</td>
<td>yes</td>
</tr>
<tr>
<td>IOMUXC</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>Arm debug</td>
<td>yes</td>
<td>no</td>
</tr>
<tr>
<td>SJC</td>
<td>yes</td>
<td>no</td>
</tr>
</tbody>
</table>
The reset priorities are POR (strongest) and COLD (weakest). If a stronger reset is asserted during the sequence of a weaker reset, then the weaker sequence will be overridden, and the stronger reset sequence will commence. There is no priority within a reset type (POR, etc). If a reset is asserted during the reset sequence of the same type, the reset sequence will be interrupted and restarted.

The following lists the functionality of each of these reset outputs:

- system_early_rst_b - Resets the system modules that need to start first as CCM, OCOTP_CTRL, FUSEBOX, etc.
- system_rst_b - Resets functional modules
- arm_rst_b - Resets Arm module (on regular system reset)
- arm_por_rst_b - Resets Arm POR input
- arm_dbg_rst_b - Reset debug logic of Arm
- test_logic_rst_b - Reset test logic (IOMUXC, DAP)
- sjc_por_rst_b - Reset to SJC

**NOTE**

It is assumed that each reset source will deassert after its assertion, either due to reset generated to the system from SRC, or by negation of the reset source (if it came from an external source to the chip). In the latter case, the reset source is assumed to be held for at least 2 XTALI clocks so it can be sampled by SRC.

### 21.7.1.2 Reset Handling

#### 21.7.1.2.1 POR (SRC_POR_B)

SRC_POR_B is an external reset signal. When the chip is powered up, the reset signal is passed through the POR_B pin indicating power-up sequence. The SRC resets the entire chip including the JTAG (SJC) module. All SRC registers will be reset during the POR sequence.

As soon as SRC_POR_B occurs, all resets are asserted and the entire chip is reset by SRC. The SRC_POR_B is stretched for 2 XTALI cycles and the stretching sequence takes place after 2 XTALI clocks of POR_B pin deassertion.

The sjc_por_rst_b signal is deasserted together with SRC_POR_B signal. The output is also deasserted after the stretching of SRC_POR_B has deasserted.

After the above resets deassert, system_early_rst_b reset is deasserted after 2 XTALI clocks. The system_early_rst_b is used for the CCM and PLL-IPs to start generating PLL clock outputs and the system root clocks.
When the system root clocks are ready, the CCM will assert system_clk_ready signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation.

SRC then enables OCOTP_CTRL and fusebox clocks, so that fuses can be loaded to OCOTP_CTRL.

- SRC will prepare the boot information
- After 8 ipg cycles, resets to all modules will be de-asserted
- After 8 ipg cycles, system clocks will be enabled (en_system_clk).

21.7.1.2.2 COLD RESET

The sequence is similar to SRC_POR_B except the memory repair operation is not performed.

After the reset source deasserts, system_early_rst_b reset is deasserted after at least 2 XTALI clocks. The system_early_rst_b is used for the CCM and PLL-IPs to start generating PLL clock outputs and the system root clocks.

After the system root clocks are ready, the CCM will assert system_clk_ready signal. This signal is generated during the start sequence in the CCM and it involves the preparation of the PLLs to generate clock roots for functional operation. See CCM for more information.

After system_clk_ready arrives at the SRC, it will enable OCOTP_CTRL and fusebox clocks, so that fuses can be loaded to OCOTP_CTRL. OCOTP_CTRL will notify with iim_ready_flag when the fusebox loading finishes.

- SRC will prepare the boot information
- After 8 ipg cycles resets to all modules will be deasserted
- After 8 ipg cycles, system clocks will be enabled (en_system_clk).

21.7.2 Parallel Reset Requests

SRC will follow the following rules in the case of parallel reset requests:

1. The order of strength of resets is POR - strongest, COLD - weakest
2. If a stronger reset is asserted during weaker reset sequence, then the stronger reset will take over and the stronger reset process will commence. The following cases fall into this category:
   - POR reset request in the middle of cold reset process - the cold will be stopped and the POR sequence will start.
3. If a weaker reset is asserted during stronger reset sequence, then the stronger reset sequence will continue without interference. If at the end of the stronger reset process the weaker request is still asserted then the weaker sequence will commence. The following cases fall into this category:
   - COLD reset requests in the middle of POR reset process - the POR process will continue without interference.

4. If a similar reset request is asserted during the process of reset handling, then the process of reset handling will start over (with the same process). The following cases fall into this category:
   - POR reset request in the middle of POR reset process - the POR process will start over.
   - COLD reset request in the middle of COLD reset process - the COLD process will start over.

21.7.3 Boot Mode Control

21.7.3.1 BOOT_MODE Pin Latching

The exact boot sequence is controlled by the values of the BOOT_MODE pins on this device.

The value of the BOOT_MODE pins will be latched after the OCOTP_CTRL asserts the fuse read completion flag. After latching, the values of the BOOT_MODE pins are used to determine the booting options of the core as described in the SRC_SBMRx registers.

The boot mode general purpose bits can be provided to the SRC from either e-fuses or GPIO signals. The gpio_bt_sel e-fuse defines the source to be used to derive the boot information. When gpio_bt_sel is set, e-fuses are used. When cleared, GPIO signals are used.

The boot information is provided in SRC_SBMR1 register. The figure below shows the selection of boot mode information.

</tr>
<tr>
<td><strong>NOTE:</strong></td>
<td>During the time the WDOG event is masked using SRC logic, it is likely that the WDOG Reset Status Register (WRSR) bit 1 (which indicates a WDOG timeout event) will get asserted. software / OS developer must prepare for this case. Re-enabling the WDOG is possible, by unmasking it in SRC, though it must be preceded by servicing the WDOG. However, for the case that the event has been asserted, the status bit (WRSR bit-1) will remain asserted, regardless of servicing the WDOG module. (Hardware reset is the only way to cause the de-assertion of that bit).</td>

### 21.8.2 SRC Boot Mode Register 1 (SRC_SBMR1)

The Boot Mode register (SBMR) contains bits that reflect the status of Boot Mode Pins of the chip. The reset value is configuration dependent (depending on boot/fuses/IO pads).

If SRC_GPR10[28] bit is set, this bit instructs the ROM code to use the SRC_GPR9 register as if it is SBMR1. This allows software to override the fuse bits and boot from an alternate boot source.

Address: 400F_8000h base + 4h offset = 400F_8004h

#### SRC_SBMR1 field descriptions

<td>Refer to fusemap.</td>
</tr>
</tbody>
</table>
21.8.3 SRC Reset Status Register (SRC_SRSR)

The SRSR is a write to one clear register which records the source of the reset events for the chip. The SRC reset status register will capture all the reset sources that have occurred. This register is reset on ipp_reset_b. This is a read-write register.

For bit[6-0] - writing zero does not have any effect. Writing one will clear the corresponding bit. The individual bits can be cleared by writing one to that bit. When the system comes out of reset, this register will have bits set corresponding to all the reset sources that occurred during system reset. Software has to take care to clear this register by writing one after every reset that occurs so that the register will contain the information of recently occurred reset.

Address: 400F_8000h base + 8h offset = 400F_8008h
## SRC_SRSR field descriptions

### SRC_SRSR field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 3 ipp_user_reset_b | Indicates whether the reset was the result of the ipp_user_reset_b qualified reset.  
0  Reset is not a result of the ipp_user_reset_b qualified as COLD reset event.  
1  Reset is a result of the ipp_user_reset_b qualified as COLD reset event. |
| 2 csu_reset_b | Indicates whether the reset was the result of the csu_reset_b input.  
0  Reset is not a result of the csu_reset_b event.  
1  Reset is a result of the csu_reset_b event. |
| 1 lookup_sysresetreq | Indicates a reset has been caused by CPU lockup or software setting of SYSRESETREQ bit in Application Interrupt and Reset Control Register of the Arm core. SW needs to write a value to SRC_GPR5 before writing the SYSRESETREQ bit and use the SRC_GPR5 value to distinguish if the reset is caused by SYSRESETREQ or CPU lockup.  
0  Reset is not a result of the mentioned case.  
1  Reset is a result of the mentioned case. |
| 0 ipp_reset_b | Indicates whether reset was the result of ipp_reset_b pin (Power-up sequence)  
0  Reset is not a result of ipp_reset_b pin.  
1  Reset is a result of ipp_reset_b pin. |
21.8.4 SRC Boot Mode Register 2 (SRC_SBMR2)

The Boot Mode register (SBMR), contains bits that reflect the status of Boot Mode Pins of the chip. The default values for those bits depends on the values of pins/fuses during reset sequence, hence the question mark on their default value.

Address: 400F_8000h base + 1Ch offset = 400F_801Ch

<th>Description</th>
</tr>
</thead>
</table>
| 31    | Read/write bit, for general purpose  
  **NOTE:** Reset only by POR |
| 30    | PERSIST_SECONDARY_BOOT  
  This bit identifies which image must be used - primary and secondary.  
  Used only for eMMC/SD/FlexSPI NOR boot. |
| 29–28 | Read/write bits, for general purpose  
  **NOTE:** Reset only by POR |
| 27–26 | PERSIST_REDUNDANT_BOOT  
  This field identifies which image must be used - 0/1/2/3. Used for both SPI NAND and SLC raw NAND devices. |

Chapter 22
Fusemap

22.1 Boot Fusemap

This section describes the various modes and the selection of the required boot devices.

A separate map is given for each and every boot device. The device select is specified by the BOOT_CFG1[7:4] fuses.

<table>
<thead>

NOTE

The fuses marked as “Reserved” are reserved for NXP internal (and future) use only, or are security related. Customers must not attempt to burn these, because the IC behavior may be unpredictable. The reserved fuses can be read as either '0' or '1'. Security-related fuses are described in the Security Reference Manual (SRM) for this device.

NOTE

Security-related fuses are shown as reserved here. For details, refer to the Security Reference Manual.

23.2 Overview

This section contains information describing the requirements for the on-chip eFuse OTP controller along with details about the block functionality and implementation.

In this document, the words "eFuse" and "OTP" are interchangeable. OCOTP refers to the hardware block itself.
23.2.1 Features

The OCOTP provides the following features:

- 32-bit word restricted program and read to 2 kbit of eFuse OTP.
- Loading and housing of fuse content into shadow registers
- Memory-mapped (restricted) access to shadow registers
- Generation of STICKY_REG which consists of sticky register bits
- Provides program-protect and read-protect eFuse
- Provides override and read protection of shadow register

23.3 Clocks

The table found here describes the clock sources for OCOTP. Please see the chip-specific clocking section for clock setting, configuration and gating information.

<table>

</table>
23.4 Top-Level Symbol and Functional Overview

The figure below shows the OCOTP system level diagram.

![Figure 23-1. OCOTP System Level Diagram](image)

23.4.1 Operation

The IP bus interface of the OCOTP has the following functions.

- Configure control registers for programming and reading all the fuse words
- Override and read shadow registers

OCOTP configuration for programs and reads are performed on 32-bit words for software (SW) convenience. For writes, the 32-bit word reflects the "write-mask." Bit fields with 0 will not be programmed and bit fields with 1 will be programmed. OCOTP will program bit field with 1 in the fuse word one bit by one bit. For reads, OCOTP will read 4 times to get 4 bytes in the fuse word in order.
23.4.1.1 Shadow Register Reload

All fuse words in efusebox are shadowed. Therefore, fuse information is available through memory mapped shadow registers. If fuses are subsequently programmed, the shadow registers should be reloaded to keep them coherent with the fuse bank arrays.

The "reload shadows" feature allows the user to force a reload of the shadow registers without having to reset the device. To force a reload, complete the following steps:

1. Set the HW_OCOTP_TIMING[STROBE_READ] field value appropriately.
2. Set the HW_OCOTP_TIMING[RELAX] field value appropriately.
3. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a new access can be requested.
4. Set the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit. OCOTP will read all the fuses one by one and put it into corresponding shadow register.
5. Wait for HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[RELOAD_SHADOWS] to be cleared by the controller.

The controller will automatically clear the HW_OCOTP_CTRL[RELOAD_SHADOWS] bit after the successful completion of the operation.

23.4.1.2 Fuse and Shadow Register Read

All shadow registers are always readable through the IPS bus. When their corresponding fuse lock bits are set, the shadow registers also become read locked. After read locking, reading from these registers will return 0xBADABADA.

In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write, read or reload access can be issued. Subsequent reads to unlocked shadow locations will still work successfully however.

To read fuse words directly from the fusebox, complete the following steps:

1. Program HW_OCOTP_TIMING[STROBE_READ] and HW_OCOTP_TIMING[RELAX] fields with timing values to match the current frequency of the ipg_clk. OTP read will work at maximum bus frequencies as long as the HW_OCOTP_TIMING parameters are set correctly.
2. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write, read or reload must be completed before a read access can be requested.
3. Write the requested fuse address to HW_OCOTP_CTRL[ADDR].
4. Set HW_OCOTP_READ_CTRL[READ_FUSE] to 1. OCOTP will auto read the fuse word according to HW_OCOTP_CTRL[ADDR] in fusebox. Then put read value into HW_OCOTP_READ_FUSE_DATA
5. Once complete, the controller will clear BUSY. A read request to a protected or locked region will result in no OTP access and no setting of HW_OCOTP_CTRL[BUSY]. In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new access can be issued.
6. Read HW_OCOTP_READ_FUSE_DATA to get fuse word value. HW_OCOTP_READ_FUSE_DATA will be 0xBADABADA when HW_OCOTP_CTRL[ERROR] is set.

23.4.1.3 Fuse and Shadow Register Writes

Shadow register bits can be overridden by software until the corresponding fuse lock bit for the region is set. When the lock shadow bit is set, the shadow registers for that lock region become write locked. The HW_OCOTP_LOCKn register also has no overwrite or fuse lock bits, but it is always read-only.

In order to avoid "rogue" code performing erroneous writes to OTP, a special unlocking sequence is required for writes to the fuse banks. To program fuse bank complete the following steps:

1. Program the following fields with timing values to match the frequency of ipg_clk:
   - HW_OCOTP_TIMING[STROBE_PROG]
   - HW_OCOTP_TIMING[RELAX]
   OTP writes will work at maximum bus frequencies as long as the HW_OCOTP_TIMING parameters are set correctly.
2. Check that HW_OCOTP_CTRL[BUSY] and HW_OCOTP_CTRL[ERROR] are clear. Overlapped accesses are not supported by the controller. Any pending write or reload must be completed before a write access can be requested.
3. Write the requested address to HW_OCOTP_CTRL[ADDR] and program the unlock code into HW_OCOTP_CTRL[WR_UNLOCK]. The unlock code must be programmed for each write access. The unlock code is documented in the register description. Both the unlock code and address can be written in the same operation.
4. Write the data to the HW_OCOTP_DATA register. This will automatically set HW_OCOTP_CTRL[BUSY] and clear HW_OCOTP_CTRL[WR_UNLOCK]. Bit fields with 1's will result in that OTP bit being programmed. Bit fields with 0's will be ignored. At the same time that the write is accepted, the controller makes an internal copy of HW_OCOTP_CTRL[ADDR] which cannot be updated until the next write sequence is initiated. This copy guarantees that erroneous writes to
HW_OCOTP_CTRL[ADDR] will not affect an active write operation. During the write operation, HW_OCOTP_DATA cannot be modified.

5. Once complete, the controller will clear HW_OCOTP_CTRL[BUSY]. A write request to a protected or locked region will result in no OTP access and no setting of HW_OCOTP_CTRL[BUSY]. In addition HW_OCOTP_CTRL[ERROR] will be set. It must be cleared by software before any new write access can be issued.

It should be noted that write latencies to OTP are numbers of 10 micro-seconds per word. The write latency is based on the number of "1" bits being written. For example: to program half the fuse bits in one 32-bit word needs 10 us x 16.

HW_OCOTP_CTRL[ERROR] will be set under the following conditions:

- A write is performed to a shadow register during a shadow reload (essentially, while HW_OCOTP_CTRL[RELOAD_SHADOWS] is set). In addition, the contents of the shadow register shall not be updated.
- A write is performed to a shadow register which has been locked.
- A read is performed to a shadow register which has been read locked.
- A program is performed to a fuse word which has been locked.
- A read is performed to a fuse word which has been read locked.

### 23.4.1.4 Write Postamble

Due to internal electrical characteristics of the OTP during writes, all OTP operations (direct reads, shadow reloads, or other writes) following a write must wait at least 2 µs after the clearing of HW_OCOTP_CTRL[BUSY] following the write. The delay guarantees programming voltages on-chip reach a steady state when exiting a write sequence.

A recommended software sequence to meet the postamble requirements is as follows:

1. Issue the write and poll for HW_OCOTP_CTRL[BUSY].
2. Once HW_OCOTP_CTRL[BUSY] is clear, wait 2 µs.
3. Perform the next OTP operation.

### 23.4.2 Fuse Shadow Memory Footprint

The OTP memory footprint is shown in the following figure. The registers are grouped by lock region. Their names correspond to the fusemap names.
23.4.3 OTP Read/Write Timing Parameters

The timing fields contained in the HW_OCOTP_TIMING register that specify counter limit values, which are used to time how long the state machine remains in the various states, as well as specify the STROBE signal timing.

The timing parameters are specified in ipg_clk cycles. Since the ipg_clk frequency can be set to a range of values, these parameters must be adjusted with the clock to yield the appropriate delay.

<table>
<thead>
<tr>
<th>Register Field</th>
<th>Description</th>
</tr>
</thead>
</table>

Table continues on the next page...
**23.4.4 Behavior During Reset**

The OCOTP is always active. The shadow registers automatically load the appropriate OTP contents after reset is deasserted. During this load-time HW_OCOTP_CTRL[BUSY] is set.

**23.4.5 Secure JTAG control**

The JTAG control fuses are used to allow or disallow JTAG access to secured resources. Three JTAG security levels are implemented as shown in the table below.
### Table 23-3. JTAG Security Level Control Bits

10
RELOAD_SHADOWS
Reload Shadow Registers
This bit can be set to force re-loading of the shadow registers. This operation will automatically set BUSY. After the shadow registers have been re-loaded, BUSY and RELOAD_SHADOWS are automatically cleared by the controller.

0b - Do not force shadow register re-load.
1b - Force shadow register re-load. This bit is cleared automatically after shadow registers are re-loaded.

9
ERROR
Locked Region Access Error
This bit is set by the controller when an access to a locked region (OTP or shadow register) is requested. Reset this bit by writing a one to the CTRL_CLR[ERROR] bit and not by writing to the CTRL register.

0b - No error.
1b - Error - access to a locked region requested.

8
BUSY
OTP controller status bit
This bit is automatically set by the controller when a write or read access to the OTP is started. When set, no new write access or read access to OTP (including RELOAD_SHADOWS) can be performed. This bit is cleared by the controller when an access completes. After reset (or after setting RELOAD_SHADOWS), this bit is set by the controller until the HW/SW and LOCK registers are successfully copied, after which time it is automatically cleared by the controller.

0b - No write or read access to OTP started.
1b - Write or read access to OTP started.

7-6
---
Reserved

5-0
ADDR
OTP write and read access address register
Specifies one of 128 word address locations (0x00 - 0x3F).

#### 23.6.1.4.2 Function

The OCOTP Control and Status Register provides the necessary software interface for performing read and write operations to the On-Chip OTP (One-Time Programmable ROM). The control fields such as WR_UNLOCK, ADDR, BUSY and ERROR may be used in conjunction with the DATA register to perform write operations. Read operations to the On-Chip OTP involve ADDR, BUSY and ERROR bit fields and the READ_CTRL register. The read value is saved in the READ_FUSE_DATA register.

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>LOCK</td>
</tr>
</tbody>
</table>
|        | This bitfield locks the bits in this register.  
|        | 0b - Bits in this register are unlocked.  
|        | 1b - Bits in this register are locked. When set, all of the bits in this register are locked and can not be changed through SW programming. After this bit is set, it can only be cleared by a POR. |

| 30-1   | SPARE    |
|        | Unallocated read/write bits for implementation specific software use. |

| 0      | HAB_JDE  |
|        | HAB JTAG Debug Enable  
|        | This bit can be used by the High Assurance Boot (HAB) portion of the Boot ROM to enable JTAG debugging, assuming that a properly signed command to do so is found and validated by the HAB. The HAB will lock the register before passing control to the application whether or not JTAG debugging has been enabled. Once JTAG is enabled by this bit, it cannot be disabled unless the system is reset by POR.  
|        | 0b - JTAG debugging is not enabled by the HAB (it may still be enabled by other mechanisms).  
|        | 1b - JTAG debugging is enabled by the HAB (though this signal may be gated off). |

Status of shadow register and OTP write lock for gp2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

**GP1 Write Lock Status**

Status of shadow register and OTP write lock for gp2 region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

**MAC_ADDR Write Lock Status**

Status of shadow register and OTP write lock for mac_addr region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

**SJC_RESP Lock Status**

Status of shadow register read and write, OTP read and write lock for sjc.resp region.

0b - The writing or reading of this region's shadow register and OTP fuse word are not blocked.
1b - When set, the writing of this region's shadow register and OTP fuse word are blocked. The read of this region's shadow register and OTP fuse word are also blocked.

**MEM_TRIM Write Lock Status**

Status of shadow register and OTP write lock for mem.trim region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

**BOOT_CFG Write Lock Status**

Status of shadow register and OTP write lock for boot_cfg region. When bit 1 is set, the writing of this region's shadow register is blocked. When bit 0 is set, the writing of this region's OTP fuse word is blocked.

Chapter 24
External Memory Controllers

24.1 Overview

This chip has these external memory interfaces and controllers:

- Smart External Memory Controller (SEMC)
- eSD/eMMC/SDIO Interface
- Quad Serial Peripheral Interface (QSPI)

24.2 Smart External Memory Controller (SEMC) Overview

The SEMC is a multi-standard memory controller optimized for both high-performance and low pin-count. It can support multiple external memories in the same application with shared address and data pins. The interface supported includes SDRAM, NOR Flash, SRAM and NAND Flash, as well as 8080 display interface.

The key features of the SEMC include:

- Support up to 8 memory regions up to 512Mbit per region which can be configured to be memory space of SDRAM, NOR Flash, NAND Flash, SRAM or 8080 display frame buffer
- Chip Select (CS) signals
- Ability to disable SDRAM and NAND controller by separate fuse bit
- Support Address Latch Enable (ALE)
- SDRAM interface
  - Supports both 8-bit and 16-bit modes
  - Up to 512Mb per each Chip Select (CS) and up to 4x CS
- NOR Flash and SRAM interface
  - Supports 16-bit mode
  - Async mode
  - Address and Data Multiplexing (ADM)
  - Support NOR Flash program via IPBus configuration
• 8080 display interface
  • Supports both 8/16/24-bit modes
  • Up to 100MHz
  • Without tearing effect support
• NAND Flash
  • 8/16-bit NAND FLASH,
  • Async mode only
  • Only supports device which is capable of cache read/write operations
  • Only supports page based operation
• Dynamic I/O sharing which enables multiple external memory device in parallel
• Multi-device access pattern scheduler
  • 8 entries scheduler
  • QoS priority, latency and efficiency adjustable arbitration scheme
• SDRAM access pattern optimization
  • 8 entries command reordering queue
  • QoS priority, latency and efficiency adjustable arbitration scheme

24.3 eMMC/eSD/SDIO

This chip has two Ultra Secured Digital Host Controller (uSDHC) modules for SD/ eMMC interface. It provides the interface between the host system and the SD/ SDIO/MMC cards.

The key features include:

• Support SD/SDIO standard, up to version 3.0
• Support MMC standard, up to version 4.5
• Support 3.3V and 1.8V operation, but do not support 1.2V operation.
• Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
  • Up to 800 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR mode
  • Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR mode
  • Up to 800 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR mode
  • Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR mode
  • Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR mode
  • Up to 800 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR mode
24.4 Quad Serial Peripheral Interface

This chip has one Quad Serial Peripheral Interface block (named FlexSPI) acts as an interface to one or two external serial flash devices, each with up to four bidirectional data lines.

The key features includes:

- Each channel can be configured as 1/2/4-bit operation
- Support both dual-channel or single-channel operation
- Support both SDR mode and DDR mode
- Support up to 166MHz SDR Mode and 166MHz DDR Mode (with external Flash device DQS input)
- Support up to 133MHz SDR Mode and 66MHz DDR Mode (with internal DQS loopback mode)

**NOTE**

- For SEMC_CLKX0, see SEMC_CLK5 in IOMUXC chapter.
- For SEMC_CLKX1, see SEMC_CLK6 in IOMUXC chapter.

**NOTE**

Non-ADMUX ASYNC mode for the SRAM operation is depended on pin availability.
25.2 About this module

25.2.1 Introduction

The SEMC is a multi-standard memory controller optimized for both high-performance and low pin-count. It can support multiple external memories in the same application with shared address and data pins. The interface supported includes SDRAM, NOR Flash, SRAM and NAND Flash, as well as 8080 display interface.

25.2.2 Features

The SEMC includes the following features:

- Memory space:
  - Support up to 9 memory regions:
    - Region #0 for SDRAM CS0 device
    - Region #1 for SDRAM CS1 device
    - Region #2 for SDRAM CS2 device
    - Region #3 for SDRAM CS3 device
    - Region #4 and #8 for NAND device (IP command and AXI command use different region to avoid large region address range on AXI interface)
    - Region #5 for NOR device
    - Region #6 for SRAM device
    - Region #7 for 8080 display frame buffer
  - Each region is configurable for base address, memory size and valid bit
- AXI slave interface
  - Support 16 outstanding transfer totally for write and read
  - Support 8 outstanding transfer for write
  - Support 16 outstanding transfer for read
  - Multi-device access pattern optimization with Queue A
    - 8 entries command reordering in Queue A
    - QoS priority, latency and efficiency adjustable arbitration scheme
  - SDRAM access pattern optimization with Queue B
    - 8 entries command reordering in Queue B
    - QoS priority, latency and efficiency adjustable arbitration scheme
  - Trigger device read or write access (AXI command)
  - 32/16/8 bit access supported
  - All burst length supported
  - Only INCR and WRAP burst supported
NOTE
WRAP read/write with 16 bit or 8 bit data size is not supported

• No prefetch/cachable support
• IP Bus interface
  • Internal configuration register access
  • Trigger device access such as device initialization/configuration/read/write (IP command)
• SDRAM interface
  • Support 8/16 bit modes
  • Up to 4 Chip Select (CS) and each CS up to 512Mb
• NAND Flash interface
  • Support 8/16 bit modes
  • No HW ECC
  • Only supports device which is capable of cache read/write operations
  • Only supports page based read/write operation
  • Only supports 32 bit transfer size for AXI write operation
• NOR Flash interface
  • Support 16 bit mode
  • Support ADMUX and AADM modes
  • NOR flash write access is supported only by IP command
  • Up to 512Mb memory size

NOTE
• Up to 512Mb memory size if SEMC_ADDR08 is used as address
• Up to 256Mb memory size if SEMC_ADDR08 is used as chip select

• SRAM interface
  • Support 16 bit mode
  • Support ADMUX and AADM modes
  • Up to 512Mb memory size

NOTE
• Up to 512Mb memory size if SEMC_ADDR08 is used as address
• Up to 256Mb memory size if SEMC_ADDR08 is used as chip select

• 8080 display interface
• Support 8/16 bit modes
• Without tearing effect support
• Misc
  • Dynamic I/O sharing which enables multiple external memory device in parallel
  • Up to 7 Chip Select (CS) signals
  • Ability to disable SDRAM and NAND controller by separate fuse bit
  • Support Address Latch Enable (ALE) for SRAM/NOR device

25.2.3 Operation Modes

SEMC supports following operation modes:

• Module Disable mode

  In module disable mode, internal clock is gated for low power, but access to
  configuration and status registers is available.

  This mode is entered by setting MCR[MDIS], and exited by clearing MCR[MDIS].
  Software should polling STS0[IDLE] to make sure there is no pending transaction
  before entering module disable mode.

• Stop mode

  When the system requires SEMC to enter stop mode (ipg_stop=0x1), SEMC waits
  for all transactions to complete (STS0[IDLE]=0x1) and return acknowledge
  handshake to system (ipg_stop_ack=0x1). The system can gate off SEMC clock after
  acknowledge handshake returned. There is no clock gating action internally.

  SEMC exit this mode immediately when system stop mode request deasserted with
  the acknowledge handshake deasserted.

• Normal mode

  Access to external devices and internal registers are available in normal mode.
  SEMC clock is not gated internally.
25.2.4 Block diagram

### 25.4.1.20.3 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 31-24 ITO | SDRAM Idle timeout  
SEMC closes all opened pages if the SDRAM idle time lasts more than idle timeout period. SDRAM is considered idle when there is no AXI Bus transfer and no SDRAM command pending.  
00000000b - IDLE timeout period is 256*Prescale period.  
00000001-11111111b - IDLE timeout period is ITO*Prescale period. |

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 23-16 ACT2ACT | ACT to ACT wait time  
SEMC promises ACT2ACT+1 clock cycles delay between ACTIVE command to ACTIVE command. This could help to meet tRRD timing requirement by SDRAM device. |

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 15-8 REF2REF | Refresh to Refresh wait time  
SEMC promises REF2REF+1 clock cycles delay between REFRESH command to REFRESH command. This could help to meet tRFC timing requirement by SDRAM device. |

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 7-0 SRRC | Self Refresh Recovery time  
SEMC promises SRRC+1 clock cycles delay between Self-REFRESH command to any command. |

### 25.4.1.39.3 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 31-16 KEY | This field should be written with 0xA55A when triggering an IP command for all device types. The memory device is selected by BRx settings and IPCR0 registers.  
This field should be written with 0x5AA5 when triggering an IP command for NAND only. The address is extended to 40-bit with the use of NAND_EXT_ADDR. NAND IP base address is from 0x0 and memory size is not limited by BR8.MS. |
| 15-0 CMD | SDRAM Commands:  
- 0x8: READ  
- 0x9: WRITE  
- 0xA: MODESET  
- 0xB: ACTIVE  
- 0xC: AUTO REFRESH  
- 0xD: SELF REFRESH  
- 0xE: PRECHARGE  
- 0xF: PRECHARGE ALL  
- Others: RSVD  

**NOTE:** SELF REFRESH is sent to all SDRAM devices because they shared same SEMC_CLK pin.  
NAND Commands:  
Bit 15-8 (Command Code)  
Bit 7-4 (Address mode):  
- 0x0: Column and Row address(5 Byte-CA0/CA1/RA0/RA1/RA2)  
- 0x1: Column address only (1 Byte-CA0)  
- 0x2: Column address only (2 Byte-CA0/CA1)  
- 0x3: Row address only (1 Byte-RA0)  
- 0x4: Row address only (2 Byte-RA0/RA1)  
- 0x5: Row address only (3 Byte-RA0/RA1/RA2)  
- Others: RSVD  

Bit 3-0 (Command mode):  
- 0x0: Command(0x05)-Address-Command-Read (Reserved for AXI Read)  
- 0x1: Command(0x85)-Address-Write (Reserved for AXI Write)  
- 0x2: Command  
- 0x3: Command-Hold  
- 0x4: Command-Address  
- 0x5: Command-Address-Hold  
- 0x6: Command-Address-Read  
- 0x7: Command-Address-Write  
- 0x8: Command-Read  
- 0x9: Command-Write  
- 0xA: Read  
- 0xB: Write  
- Others: RSVD  

NOR Commands:  
- 0x2: READ  
- 0x3: WRITE  
- Others: RSVD  

SRAM Commands:  
- 0x2: Memory ARRAY READ  
- 0x3: Memory ARRAY WRITE
### Field | Function
---|---
• 0x4: Memory register READ
• 0x5: Memory register WRITE
• Others: RSVD

**DBI_B Commands:**
• Others: RSVD
• 0x2: Read
• 0x3: Write

---

25.5 Functional description

The following sections describe functional details of the SEMC module.

25.5.1 Clocks

This section describes clocks and special clocking requirements of the SEMC module.
There is only one clock domain which is used for AXI bus interface, IP bus interface, internal logic and external interface.

### 25.5.2 Reset

This section describes how to reset the SEMC module and explains special requirements related to reset.

### 25.5.3 Pin Mux in SEMC

Following table describes the pin mux in SEMC module.

<table>

</tbody>
</table>

**NOTE**

- Configure register field should be static.
- NOR and SRAM pins are configured as 16 bit ADMUX mode in above table. It is the recommended configuration.

### 25.5.4 Device access by AXI Command

Devices could be read/written by AXI bus access directly. AXI command is the device access sequence triggered by AXI bus access. The device access sequence for AXI command is described in the following sections.
NOTE

- The AXI bus memory map for each device is defined by SEMC_BRx registers.
- There is no software configuration or polling needed for AXI command except SEMC initialization. AXI master access external flash device transparently similar as normal AXI slave.
- AXI command is normally used to read/write access device memory space. IP command should be used to any other access, such as device register/OTP space access, device initialization.
- IP command could be used for memory read/write also similar as AXI command. But it is not recommended if only AXI command is available.

25.5.4.1 BMCR Registers Configuration

BMCR registers can be used to balance external memory access efficiency, urgency and latency based on requirement of a specific applications.

25.5.4.1.1 BMCR0 Registers Configuration

For Queue A controlled by BMCR0, the arbitration logic adopts a weight based algorithm that assigns each command in the reordering queue with a final score.

The arbitration logic calculates a SCORE for each command based on the formula below. The command with the highest SCORE is served first.

\[
\text{SCORE} = \text{QOS} \times \text{WQOS} + \text{AGE} \times \text{WAGE}/4 + \text{WSH} + \text{WRWS}
\]

1. QOS stands for AxQOS of AXI bus, and WQOS is the weight factor of QOS.
2. AGE stands for the wait period for each command in queue, and WAGE is the weight factor of AGE.
3. WSH stands for weight of slave hit without read/write switch scenario.
4. WRWS stands for weight of slave hit with read/write switch scenario.

25.5.4.1.2 BMCR1 Registers Configuration

For Queue B controlled by BMCR1, the arbitration logic adopts a weight based algorithm that assigns each command in the reordering queue with a final score.
The arbitration logic calculates SCORE for each SDRAM command based on the formula below. The command with the highest SCORE is served first.

\[
\text{SCORE} = \text{QOS} \times \text{WQOS} + \text{AGE} \times \text{WAGE}/4 + \text{WPH} + \text{WBR} + \text{WRWS}
\]

1. QOS stands for AxQOS of AXI bus, and WQOS is the weight factor of QOS.
2. AGE stands for the wait period for each command in queue, and WAGE is the weight factor of AGE.
3. WPH stands for weight of page hit scenario.
4. WBR stands for weight of bank rotation scenario.
5. WRWS stands for weight of slave hit without read/write switch scenario.

### 25.5.5 Device access by IP Command

Device could be accessed (initialized/configured/read/written) by IP bus access also. IP command is the device access sequence triggered by IP bus access. The device access sequence for IP command is described in the following sections.

Device access could be triggered by IP command in following steps:

1. Set register IPCR0/IPCR1/IPCR2/IPTXD for Device address/Data Size/Write Data/Write Mask.
2. Set register IPCMD with valid command code (IPCMD.CMD) and command key (IPCMD.KEY).
3. Wait for IP Command Done (Wait for interrupt IPCMDDONE generated).
4. Read the device data from IPRXD. This is needed for read access only.

**NOTE**

- If device address or command code setting is not valid, IP command error interrupt is generated (INTR.IPCMDERR) and no device access at all.
- If another IP command triggered when the previous IP command not finished yet, IP command error interrupt is generated.
- IPCR0/IPCR1/IPCR2/IPTXD is protected when IP command triggered by not finished yet. Any write access to these register is ignored.
- IPCR0 device address field should be configured even the device don't need any address bit information such as WRITE ENABLE command. SEMC need the device address to determine which device should be accessed.
- SEMC can access NAND only if the KEY is 0x5AA5.
25.5.6  SDRAM Controller Operations

This section describes the SDRAM controller module’s operations.

25.5.6.1  SDRAM address map

SDRAM device address map on SoC is indicated in following diagram:

![SDRAM device address map](image)

**Figure 25-2. SDRAM device address map**

25.5.6.2  SDRAM device access by IP Command

Following SDRAM device access could be triggered by IP command:

1. SELF REFRESH  
2. AUTO REFRESH  
3. MODE REGISTER SET  
4. PRECHARGE  
5. PRECHARGE ALL  
6. ACTIVE  
7. READ  
8. WRITE

25.5.6.2.1  IP command - SDRAM Self Refresh

When IP command triggered with command code - SELF REFRESH to any SDRAM device, SEMC would send SELF REFRESH command to all SDRAM devices. After SELF REFRESH command finished, all SDRAM device should be in self refresh state and SEMC keeps this state on SDRAM interface (SEMC_CKE=0x0 and SEMC_CLK=0x0).
SEMC brings all SDRAM device out from self refresh state when there is any new IP command or AXI command triggered to SDRAM device.

Following timing diagram illustrates the sequence for self-refresh entering and exiting by AXI command.

![Figure 25-3. IP command - SDRAM Self Refresh](image)

### 25.5.6.2.2 IP command - SDRAM Auto Refresh

When IP command triggered with command code - AUTO REFRESH, SEMC would send AUTO REFRESH command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - AUTO REFRESH.

![Figure 25-4. IP command - SDRAM Auto Refresh](image)

### 25.5.6.2.3 IP command - SDRAM Mode Register Set

When IP command triggered with command code - Mode Register Set, SEMC would send MODE REGISTER SET command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - MODE REGISTER SET.
25.5.6.2.4 IP command - SDRAM Precharge

When IP command triggered with command code - Precharge, SEMC would send PRECHARGE command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - PRECHARGE.

25.5.6.2.5 IP command - SDRAM Precharge ALL

When IP command triggered with command code - Precharge ALL, SEMC would send PRECHARGE ALL command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - PRECHARGE ALL.
25.5.6.2.6 IP command - SDRAM Active

When IP command triggered with command code - Active, SEMC would send ACTIVE command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - ACTIVE.

25.5.6.2.7 IP command - SDRAM READ

When IP command triggered with command code - READ, SEMC would send READ command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - READ.
25.5.6.2.8 IP command - SDRAM WRITE

When IP command triggered with command code - WRITE, SEMC would send WRITE command to the SDRAM device accessed.

Following timing diagram illustrates the sequence for IP command - WRITE.

25.5.6.3 SDRAM device access by AXI Command

SDRAM device read/write access could be triggered by AXI Command. For AXI read access, SEMC would send READ commands to SDRAM device automatically and return data on AXI bus. For AXI write access, SEMC would save AXI bus write data and send WRITE commands to SDRAM device automatically.
25.5.6.3.1 SDRAM device read access by AXI Command

Following timing diagram illustrates the SDRAM device access triggered by AXI command (Read).

![Figure 25-11. AXI command - SDRAM Read](image)

25.5.6.3.2 SDRAM device write access by AXI Command

Following timing diagram illustrates the SDRAM device access triggered by AXI command (Write).

![Figure 25-12. AXI command - SDRAM Write](image)

25.5.6.3.3 SDRAM device pipelined access by AXI Command

Following timing diagram illustrates the SDRAM device pipelined read access triggered by AXI command (Read).
Following timing diagram illustrates the SDRAM device pipelined write access triggered by AXI command (Write).

25.5.6.3.4  SDRAM back-to-back access

This section describes the SDRAM back-to-back access.

25.5.6.3.4.1  SDRAM read-to-read access

SDRAM read-to-read access timing when CL=1 is as following:
SDRAM read-to-read access timing when CL=2 is as following:

**Figure 25-16. SDRAM Read-to-Read access (CL=2)**

SDRAM read-to-read access timing when CL=3 is as following:

**Figure 25-17. SDRAM Read-to-Read access (CL=3)**
SDRAM read-to-write access timing when CL=1 is as following:

![Figure 25-18. SDRAM Read-to-Write access (CL=1)](image)

SDRAM read-to-write access timing when CL=2 is as following:

![Figure 25-19. SDRAM Read-to-Write access (CL=2)](image)

SDRAM read-to-write access timing when CL=3 is as following:

![Figure 25-20. SDRAM Read-to-Write access (CL=3)](image)
25.5.6.3.4.3 SDRAM write-to-write access

SDRAM write-to-write access timing is as following:

![Figure 25-21. SDRAM Write-to-Write access](image)

25.5.6.3.4.4 SDRAM write-to-read access

SDRAM write-to-read access timing when CL=1 is as following:

![Figure 25-22. SDRAM Write-to-Read access (CL=1)](image)

SDRAM write-to-read access timing when CL=2 is as following:
SDRAM write-to-read access timing when CL=3 is as following:

![Figure 25-24. SDRAM Write-to-Read access (CL=3)](image)

25.5.6.4 Refresh command - SDRAM AUTO Refresh

SEMC would send AUTO REFRESH command to all SDRAM devices when the refresh timer expired and SDRAM Refresh enabled (SDRAMCR3.REN=0x1). Multiple AUTO REFRESH command could be sent if refresh burst is not set to one (SDRAMCR3.REBL!=0x0).

Refresh command is triggered by interval refresh timer period.

Following timing diagram illustrates the sequence for Refresh Command.
25.5.6.5 SDRAM low power feature

This section describes the low power feature implemented for SDRAM.

25.5.6.5.1 Stop mode - SDRAM

When system enter STOP mode, SEMC puts all SDRAM device into self refresh state automatically. When system exit STOP mode, SEMC brings SDRAM device out from self refresh state.

Following timing diagram illustrates the sequence for stop mode entering and exiting.

25.5.6.5.2 BUS Idle - SDRAM

When there is no IP/AXI/Refresh command, SDRAM interface would be in IDLE state (NOP command and chip select invalid). When SDRAM interface bus idle timer expired, SEMC closes all pages opened on all SDRAM devices. Please see SDRAMCR2.ITO for more detail about bus idle timer.
25.5.6.6 SDRAM Page Management

This section describes the SDRAM page management.

There are 8 pages row address saved internally: 4 pages for CS0/CS2 (4 bank), 4 pages for CS1/CS3 (4 bank). Device CS0 and CS2 page is never opened at the same time. Before SEMC open pages on CS2, it closes all opened pages on CS0. This is similar for CS1/CS3.

SEMC close all pages on all CS in following cases:

1. SELF REFRESH triggered by IP command
2. SELF REFRESH triggered by stop mode enter
3. The idle time on AXI bus and SDRAM interface is longer than SDRAM idle timeout time (SDRAMCR2.ITO).

NOTE

SEMC does not sent out PRECHARGE-ALL command if there is no page opened on any bank/CS.

SEMC close all pages on one CS in following cases:

1. PRECHARGE ALL command triggered by IP command
2. AUTO REFRESH command triggered by IP command
3. ACTIVE/WRITE/READ command triggered by IP command and CS miss
4. WRITE/READ command triggered by current AXI command and CS miss
5. WRITE/READ command triggered by next AXI command (not accepted yet), CS miss and not same CS as current AXI command

NOTE

One example for CS miss: Current IP command access CS2 but there is page opened on CS0 already.

SEMC close one page on one CS in following cases:

1. PRECHARGE command triggered by IP command and this bank is opened
2. ACTIVE/READ/WRITE command triggered by IP command, this bank is opened and page missed.
3. WRITE/READ command triggered by current AXI command this bank is opened and page missed.
4. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is opened, page missed and different bank accessed with current AXI command.
NOTE

One example for page miss: current bank is opened but the opened page row address is different with current SDRAM command access.

SEMC open one page on one CS in following cases:

1. ACTIVE/READ/WRITE command triggered by IP command, this bank is not opened.
2. WRITE/READ command triggered by current AXI command this bank is not opened.
3. WRITE/READ command triggered by next AXI command (not accepted yet), this bank is not opened and different bank accessed with current AXI command.

NOTE

One example for page miss: current bank is opened but the opened page row address is different with current SDRAM command access.

25.5.6.7 SDRAM Timers

This section describes the timers used for SDRAM operation

25.5.6.7.1 Prescaler

The prescaler timer in SDRAM controller count freely with the period defined by SDRAM3.PRESCALE. When the prescaler timer expired, urgent refresh timer and SDRAM BUS IDLE timer count by 1.

25.5.6.7.2 Refresh interval timer

The refresh interval timer also count when prescaler timer expires. The timer period is determined by SDRAMCR3.RT and SDRAMCR3.PRESCALE. When refresh interval timer expired, an internal refresh command is triggered and SEMC sends one or multiple AUTO REFRESH command on SDRAM interface.
25.5.6.7.3 Urgent Refresh timer

Urgent refresh timer is used to determine whether current refresh request is urgent or normal. Before urgent refresh timer timeout, refresh request is handled in lower priority than AXI/IP command. When urgent refresh timer timed out, refresh request becomes urgent. SDRAM handles Auto-Refresh command in higher priority than AXI/IP command.

25.5.6.7.4 Beat timer

The beat timer is used to control SDRAM read/write/Auto Refresh command burst length.

25.5.6.7.5 ACTIVE to READ/WRITE timer

The ACTIVE to READ/WRITE timer is used to promise the minimum cycle number between ACITVE command and READ/WRITE command on SDRAM interface.

25.5.6.7.6 PRECHARGE to ACTIVE timer

The PRECHARGE to ACTIVE timer is used to promise the minimum cycle number between PRECHARGE/PRECHARGE ALL command and ACTIVE/AUTO REFRESH/SELF REFRESH command on SDRAM interface.

25.5.6.7.7 CKE OFF timer

The CKEOFF timer is used to promise the minimum cycle of SDRAM CLK off state.

25.5.6.7.8 SELF REFRESH recover timer

The SRRC timer is used to promise the wait time between SDRAM device exit Self Refresh state and sending new Commands to device. SDRAM device may have limitation on Self Refresh recovery time. Before this recovery time expire, any command to device may cause unexpected behavior.

25.5.6.7.9 AUTO REFRESH recover timer

The RFRC timer is used to promise the minimum cycle number between Auto Refresh command and ACTIVE command on SDRAM interface. SDRAM device may have limitation on Refresh recovery time. Before this recovery time expire, any command to device may cause unexpected behavior.
25.5.6.7.10 Refresh to Refresh timer

The refresh to refresh timer is used to promise the minimum cycle number between Auto Refresh command and Auto Refresh command on SDRAM interface.

25.5.6.7.11 ACTIVE to ACTIVE timer

There are two ACT2ACT timer in SDRAM controller. ACT2ACT0 timer is used to promise the minimum cycle number between ACTIVE command and ACTIVE command on CS0/2 device. ACT2ACT1 timer is used to promise the minimum cycle number between ACTIVE command and ACTIVE command on CS1/3 device.

25.5.6.7.12 ACTIVE to PRECHARGE timer

There are two ACT2PRE timer in SDRAM controller. ACT2PRE0 timer is used to promise the minimum cycle number between ACTIVE command and PRECHARGE/PRECHARGE ALL command on CS0/2 device. ACT2PRE1 timer is used to promise the minimum cycle number between ACTIVE command and PRECHARGE/PRECHARGE ALL command on CS1/3 device.

25.5.6.7.13 Write recovery timer

The WRC timer is used to promise the minimum cycle number between WRITE command and PRECHARGE/PRECHARGE ALL command on SDRAM interface. SDRAM device may have limitation on WRITE recovery time. Before this recovery time expire, PRECHARGE/PRECHARGE ALL command to device may cause the write process failed.

25.5.7 NAND Flash Controller Operations

This section describes the NAND Flash controller module’s operations.

25.5.7.1 NAND Flash address map

NAND Flash device address map on SoC is indicated in the following diagram:
25.5.7.2 NAND Flash access address type

There are 6 type address type access provided:

- One Byte Column address
- Two Byte Column address
- One Byte Row address
- Two Byte Row address
- Three Byte Row address
- Five Byte Row/Column address

For IP command, address type is determined by IPCMD register; For AXI command, address type is fixed to "Two Byte Column Address" because all NAND Flash access is in NAND page boundary.

25.5.7.2.1 One Byte Column Address

One Byte column address type access is indicated as following:
25.5.7.2.2 Two Byte Column Address

Two Byte column address type access is indicated as following:

![Diagram of Two Byte Column Address]

Figure 25-29. NAND Flash access Address type - Two Byte Column Address

25.5.7.2.3 One Byte Row Address

One Byte row address type access is indicated as following:
25.5.7.2.4  Two Byte Row Address

Two Byte row address type access is indicated as following:

![Figure 25-31. NAND Flash access Address type - Two Byte Row Address](image)

25.5.7.2.5  Three Byte Row Address

Three Byte row address type access is indicated as following:

![Figure 25-31. NAND Flash access Address type - Two Byte Row Address](image)
25.5.7.2.6 Five Byte Row/Column Address

Five Byte row/column address type access is indicated as following:

There are some option bits provide to support more NAND address type access. Five byte row/column address type could be overried as following:

Table 25-2. Address byte order for Row/Column Address five Byte mode

25.5.7.3 NAND Flash access command type

NAND Flash access support following command types:

1. Command Phase Only
2. Command + Wait Phase
3. Command + Address Phase
4. Command + Address + Wait Phase
5. Command + Address + Read Phase
6. Command + Address + Write Phase (For IP command)
7. Command + Write Phase
8. Command + Read Phase
9. Write Phase Only
10. Read Phase Only
11. Command + Address + Command + Read Phase (For AXI command - Read)
12. Command + Address + Write Phase (For AXI command - Write)

25.5.7.3.1 Command Phase Only

NAND Flash Command Phase Only access is indicated as following:
25.5.7.3.2 Command + Wait Phase

NAND Flash Command + Wait Phase access is indicated as following:

25.5.7.3.3 Command + Address Phase

NAND Flash Command + Address Phase access is indicated as following:
25.5.7.3.4 Command + Address + Wait Phase

NAND Flash Command + Address + Wait Phase access is indicated as following:

![Diagram of Command + Address + Wait Phase](image)

**Figure 25-37. NAND Flash access command type - Command + Address + Wait Phase**

25.5.7.3.5 Command + Address + Read Phase

NAND Flash Command + Address + Read Phase access is indicated as following:

![Diagram of Command + Address + Read Phase](image)
25.5.7.3.6 Command + Address + Write Phase (For IP command)

NAND Flash Command + Address + Write Phase access is indicated as following:

Figure 25-39. NAND Flash access command type - Command + Address + Write Phase

25.5.7.3.7 Command + Read Phase

NAND Flash Command + Read Phase access is indicated as following:
25.5.7.3.8 Command + Write Phase

NAND Flash Command + Write Phase access is indicated as following:

Figure 25-41. NAND Flash access command type - Command + Write Phase

25.5.7.3.9 Read Phase Only

NAND Flash Read Phase Only access is indicated as following:
Figure 25-42. NAND Flash access command type - Read Phase Only

25.5.7.3.10 Write Phase Only

NAND Flash Write Phase Only access is indicated as following:

Figure 25-43. NAND Flash access command type - Write Phase Only

25.5.7.3.11 Command + Address + Command + Read Phase
NAND Flash Command + Address + Command + Read Phase access is indicated as follows:

**Figure 25-44. NAND Flash access command type - Command + Address + Command + Read Phase**

### 25.5.7.3.12 Command + Address + Write Phase (For AXI command)

NAND Flash Command + Address + Write Phase access is indicated as following:

**Figure 25-45. NAND Flash access command type - Command + Address + Write Phase**

### 25.5.7.4 NAND Flash read access EDO and non-EDO mode

NAND Flash read access could be done in EDO or non-EDO mode. The timing indicated as following:

**Figure 25-46. NAND Flash Read Access in EDO or non-EDO mode**
25.5.7.5 NAND Flash access in SYNC mode

NAND Flash supports SYNC mode, the timings are indicated as followings:

25.5.7.5.1 NAND Read Operation in SYNC Mode

NAND read operation in SYNC mode is indicated in following diagram:

![Figure 25-47. NAND Read in SYNC mode](image)

25.5.7.5.2 NAND Write Operation in SYNC Mode

NAND write operation in SYNC mode is indicated in following diagram:

![Figure 25-48. NAND Write in SYNC mode](image)

25.5.7.5.3 NAND Command + Address + Command + Read Operation in SYNC Mode

NAND Command + Address + Command + Read operation in SYNC mode is indicated in following diagram:
25.5.7.5.4 NAND Command + Address + Write Operation in SYNC Mode

NAND Command + Address + Write operation in SYNC mode is indicated in following diagram:

**Figure 25-50. NAND Command + Address + Write in SYNC mode**

25.5.8 NOR Flash Controller Operations

This section describes the NOR Flash controller module’s operations.

25.5.8.1 NOR Flash address map

NOR Flash device address map on SoC is indicated in the following diagram:
NOR device address map when NORCR0.PS=0x1 (16 bit mode)

<table>
<thead>
<tr>
<th>31</th>

</tr>
</tbody>
</table>

Figure 25-51. NOR Flash Address Map

25.5.8.2 NOR Flash Read Operation in ASYNC Mode

Flash read operation in ASYNC mode is indicated in following diagrams:

Figure 25-52. Flash Read in ASYNC mode (ADMUX)

Figure 25-53. Flash Read in ASYNC mode (AADM)

25.5.8.3 NOR Flash Write Operation in ASYNC mode

Flash write operation in ASYNC mode is indicated in following diagrams:
25.5.8.4  NOR Flash Read Operation in SYNC mode

Flash read operation in SYNC mode is indicated in following diagrams:

Figure 25-56. Flash Read in SYNC mode (ADMUX)
25.5.8.5 NOR Flash Write Operation in SYNC mode

Flash write operation in SYNC mode is same as asynchronous.

25.5.9 SRAM Controller Operations

This section describes the SRAM controller module’s operations.

25.5.9.1 SRAM Flash address map

SRAM Flash device address map on SoC is indicated in the following diagram:

SRAM device address map when SRAMCR0.PS=0x1 (16 bit mode)

<table>
<thead>
<tr>
<th>31</th>

</tbody>
</table>
25.5.9.2  SRAM Read Operation in ASYNC Mode

SRAM read operation in ASYNC mode is indicated in following diagrams:

Figure 25-59. SRAM Read in ASYNC mode (ADMUX)

Figure 25-60. SRAM Read in ASYNC mode (AADM)

25.5.9.3  SRAM Write Operation in ASYNC mode

SRAM write operation in ASYNC mode is indicated in following diagrams:

Figure 25-61. SRAM Write in ASYNC mode (ADMUX)
25.5.9.4  SRAM Read Operation in SYNC mode

SRAM read operation in SYNC mode is indicated in following diagrams:

![Figure 25-63. SRAM Read in SYNC mode (ADMUX)](image)

25.5.9.5  SRAM Write Operation in SYNC mode

SRAM write operation in SYNC mode is indicated in following diagrams:
25.5.10 Display Bus Interface Controller Operations

DBI read/write operation indicated as following.

---

**Figure 25-65. DBI Write Operation**

---

**Figure 25-66. DBI Read Operation**
NOTE

- Read access to DBI is always handled as DBI DATA READ transaction.
- Write access to DBI is handled as DBI COMMAND WRITE transaction if address is higher than 0x10000 (with DBI Base address removed). Otherwise, it is handled as DBI DATA WRITE transaction.
- DBI address is not sent to device at all. Only used to determine DBI COMMAND or DATA WRITE.
- DBI bus never sent out address information for COMMAND WRITE, DATA WRITE and DATA READ command.
- AXI WRAP write access to DBI is supported.
- AXI WRAP read access to DBI is not supported except when the first beat address offset is zero in the burst.
- DBI bus interface doesn't support WRITE MASK feature.
- All write strobe in AXI write access to DBI should be valid (one). If AXI write strobe is invalid (zero), SEMC sends write data 8'h00 instead of original write data.
- When DBI bus is 16 bit (DBICR0.PS=0x1), AXI command or IP command access (both read and write) start address to DBI bus should be 16 bit aligned. Otherwise the read data is unknown or the write data to DBI may be wrong. There is no bus error response or internal error status generated for this case.

On this device, for data transfer modes, uSDHC1 only supports 1-bit and 4-bit modes, while uSDHC2 can support 1-bit, 4-bit and 8-bit modes.

NOTE
HS400 mode is not supported on this device.

26.2 Overview

The Ultra Secured Digital Host Controller (uSDHC) provides the interface between the host system and the SD/SDIO/MMC cards, as depicted in Figure 26-1.

The uSDHC acts as a bridge, passing host bus transactions to the SD/SDIO/MMC cards by sending commands and performing data accesses to/from the cards.

It handles the SD/SDIO/MMC protocols at the transmission level.

The following are brief descriptions of the cards supported by the uSDHC:
The Multi Media Card (MMC) is a universal low cost data storage and communication media designed to cover a wide array of applications including mobile video and gaming. Previous MMC cards were based on a 7-pin serial bus with a single data pin, while the new high speed MMC communication is based on an advanced 11-pin serial bus designed to operate in the low voltage range.

The Secure Digital Card (SD) is an evolution of the old MMC technology. It is specifically designed to meet the security, capacity, performance, and environment requirements inherent in newly-emerging audio and video consumer electronic devices. The physical form factor, pin assignment and data transfer protocol are forward-compatible with the old MMC (with some additions).

Under the SD protocol, it can be categorized into Memory card, I/O card and Combo card, which has both memory and I/O functions. The memory card invokes a copyright protection mechanism that complies with the security of the SDMI standard. The I/O card, which is also known as SDIO card, provides high-speed data I/O with low power consumption for mobile electronic devices. For the sake of simplicity, the following figure does not show cards with reduced size or mini cards.
Figure 26-2. ultra Secure Digital Host Controller Block Diagram
26.2.1 Features

The features of the uSDHC module include the following:

- Conforms to the SD Host Controller Standard Specification version 2.0/3.0
- Compatible with the MMC System Specification version 4.2/4.3/4.4/4.41/4.5
- Compatible with the SD Memory Card Specification version 3.0 and supports the Extended Capacity SD Memory Card
- Compatible with the SDIO Card Specification version 2.0/3.0
- Designed to work with SD Memory, miniSD Memory, SDIO, miniSDIO, SD Combo, MMC, MMC plus, and MMC RS cards
- Card bus clock frequency up to 208 MHz
- Supports 1-bit / 4-bit SD and SDIO modes, 1-bit / 4-bit / 8-bit MMC modes
  - Up to 832 Mbps of data transfer for SDIO cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDIO card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 832 Mbps of data transfer for SDXC cards using 4 parallel data lines in SDR(Single Data Rate) mode
  - Up to 400 Mbps of data transfer for SDXC card using 4 parallel data lines in DDR(Dual Data Rate) mode
  - Up to 1600 Mbps of data transfer for MMC cards using 8 parallel data lines in SDR(Single Data Rate) mode
  - Up to 832 Mbps of data transfer for MMC cards using 8 parallel data lines in DDR(Dual Data Rate) mode
- Supports single block/multi-block read and write
- Supports block sizes of 1 ~ 4096 bytes
- Supports the write protection switch for write operations
- Supports both synchronous and asynchronous abort
- Supports pause during the data transfer at block gap
- Supports SDIO Read Wait and Suspend Resume operations
- Supports Auto CMD12 for multi-block transfer
- Host can initiate non-data transfer command while data transfer is in progress
- Allows cards to interrupt the host in 1-bit and 4-bit SDIO modes, also supports interrupt period
- Embodies a fully configurable 128x32-bit FIFO for read/write data
- Supports internal DMA capabilities
- Support voltage selection by configuring vendor specific register bit
- Supports Advanced DMA to perform linked memory access
26.2.2 Modes and Operations

26.2.2.1 Data transfer Modes

The uSDHC can select the following modes for data transfer:

- SD 1-bit
- SD 4-bit
- MMC 1-bit
- MMC 4-bit
- MMC 8-bit
- Identification Mode (up to 400 kHz)
- MMC full speed mode (up to 26 MHz)
- MMC high speed mode (up to 52 MHz)
- MMC HS200 mode (up to 200 MHz)
- MMC DDR mode (52 MHz both edges)
- SD/SDIO full speed mode (up to 25 MHz)
- SD/SDIO high speed mode (up to 50 MHz)
- SD/SDIO UHS-I mode (up to 208 MHz in SDR mode, up to 50 MHz in DDR mode)

Note: IP can support the above-listed speed mode and max clock frequency. For SOC, speed mode and max clock frequency should be specific to chip. See the corresponding chip description for details.

26.3 External Signals

The following table describes the external signals of uSDHC:

### 26.3.1 Signals Overview

The uSDHC has 14 associated I/O signals.

- The CLK is an internally generated clock used to drive the MMC, SD, SDIO cards.
- The CMD I/O is used to send commands and receive responses to and from the card. Eight data lines (DAT7~DAT0) are used to perform data transfers between the uSDHC and the card.
- The CD and WP are card detection and write protection signals directly routed from the socket. These two signals are active low (0). A low on CD_B means that a card is inserted, and a high on WP means that the write protect switch is active.
• LCTL is an output signal used to drive an external LED to indicate that the SD interface is busy.
• RST is an output signal used to reset the MMC card.
• VSELECT is an output signal used to change the voltage of the external power supplier.

CD, WP, LCTL, RST and VSELECT are all optional for system implementation. If the uSDHC needs to support a 4-bit data transfer, DAT7~DAT4 can also be optional and tied to high. If the uSDHC does not support HS400 mode, STROBE can also be optional and tied to low.

26.4 Clocks

The table found here describes the clock sources for uSDHC.

</table>

26.5 Functional Description

The following sections provide a brief functional description of the major system blocks, including the Data Buffer, DMA AHB interface, register bank as well as IP Bus interface, dual-port memory wrapper, data/command controller, clock & reset manager and clock generator.

26.5.1 Data Buffer

The uSDHC uses one configurable data buffer to transfer data between the system bus (IP Bus or AHB Bus) and the SD card in an optimized manner, maximizing throughput between the two clock domains (IP peripheral clock and the master clock).
The buffer is used as temporary storage for data being transferred between the host system and the card. The watermark levels for read and write are both configurable and can be from 1 to 128 words. The burst lengths for read and write are also configurable and can be from 1 to 31 words.

There are 2 transfer modes to access the data buffer:

- **CPU polling mode:**
  - For a host read operation, when the number of words received in the buffer meets or exceeds the RD_WML watermark value, by polling the BRR bit, the Host Driver can read the Buffer Data Port register to fetch the amount of words set in the RD_WML register from the buffer. The write operation is similar.

- **Internal DMA mode (includes simple and advanced DMA accesses):**
  - The internal DMA access, either by simple or advanced DMA, is over the AHB bus.
  - The burst type is always INCR mode and the burst length depends on the shortest of following factors:
    - Burst length configured in the burst length field of the Watermark Level register
    - Watermark Level boundary

![Figure 26-3. uSDHC Buffer Scheme](image-url)
• Block size boundary
• Data boundary configured in the current descriptor (if the ADMA is active)
• 1 Kbyte address boundary defined in the AHB protocol

Write operation is similar.

Sequential and contiguous access is necessary to ensure the pointer address value is correct. Random or skipped access is not possible. The byte order, by reset, is little endian mode. The actual byte order is swapped inside the buffer, according to the endian mode configured by software (see the following figures). For a host write operation, byte order is swapped after data is fetched from the buffer and ready to send to the SD Bus. For a host read operation, byte order is swapped before the data is stored in the buffer.

![Figure 26-4. Data Swap between System Bus and uSDHC Data Buffer in Byte Little Endian Mode](image1)

![Figure 26-5. Data Swap between System Bus and uSDHC Data Buffer in Half Word Big Endian Mode](image2)

### 26.5.1.1 Write Operation Sequence

There are 2 ways to write data into the buffer when the user transfers data to the card:

- Processor core polling through the BWR bit in Interrupt Status register (interrupt or polling)
- Internal DMA
When the internal DMA is not used, (the DMAEN bit in the Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of buffer space exceeds the value set in the WR_WML register, and is ready for receiving new data. At the same time, the uSDHC sets the BWR bit. The buffer write ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the contents of the DMA System Address register to obtain the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the write operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

The uSDHC will not start data transmission until the number of words set in the WR_WML register can be held in the buffer. If the buffer is empty and the Host System does not write data in time, the uSDHC will stop the CLK to avoid the data buffer under-run situation.

26.5.1.2 Read Operation Sequence

There are 2 ways to read data from the buffer when the user transfers data to the card:

- Processor core polling through the BRR bit in Interrupt Status register (interrupt or polling)
- Internal DMA

When internal DMA is not used (DMAEN bit in Transfer Type register is not set when the command is sent), the uSDHC asserts a DMA request when the amount of data exceeds the value set in the RD_WML register, that is available and ready for system fetching data. At the same time, the uSDHC sets the BRR bit. The buffer read ready interrupt will be generated if it is enabled by software.

When internal DMA is used, the uSDHC will not inform the system before all the required number of bytes are transferred (if no error was encountered). When an error occurs during the data transfer, the uSDHC will abort the data transfer and abandon the current block. The Host Driver should read the content of the DMA System Address register to get the starting address of the abandoned data block. If the current data transfer is in multi-block mode, the uSDHC will not automatically send CMD12, even though the
AC12EN bit in the Transfer Type register is set. The Host Driver sends CMD12 in this scenario and re-starts the read operation from that address. It is recommended that a Software Reset for Data be applied before the transfer is re-started.

For any write transfer mode, the uSDHC will not start data transmission until the number of words set in the RD_WML register are in the buffer. If the buffer is full and the Host System does not read data in time, the uSDHC will stop the CLK to avoid the data buffer over-run situation.

### 26.5.1.3 Data Buffer and Block Size

The user needs to know the buffer size for the buffer operation during a data transfer to utilize it in the most optimized way. In the uSDHC, the only data buffer can hold up to 128 words (32-bit) and the watermark levels for write and read can be configured accordingly.

For both read and write, the watermark level can be from 1 to 128 words. For both read and write the burst length can be from 1 to 31 words. The Host Driver may configure the value according to the system situation and requirement.

During a multi-block data transfer, the block length can be set to any value between 1 and 4096 bytes, satisfying the requirements of the external card. The only restriction is from the external card, which can be limited in size or support of a partial block access (which is not the integer times of 512 bytes).

As uSDHC treats each block individually, for block sizes which are not multiples of four (not word-aligned) stuffed bytes are required at the end of each block. For example, if the block size is 7 bytes and there are 12 blocks to write, the system side must write two times for each block. For each block the ending byte will be abandoned by uSDHC because it only sends 7 bytes to the card and picks data from the following system write, resulting in 24 beats of write access in total.

### 26.5.1.4 Dividing Large Data Transfer

This SDIO command CMD53 definition limits the maximum data size of data transfers according to the following formula:

\[
\text{Max data size} = \text{Block size} \times \text{Block count}
\]

The length of a multiple block transfer needs to be in block size units. If the total data length can't be divided evenly into a multiple of the block size, then there are two ways to transfer the data which depend on the function and the card design. Option 1 is for the Host Driver to split the transaction. The remainder of the block size data is then
transferred by using a single block command at the end. Option 2 is to add dummy data in the last block to fill the block size. For option 2, the card must manage the removal of the dummy data.

See the figure below for an example showing the dividing of large data transfers, assuming a kind of WLAN SDIO card that only supports a block size up to 64 bytes. Although the uSDHC supports a block size of up to 4096 bytes, the SDIO can only accept a block size less than 64 bytes, so the data must be divided (see example below).
26.5.2 DMA AHB Interface

The internal DMA implements a DMA engine and the AHB master. When the internal DMA is enabled, the uSDHC_dreq_b will not be asserted during the transfer, but the BWR and BRR bits will be set if the BWRSEN and BRRSEN bits have been set in the Interrupt Status Enable register.

See the figure below for an illustration of the DMA AHB interface block.

![Diagram of DMA AHB Interface Block](image)

**Figure 26-7. DMA AHB Interface Block**

26.5.2.1 Internal DMA Request

If the watermark level requirement is met in data transfer or if the last data of current block is ready in the data buffer, and the Internal DMA is enabled, the Data Buffer block will send a DMA request to AHB interface.

The delay in response from the internal DMA engine depends on the system AHB bus loading and the priority assigned to the uSDHC. The DMA engine does not respond to the request during its burst transfer, but is ready to serve as soon as the burst is over. The Data Buffer de-asserts the request if the data buffer space (for write) or bytes in data buffer is smaller than the watermark level. Upon access to the buffer by internal DMA, the Data Buffer updates its internal buffer pointer, and when the watermark level is satisfied or the last data of current block is ready in the data buffer, another DMA request is sent.
The data transfer is in the block unit, and the subsequent watermark level is always set as the remaining number of words. For instance, for a multi block data read with each block size of 31 bytes, and the burst length set to 6 words. After the first burst transfer, if there are more than 2 words in the buffer (which might contain some data of the next block), another DMA request is sent. This is because the remaining number of words to send for the current block is \((31 - 6 \times 4) / 4 = 2\). The uSDHC will read 2 words out of the buffer, with 7 valid bytes and 1 stuffed byte.

26.5.2.2 DMA Burst Length

Just like a CPU polling access, the DMA burst length for the internal DMA engine can be from 1 to 16 words. The actual burst length for the DMA depends on the lesser of the configured burst length or the remaining words of the current block.

See the example in Internal DMA Request. After 6 words are read, the burst length will be 2 words, then the next burst length will be 6 words. This is because the next block starts, which is 31 bytes, more than 6 words. The Host Driver may take this variable burst length into account. It is also acceptable to configure the burst length as the divisor of the block size, so that each time the burst length will be the same.

26.5.2.3 AHB Master Interface

It is possible that the internal AHB DMA engine could fail during the data transfer. Upon detection of an AHB bus error during DMA transfer, the DMA engine stops the transfer and goes to the idle state. At that point, the internal data buffer stops receiving incoming data and sending out data. The DMAE bit in the Interrupt Status register will be generated to host CPU to report a bus error condition.

Once the DMAE interrupt is received, the software shall send a CMD12 to abort the current transfer and read the DS_ADDR bits of the DMA System Address register to get the starting address of the corrupted block. After the DMA error is fixed, the software should apply a data reset and re-start the transfer from this address to recover the corrupted block. DMA operation will resume when the interrupt is serviced by software.

26.5.2.4 ADMA Engine

In the SD Host Controller Standard, a new DMA transfer algorithm called the ADMA (Advanced DMA) is defined. For Simple DMA, once the page boundary is reached, a DMA interrupt will be generated and the new system address shall be programmed by the Host Driver.
The ADMA defines the programmable descriptor table in the system memory. The Host Driver can calculate the system address at the page boundary and program the descriptor table before executing ADMA. It reduces the frequency of interrupts to the host system. Therefore, higher speed DMA transfers could be realized since the Host MCU intervention would not be needed during long DMA based data transfers.

There are two types of ADMA: ADMA1 and ADMA2 in Host Controller. ADMA1 can support data transfer of 4KB aligned data in system memory. ADMA2 improves the restriction so that data of any location and any size can be transferred in system memory. Their formats of Descriptor Table are different.

ADMA can recognize all kinds of descriptors define in SD Host Controller Standard, and if 'End' flag is detected in the descriptor, ADMA will stop after this descriptor is processed.

### 26.5.2.4.1 ADMA Concept and Descriptor Format

For ADMA1, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Set data length descriptor.
- Set data address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

For ADMA2, including the following descriptors:

- Valid/Invalid descriptor.
- Nop descriptor.
- Rsv descriptor.
- Set data length & address descriptor.
- Link descriptor.
- Interrupt flag and End flag in descriptor.

ADMA will start read/write operation after it reaches the Tran state, using the data length and data address analyzed from most recent descriptor(s).

For ADMA1, the valid data length descriptor is the last Set type descriptor before Tran type descriptor. Every Tran type will trigger a transfer, and the transfer data length is extracted from the most recent Set type descriptor. If there is no Set type descriptor after the previous Trans descriptor, the data length will be the value for previous transfer, or 0 if no Set descriptor is ever met.
Functional Description

For ADMA2, Tran type descriptor contains both data length and transfer data address, so only a Tran type descriptor can start a data transfer.

See the figure below for the format of the descriptor table for ADMA1.

**Figure 26-10. Format of the ADMA2 Descriptor Table**
26.5.2.4.2 ADMA Interrupt

If the interrupt flag descriptor is set, ADMA will generate an interrupt according to various types of descriptors:

For ADMA1:

- Set type of descriptor: interrupt is generated when data length is set.
- Tran type descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop type of descriptor: interrupt is generated just after this descriptor is fetched.

For ADMA2:

- Tran type of descriptor: interrupt is generated when this transfer is complete.
- Link type of descriptor: interrupt is generated when new descriptor address is set.
- Nop/Rsv type of descriptor: interrupt is generated just after this descriptor is fetched.
26.5.2.4.3 ADMA Error

The ADMA will stop whenever any error is encountered. These errors include:

- Fetching descriptor error
- AHB response error
- Data length mismatch error

An ADMA descriptor error will be generated when it fails to detect a 'Valid' flag in the descriptor. If an ADMA descriptor error occurs, the interrupt is not generated even if the 'Interrupt' flag of this descriptor is set.

When BLKCNTEN bit is set, data length set in buffer must be equal to the whole data length set in descriptor nodes, otherwise data length mismatch error will be generated.

When BLKCNTEN bit is not set, then whole data length set in descriptor should be a multiple of block lengths; otherwise, when data set in the descriptor nodes are not performed at block boundaries, then data mismatch errors will occur.

26.5.3 Register Bank with IP Bus Interface

Register accesses via the IP Bus interface are actually on the Register Bank.

See the figure below for the block diagram.
Only 32-bit access is allowed, and no partial read / write is supported, thus all accesses are word aligned.

### 26.5.3.1 SD Protocol Unit

The SD protocol unit deals with all SD protocol affairs.

The SD Protocol Unit performs the following functions:

- Acts as the bridge between the internal buffer and the SD bus
- Sends the command data as well as its argument serially
- Stores the serial response bit stream into corresponding registers
- Detects the bus state on the CMD/DAT lines
- Monitors the interrupt from the SDIO card
- Asserts the read wait signal
- Gates off the SD clock when buffer is announcing danger status
- Detects the write protect state

The SD Protocol Unit consists of four sub modules:

1. SD control misc.
2. Command control.
3. Data control.
4. Clock control

26.5.3.2 SD control misc

In the SD control misc unit, the card detect (include the CD_B and DATA3 used as Card Detection), write protection and card interrupt are implemented.

This module monitors the signal level on all 8 data lines, the command lines, and directly routes the level values into the Register Bank. The driver can use this for debug purposes.

The module also detects the WP (Write Protect) line. If WP is active, writes to the register bank will be ignored.

This module also drives the LCTL output signal when the LCTL bit is set by the driver.

26.5.3.3 SD Clock control

If the internal data buffer is near full (for read) or near empty (for write), the SD clock must be gated off to avoid buffer over/under-run, this module will assert the gate of the output SD clock to shut the clock off. After the buffer has space (for read) or has data (for write), the clock gate of this module will open and the SD clock will be active again.

26.5.3.4 Command control

The Command Control module deals with the transactions on the CMD line.

See the figure below for an illustration of the structure for the Command CRC Shift Register.
The CRC polynomials for the CMD are as follows:

Generator polynomial: \( G(x) = x^7 + x^3 + 1 \)
\( M(x) = \text{(first bit)} \cdot x^n + \text{(second bit)} \cdot x^{n-1} + \ldots + \text{(last bit)} \cdot x^0 \)
\( \text{CRC}[6:0] = \text{Remainder} \left[ (M(x) \cdot x^7) / G(x) \right] \)

26.5.3.5 Data control

The Data Agent deals with the transactions on the eight data lines. Moreover, this module also detects the busy state on the DATA0 line, and generates the Read Wait state by the request from the Transceiver.

The CRC polynomials for the DATA are as follows:

Generator polynomial: \( G(x) = x^{16} + x^{12} + x^5 + 1 \)
\( M(x) = \text{(first bit)} \cdot x^n + \text{(second bit)} \cdot x^{n-1} + \ldots + \text{(last bit)} \cdot x^0 \)
\( \text{CRC}[15:0] = \text{Remainder} \left[ (M(x) \cdot x^{16}) / G(x) \right] \)

26.5.4 Clock & Reset Manager

This module controls all the reset signals within the uSDHC.

There are four kinds of reset signals within uSDHC:

1. Hardware reset.
2. Software reset for all logic.
3. Software reset for the data logic.
4. Software reset for the command logic.

All these signals are fed into this module and stable signals are generated inside the module to reset all other modules. The module also gates off all the inside signals.
26.5.5 Clock Generator

The Clock Generator generates the card CLK by peripheral source clock in two stages. Refer to the figure below for the structure of the divider. The term "Base" represents the frequency of peripheral source clock.

![Figure 26-14. Two Stages of the Clock Divider](image)

The first stage outputs an intermediate clock (DIV), which can be Base, Base/2, Base/3, ..., or Base/16.

The second stage is a prescaler, and outputs the actual internal working clock (card_clk). This clock is the driving clock for all sub modules of the SD Protocol Unit, and the sync FIFOs (see Figure 26-3) to synchronize with the data rate from the internal data buffer. The frequency of the clock output from this stage, can be DIV, DIV/2, DIV/4, ..., or DIV/256. Thus the highest frequency of the card_clk is Base, and the next highest is Base/2, while the lowest frequency is Base/4096. If the duty cycle of Base clock is 50%, the duty cycle of card_clk is also 50%, even when the compound divisor is an odd value.

Please note, in SDR mode and DDR mode, the CLK are different.
- In SDR mode, CLK is equal to the internal working clock(card_clk).
- In DDR mode, CLK is equal to the card_clk/2.

26.5.6 SDIO Card Interrupt

Information on Interrupts in 1-bit Mode, Interrupts in 4-bit Mode, and Card Interrupt Handling are detailed in the sections below.

26.5.6.1 Interrupts in 1-bit Mode

In this case the DATA1 pin is dedicated to providing the interrupt function. An interrupt is asserted by pulling the DATA1 low from the SDIO card, until the interrupt service is finished to clear the interrupt.
26.5.6.2 Interrupt in 4-bit Mode

Since the interrupt and data line 1 share Pin 8 in 4-bit mode, an interrupt will only be sent by the card and recognized by the host during a specific time. This is known as the Interrupt Period. The uSDHC will only sample the level on Pin 8 during the Interrupt Period. At all other times, the host will ignore the level on Pin 8, and treat it as the data signal. The definition of the Interrupt Period is different for operations with single block and multiple block data transfers.

In the case of normal single data block transmissions, the Interrupt Period becomes active two clock cycles after the completion of a data packet. This Interrupt Period lasts until after the card receives the end bit of the next command that has a data block transfer associated with it.

For multiple block data transfers in 4-bit mode, there is only a limited period of time that the Interrupt Period can be active due to the limited period of data line availability between the multiple blocks of data. This requires a more strict definition of the Interrupt Period. For this case, the Interrupt Period is limited to two clock cycles. This begins two clocks after the end bit of the previous data block. During this 2-clock cycle interrupt period, if an interrupt is pending, the DATA1 line will be held low for one clock cycle with the last clock cycle pulling DATA1 high. On completion of the Interrupt Period, the card releases the DATA1 line into the high Z state. The uSDHC samples the DATA1 during the Interrupt Period when the IABG bit in the Protocol Control register is set.

Refer to SDIO Card Specification v1.10f for further information about the SDIO card interrupt.

26.5.6.3 Card Interrupt Handling

When the CINTIEN bit in the Interrupt Signal Enable Register is set to 0, the uSDHC clears the interrupt request to the Host System. The Host Driver should clear this bit before servicing the SDIO Interrupt and should set this bit again after all interrupt requests from the card are cleared to prevent inadvertent interrupts.

The SDIO Card Interrupt Status can be cleared by writing 1 to this bit. But as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. In 1-bit mode, the uSDHC will detect the SDIO Interrupt with or without the SD clock (to support wakeup). In 4-bit mode, the interrupt signal is sampled during the Interrupt Period, so there are some sample delays between the interrupt signal from the SDIO card and the interrupt to the Host System Interrupt Controller. When the
SDIO status has been set, and the Host Driver needs to service this interrupt, so the SDIO bit in the Interrupt Control Register of SDIO card will be cleared. This is required to clear the SDIO interrupt status latched in the uSDHC and to stop driving the interrupt signal to the System Interrupt Controller. The Host Driver must issue a CMD52 to clear the card interrupt. After completion of the card interrupt service, the SDIO Interrupt Status Enable bit is set to 1, and the uSDHC starts sampling the interrupt signal again.

See the figure below for an illustration of the SDIO card interrupt scheme and for the sequences of software and hardware events that take place during a card interrupt handling procedure.

**Figure 26-15. Card Interrupt Scheme and Card Interrupt Detection and Handling Procedure**
26.5.7 Card Insertion and Removal Detection

The uSDHC uses either the DATA3 pin or the CD_B pin to detect card insertion or removal. When there is no card on the MMC/SD bus, the DATA3 will be pulled to a low voltage level by default.

When any card is inserted to or removed from the socket, the uSDHC detects the logic value changes on the DATA3 pin and generates an interrupt. When the DATA3 pin is not used for card detection (for example, it is implemented in GPIO), the CD_B pin must be connected for card detection. Whether DATA3 is configured for card detection or not, the CD_B pin is always a reference for card detection. Whether the DATA3 pin or the CD_B pin is used to detect card insertion, the uSDHC will send an interrupt (if enabled) to inform the Host system that a card is inserted.

26.5.8 Power Management and Wake Up Events

When there is no operation between the uSDHC and the card through the SD bus, the user can completely disable the ipg_clk and ipg_perclk in the chip level clock control module to save power. When the user needs to use the uSDHC to communicate with the card, it can enable the clock and start the operation.

In some circumstances, when the clocks to the uSDHC are disabled, for instance, when the system is in low power mode, there are some events for which the user needs to enable the clock and handle the event. These events are called wakeup interrupts. The uSDHC can generate these interrupt even when there are no clocks enabled. The three interrupts which can be used as wake up events are:
1. Card Removal Interrupt
2. Card Insertion Interrupt
3. Interrupt from SDIO card

The uSDHC offers a power management feature. By clearing the clock enabled bits in the System Control Register, the clocks are gated in the low position to the uSDHC. For maximum power saving, the user can disable all the clocks to the uSDHC when there is no operation in progress.

These three wake up events (or wakeup interrupts) can also be used to wake up the system from low-power modes.

**NOTE**

To make the interrupt a wakeup event, when all the clocks to the uSDHC are disabled or when the whole system is in low power mode, the corresponding wake up enabled bit needs to be
set. Refer to Protocol Control (PROT_CTRL) for more information on the uSDHC Protocol Control register.

26.5.8.1 Setting Wake Up Events

For the uSDHC to respond to a wakeup event, the software must set the respective wakeup enable bit before the CPU enters sleep mode.

Before the software disables the host clock, it should ensure that all of the following conditions have been met:

- No Read or Write Transfer is active
- Data and Command lines are not active
- No interrupts are pending
- Internal data buffer is empty

26.5.9 MMC fast boot

The Embedded MultiMediaCard (eMMC4.3) specification adds a fast boot feature which requires hardware support. There are two types of fast boot mode, boot operation, and alternative boot operation in the eMMC4.3 specification. Each type also has with-acknowledge and without-acknowledge modes.

In boot operation mode, the master (MultiMediaCard host) can read boot data from the slave (MMC device) by keeping CMD line low after power-on, or sending CMD0 with argument + 0xFFFFFFFFFA (optional for slave), before issuing CMD1.

NOTE
For the eMMC4.3 card setting, please see the eMMC4.3 specification.

26.5.9.1 Boot operation

NOTE
For the purposes of this documentation, fast boot is called "normal fast boot mode".

If the CMD line is held LOW for 74 clock cycles and more after power-up before the first command is issued, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.
Within 1 second after the CMD line goes LOW, the slave starts to send the first boot data to the master on the DATA line(s). The master must keep the CMD line LOW to read all of the boot data.

If boot acknowledge is enabled, the slave has to send acknowledge pattern '010' to the master within 50ms after the CMD line goes LOW. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode with the CMD line HIGH.

Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

Figure 26-16. MultiMediaCard state diagram (normal boot mode)

26.5.9.2 Alternative boot operation

This boot function is optional for the device. If bit 0 in the extended CSD byte[228] is set to '1', the device supports the alternative boot operation.

After power-up, if the host issues CMD0 with the argument of 0xFFFFFFFFA after 74 clock cycles, before CMD1 is issued or the CMD line goes low, the slave recognizes that boot mode is being initiated and starts preparing boot data internally.

Within 1 second after CMD0 with the argument of 0xFFFFFFFFA is issued, the slave starts to send the first boot data to the master on the DATA line(s).

If boot acknowledge is enabled, the slave has to send the acknowledge pattern '010' to the master within 50ms after the CMD0 with the argument of 0xFFFFFFFFA is received. If boot acknowledge is disabled, the slave will not send out acknowledge pattern '010'.

The master can terminate boot mode by issuing CMD0 (Reset).
Boot operation will be terminated when all contents of the enabled boot data are sent to the master. After boot operation is executed, the slave shall be ready for CMD1 operation and the master needs to start a normal MMC initialization sequence by sending CMD1.

NOTE 1. CMD0 with argument 0xFFFFFFFFFA

Figure 26-17. MultiMediaCard state diagram (alternative boot mode)

26.6 Initialization/Application of uSDHC

All communication between the system and cards are controlled by the host. The host sends commands of two types: broadcast and addressed (point-to-point).

Broadcast commands are intended for all cards, such as GO_IDLE_STATE, SEND_OP_COND, ALL_SEND_CID. In Broadcast mode, all cards are in the open-drain mode to avoid bus contention. Refer to Commands for MMC/SD/SDIO for the commands of bc and bcr categories.

After the Broadcast command CMD3 is issued, the cards enter standby mode. Addressed type commands are used from this point. In this mode, the CMD/DATA I/O pads will turn to push-pull mode, to have the driving capability for maximum frequency operation. Refer to Commands for MMC/SD/SDIO for the commands of ac and adtc categories.
26.6.1 Command Send & Response Receive Basic Operation

Assuming the data type WORD is an unsigned 32-bit integer, the below flow is a guideline for sending a command to the card(s):

```c
send_command(cmd_index, cmd_arg, other requirements)
{
    WORD wCmd; // 32-bit integer to make up the data to write into Transfer Type register, it is recommended to implement in a bit-field manner
    wCmd = (<cmd_index> & 0x3f) >> 24; // set the first 8 bits as '00'+<cmd_index>
    set CMDTYP, DPSEL, CICEN, CCCEN, RSTTYP, DTDSEL according to the command index;
    if (internal DMA is used) wCmd |= 0x1;
    if (multi-block transfer) {
        set MSBSEL bit;
        if (finite block number) {
            set BCEN bit;
            if (auto12 command is to use) set AC12EN bit;
        }
    }
    write_reg(CMDARG, <cmd_arg>); // configure the command argument
    write_reg(XFERTYP, wCmd); // set Transfer Type register as wCmd value to issue the command
}
wait_for_response(cmd_index)
{
    while (CC bit in IRQ Status register is not set); // wait until Command Complete bit is set
    read IRQ Status register and check if any error bits about Command are set
    if (any error bits are set) report error;
    write 1 to clear CC bit and all Command Error bits;
}
```

For the sake of simplicity, the function wait_for_response is implemented here by means of polling. For an effective and formal way, the response is usually checked after the Command Complete Interrupt is received. When doing this, make sure the corresponding interrupt status bits are enabled.

For some scenarios, the response time-out is expected. For instance, after all cards respond to CMD3 and go to the Standby State, no response to the Host when CMD2 is sent. The Host Driver will deal with "fake" errors like this with caution.

26.6.2 Card Identification Mode

When a card is inserted to the socket or the card was reset by the host, the host needs to validate the operation voltage range, identify the cards, request the cards to publish the Relative Card Address (RCA) or to set the RCA for the MMC cards.

26.6.2.1 Card Detect

See the figure below for a flow diagram showing the detection of MMC, SD and SDIO cards using the uSDHC.
Enable card detection irq

Wait for uSDHC interrupt

Check CINS bit

Yes cards present

Clear CINSIEN to disable card detection irq

Voltage validation

No cards present

Figure 26-18. Flow Diagram for Card Detection

Here is the card detect sequence:

- Set the CINSIEN bit to enable card detection interrupt
- When an interrupt from the uSDHC is received, check the CINS bit in the Interrupt Status register to see if it was caused by card insertion
- Clear the CINSIEN bit to disable the card detection interrupt and ignore all card insertion interrupts afterwards

26.6.2.2 Reset

The host consists of three types of resets:

- Hardware reset (Card and Host) which is driven by POR (Power On Reset)
• Software reset (Host Only) is initiated by the write operation on the RSTD, RSTC, or RSTA bits of the System Control register to reset the data part, command part, or all parts of the Host Controller, respectively
• Card reset (Card Only). The command, "Go_Idle_State" (CMD0), is the software reset command for all types of MMC cards, SD Memory cards. This command sets each card into the Idle State regardless of the current card state. For an SD I/O Card, CMD52 is used to write an I/O reset in the CCCR. The cards are initialized with a default relative card address (RCA=0x0000) and with a default driver stage register setting (lowest speed, highest driving current capability).

After the card is reset, the host needs to validate the voltage range of the card. See the figure below for the software flow to reset both the uSDHC and the card.

Figure 26-19. Flow Chart for Reset of the uSDHC and SD I/O Card

```c
software_reset()
{
    set_bit(SYSCTRL, RSTA); // software reset the Host
    set DTOCV and SDCLKFS bit fields to get the CLK of frequency around 400kHz
    configure IO pad to set the power voltage of external card to around 3.0V
    poll bits CIHB and CDIHB bits of PRSSTAT to wait both bits are cleared
    set_bit(SYSCTRL, INTIA); // send 80 clock ticks for card to power up
    send_command(CMD_GO_IDLE_STATE, <other parameters>); // reset the card with CMD0
    or send_command(CMD_IO_RW_DIRECT, <other parameters>);
}
```

### 26.6.2.3 Voltage Validation

All cards should be able to establish communication with the host using any operation voltage in the maximum allowed voltage range specified in the card specification. However, the supported minimum and maximum values for Vdd are defined in the Operation Conditions Register (OCR) and may not cover the whole range.
Cards that store the CID and CSD data in the preload memory are only able to communicate this information under data transfer Vdd conditions. This means if the host and card have non-common Vdd ranges, the card will not be able to complete the identification cycle, nor will it be able to send CSD data.

Therefore, a special command Send_Op_Con (CMD1 for MMC), SD_Send_Op_Con (ACMD41 for SD Memory) and IO_Send_Op_Con (CMD5 for SD I/O) is used. The voltage validation procedure is designed to provide a mechanism to identify and reject cards which do not match the Vdd range(s) desired by the host. This is accomplished by the host sending the desired Vdd voltage window as the operand of this command. Cards that can't perform the data transfer in the specified range must discard themselves from further bus operations and go into the Inactive State. By omitting the voltage range in the command, the host can query each card and determine the common voltage range before sending out-of-range cards into the Inactive State. This query should be used if the host is able to select a common voltage range or if a notification shall be sent to the system when a non-usable card in the stack is detected.

The following steps show how to perform voltage validation when a card is inserted:

```c
voltage_validation(voltage_range_argument)
{
    label the card as UNKNOWN;
    send_command(IO_SEND_OP_COND, 0x0, <other parameters are omitted>); // CMD5, check SDIO operation voltage, command argument is zero
    if (RESP_TIMEOUT != wait_for_response(IO_SEND_OP_COND)) { // SDIO command is accepted
        if (0 < number of IO functions) {
            label the card as SDIO;
            IORDY = 0;
            while (!IORDY in IO OCR response)) { // set voltage range for each IO function
                send_command(IO_SEND_OP_COND, <voltage range>, <other parameter>);
                wait_for_response(IO_SEND_OP_COND);
            } // end of while ...
        } // end of if (0 < ...
        if (memory part is present inside SDIO card) Label the card as SDCombo; // this is an SD-Combo card
    } // end of if (RESP_TIMEOUT ...
    if (the card is labelled as SDIO card) return; // card type is identified and voltage range is set, so exit the function;
    send_command(APP_CMD, 0x0, <other parameters are omitted>); // CMD55, Application specific CMD prefix
    if (no error calling wait_for_response(APP_CMD, <...>) { // CMD55 is accepted
        send_command(SD_APP_OP_COND, <voltage range>, <...>); // ACMD41, to set voltage range
        for memory part or SD card
        wait_for_response(SD_APP_OP_COND); // voltage range is set
        if (card type is UNKNOWN) label the card as SD; return; //
    } // end of if (no error ...
    else if (errors other than time-out occur) { // command/response pair is corrupted deal with it by program specific manner;
} // of else if (response time-out
else { // CMD55 is refuse, it must be MMC card if (card is already labelled as SDCombo)
    change label
```
re-label the card as SDIO;
    ignore the error or report it;
    return; // card is identified as SDIO card
} // of if {card is ...
send_command(SEND_OP_COND, <voltage range>, <...>);
if (RESP_TIMEOUT == wait_for_response(SEND_OP_COND)) { // CMD1 is not accepted,
either
    label the card as UNKNOWN;
    return;
} // of if {RESP_TIMEOUT ...
} // of else

26.6.2.4 Card Registry

Card registry for the MMC and SD/SDIO/SD Combo cards are different. For the SD Card, the Identification process starts at a clock rate lower than 400 kHz and the power voltage higher than 2.7 V (as defined by the Card spec). At this time, the CMD line output drives are push-pull drivers instead of open-drain. After the bus is activated, the host will request the card to send their valid operation conditions.

The response to ACMD41 is the operation condition register of the card. The same command shall be send to all of the new cards in the system. Incompatible cards are put into the Inactive State. The host then issues the command, All_Send_CID (CMD2), to each card to get its unique card identification (CID) number. Cards that are currently unidentified (in the Ready State), send their CID number as the response. After the CID is sent by the card, the card goes into the Identification State.

The host then issues Send_Relative_Addr (CMD3), requesting the card to publish a new relative card address (RCA) that is shorter than the CID. This RCA will be used to address the card for future data transfer operations. Once the RCA is received, the card changes its state to the Standby State. At this point, if the host wants the card to have an alternative RCA number, it may ask the card to publish a new number by sending another Send_Relative_Addr command to the card. The last published RCA is the actual RCA of the card.

The host repeats the identification process with CMD2 and CMD3 for each card in the system until the last CMD2 gets no response from any of the cards in system.

For MMC operation, the host starts the card identification process in open-drain mode with the identification clock rate lower than 400 kHz and the power voltage higher than 2.7 V. The open drain driver stages on the CMD line allow parallel card operation during card identification. After the bus is activated the host will request the cards to send their valid operation conditions (CMD1). The response to CMD1 is the "wired OR" operation on the condition restrictions of all cards in the system. Incompatible cards are sent into the Inactive State. The host then issues the broadcast command All_Send_CID (CMD2), asking all cards for their unique card identification (CID) number. All unidentified cards
(the cards in Ready State) simultaneously start sending their CID numbers serially, while bit-wise monitoring their outgoing bit stream. Those cards, whose outgoing CID bits do not match the corresponding bits on the command line in any one of the bit periods, stop sending their CID immediately and must wait for the next identification cycle. Since the CID is unique for each card, only one card can be successfully send its full CID to the host. This card then goes into the Identification State. Thereafter, the host issues Set_Relative_Addr (CMD3) to assign to the card a relative card address (RCA). Once the RCA is received the card state changes to the Stand-by State, and the card does not react in further identification cycles, and its output driver switches from open-drain to push-pull. The host repeats the process, mainly CMD2 and CMD3, until the host receives a timeout condition to recognize the completion of the identification process.

For operation as MMC cards:

```c
void card_registry()
{
    do { // decide RCA for each card until response time-out
        if (card is labelled as SDCombo or SDIO) { // for SDIO card like device
            send_command(SET_RELATIVE_ADDR, 0x00, <...>); // ask SDIO card to publish its RCA
            retrieve RCA from response;
        } // end if (card is labelled as SDCombo ...
        else if (card is labelled as SD) { // for SD card
            send_command(ALL_SEND_CID, <...>);
            if (RESP_TIMEOUT == wait_for_response(ALL_SEND_CID)) break;
            send_command(SET_RELATIVE_ADDR, <...>);
            retrieve RCA from response;
        } // else if (card is labelled as SD ...
        else if (card is labelled as MMC) {
            send_command(ALL_SEND_CID, <...>);
            rca = 0x1; // arbitrarily set RCA, 1 here for example
            send_command(SET_RELATIVE_ADDR, 0x1 << 16, <...>); // send RCA at upper 16 bits
        } // end of else if (card is labelled as MMC ...
    } while (response is not time-out);
}
```

### 26.6.3 Card Access

Information about Block Write, Block Read, Suspense Resume, ADMA Usage, Transfer Error, and Card Interrupt are detailed in the sections below.

#### 26.6.3.1 Block Write

Information on Normal Write, DDR Write, and Write with Pause are detailed in the sections below.
26.6.3.1.1 Normal Write

During a block write (CMD24 - 27, CMD60, CMD61), one or more blocks of data are transferred from the host to the card with a CRC appended to the end of each block by the host. If the CRC fails, the card shall indicate the failure on the DATA line. The transferred data will be discarded and not written, and all further transmitted blocks (in multiple block write mode) will be ignored.

If the host uses partial blocks whose accumulated length is not block aligned and block misalignment is not allowed (CSD parameter WRITE_BLK_MISALIGN is not set), the card detects the block misalignment error and aborts the programming before the beginning of the first misaligned block. The card sets the ADDRESS_ERROR error bit in the status register, and while ignoring all further data transfer, waits in the Receive-data-State for a stop command. The write operation is also aborted if the host tries to write over a write protected area.

For MMC and SD cards, programming of the CID and CSD registers does not require a previous block length setting. The transferred data is also CRC protected. If a part of the CSD or CID register is stored in ROM, then this unchangeable part must match the corresponding part of the receive buffer. If this match fails, then the card will report an error and not change any register contents.

For all types of cards, some may require long and unpredictable periods of time to write a block of data. After receiving a block of data and completing the CRC check, the card will begin writing and hold the DATA line low if its write buffer is full and unable to accept new data from a new WRITE_BLOCK command. The host may poll the status of the card with a SEND_STATUS command (CMD13) or other means for SDIO cards at any time, and the card will respond with its status. The responded status indicates whether the card can accept new data or whether the write process is still in progress. The host may deselect the card by issuing a CMD7 (to select a different card) to place the card into the Standby State and release the DATA line without interrupting the write operation. When re-selecting the card, it will reactivate the busy indication by pulling DATA to low if the programming is still in progress and the write buffer is unavailable.

The software flow to write to a card incorporates the internal DMA and the write operation is a multi-block write with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to write to a card is described below:

1. Check the card status, wait until the card is ready for data.
2. Set the card block length/size:
For SD/MMC cards, use SET_BLOCKLEN (CMD16)
For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT (CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)

3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
7. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

26.6.3.1.2 DDR Write

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described as below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit /8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

26.6.3.1.3 Write with Pause

The write operation can be paused during the transfer. Instead of stopping the CLK at any time to pause all the operations, which is also inaccessible to the Host Driver, the Driver can set the Stop At Block Gap Request(SABGREQ) bit in the Protocol Control register to pause the transfer between the data blocks. As there is no time-out condition in a write operation during the data blocks, a write to all types of cards can be paused in this way, and if the DATA0 line is not required to de-assert to release the busy state, no suspend command is needed.
Like in the flow described in **Normal Write**, the write with pause is shown with the same kind of write operation:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16)
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
6. Set the SABGREQ bit.
7. Wait for the Transfer Complete interrupt.
8. Clear the SABGREQ bit.
9. Check the status bit to see if a write CRC error occurred.
10. Set the CREQ bit to continue the write operation.
12. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

The number of blocks left during the data transfer is accessible by reading the contents of the BLKCNT field in the Block Attribute register. As the data transfer and the setting of the SABGREQ bit are concurrent, and the delay of register read and the register setting, the actual number of blocks left may not be exactly the value read earlier. The Driver shall read the value of BLKCNT after the transfer is paused and the Transfer Complete interrupt is received.

It is also possible the last block has begun when the Stop At Block Gap Request is sent to the buffer. In this case, the next block gap is actually the end of the transfer. These types of requests are ignored and the Driver should treat this as a non-pause transfer and deal with it as a common write operation.

When the write operation is paused, the data transfer inside the Host System is not stopped, and the transfer is active until the data buffer is full. Because of this (if not needed), it is recommended to avoid using the Suspend Command for the SDIO card. This is because when such a command is sent, the uSDHC thinks the System will switch to another function on the SDIO card, and flush the data buffer. The uSDHC takes the Resume Command as a normal command with data transfer, and it is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to
send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set as well as the AC12EN bit. However, the uSDHC will automatically send a CMD12 to mark the end of the multi-block transfer.

### 26.6.3.2 Block Read

Information about Normal Read, DDR Read, Read with Pause, and DLL (Delay Line) in Read Path are detailed in the sections below.

#### 26.6.3.2.1 Normal Read

For block reads, the basic unit of data transfer is a block whose maximum size is stored in areas defined by the corresponding card specification. A CRC is appended to the end of each block, ensuring data transfer integrity. The CMD17, CMD18, CMD53, CMD60, CMD61, and so on, can initiate a block read. After completing the transfer, the card returns to the Transfer State. For multi blocks read, data blocks will be continuously transferred until a stop command is issued.

The software flow to read from a card incorporates the internal DMA and the read operation is a multi-block read with the Auto CMD12 enabled. For the other methods (CPU polling status) with different transfer methods, the internal DMA parts should be removed and the alternative steps should be straightforward.

The software flow to read from a card is described below:

1. Check the card status, wait until card is ready for data.
2. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16)
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
3. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
4. Set the uSDHC number block register (NOB), nob is 5 (for instance).
5. Disable the buffer read ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
7. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.
26.6.3.2.2 DDR Read

uSDHC supports dual data rate mode.

The software flow to write to a card in ddr mode is described below:

1. Check the card status, wait until the card is ready for data.
2. For eMMC4.4 card, block length only can be set to 512byte.
3. Set the uSDHC number block register (NOB), nob is 5 (for instance).
4. Set eMMC4.4 card to high speed mode, use SWITCH(CMD6).
5. Set eMMC4.4 card bus with (4-bit/8-bit ddr mode), use SWITCH(CMD6).
6. Disable the buffer write ready interrupt, configure the DMA settings and enable the uSDHC DMA when sending the command with data transfer. The DDR_EN bit should be set. The AC12EN bit should also be set.
7. Wait for the Transfer Complete interrupt.
8. Check the status bit to see if a write CRC error occurred, or some another error, that occurred during the auto12 command sending and response receiving.

26.6.3.2.3 Read with Pause

The read operation is not generally able to pause. Only the SDIO card (and SDCombo card working under I/O mode) supporting the Read Wait feature can pause during the read operation. If the SDIO card supports Read Wait (SRW bit in CCCR register is 1), the Driver can set the SABGREQ bit in the Protocol Control register to pause the transfer between the data blocks.

Before setting the SABGREQ bit, make sure the RWCTL bit in the Protocol Control register is set, otherwise the uSDHC will not assert the Read Wait signal during the block gap and data corruption occurs. It is recommended to set the RWCTL bit once the Read Wait capability of the SDIO card is recognized.

Like in the flow described in Normal Read, the read with pause is shown with the same kind of read operation:

1. Check the SRW bit in the CCR register on the SDIO card to confirm the card supports Read Wait.
2. Set the RWCTL bit.
3. Check the card status and wait until the card is ready for data.
4. Set the card block length/size:
   - For SD/MMC, use SET_BLOCKLEN (CMD16)
   - For SDIO cards or the I/O portion of SDCombo cards, use IO_RW_DIRECT(CMD52) to set the I/O Block Size bit field in the CCCR register (for function 0) or FBR register (for functions 1~7)
5. Set the uSDHC block length register to be the same as the block length set for the card in Step 2.
6. Set the uSDHC number block register (NOB), nob is 5 (for instance).
7. Disable the buffer read ready interrupt, configure the DMA setting and enable the uSDHC DMA when sending the command with data transfer. The AC12EN bit should also be set.
8. Set the SABGREQ bit.
10. Clear the SABGREQ bit.
11. Check the status bit to see if read CRC error occurred.
12. Set the CREQ bit to continue the read operation.
14. Check the status bit to see if a read CRC error occurred, or some another error, occurred during the auto12 command sending and response receiving.

Like the write operation, it is possible to meet the ending block of the transfer when paused. In this case, the uSDHC will ignore the Stop At Block Gap Request and treat it as a command read operation.

Unlike the write operation, there is no remaining data inside the buffer when the transfer is paused. All data received before the pause will be transferred to the Host System. No matter if the Suspend Command is sent or not, the internal data buffer is not flushed.

If the Suspend Command is sent and the transfer is later resumed by means of a Resume Command, the uSDHC takes the command as a normal one accompanied with data transfer. It is left for the Driver to set all the relevant registers before the transfer is resumed. If there is only one block to send when the transfer is resumed, the MSBSEL and BCEN bits of the Transfer Type register are set, as well as the AC12EN bit.

However, the uSDHC will automatically send the CMD12 to mark the end of multi-block transfer.

### 26.6.3.2.4 DLL (Delay Line) in Read Path

The DLL (Delay Line) is newly added to assist in sampling read data. The DLL provides the ability to programatically select a quantized delay (in fractions of the clock period) regardless of on-chip variations such as process, voltage and temperature (PVT).

The reasons why the DLL is needed for uSDHC are 1.) the path of read data traveling from card to host varies. 2.) in SD/MMC DDR mode the minimum input setup and hold time are both at 2.5 ns. The data sampling window is so small that the delay of loopback clock needs to be accurate and consistent regardless of PVT. The DLL takes the divided card_clk as the reference clock and loopback clock as the input clock. It then generates a delayed version of the input clock according to the programmed target delay.
The DLL can be disabled or bypassed, and it can also be manually set for a fixed delay in override mode. The override value set is the number of delay cells. In override mode, there is no need to set the DLL_enable. Another DLL mode is target value mode. In this mode, the DLL will automatically adjust the number of delay cells according to target value set by user and PVT changes. Be aware that target value is in units of 1/32 of the clock reference period. If the card_clk is 100Mhz, then the reference clock period is 10ns, setting target value of 16 means 5ns = (16/32)*10ns. Software can disable automatic update by setting dll_gate_update bit.

Since the user may change the frequency of the card_clk from time to time by changing SDCLKFS[7:0]/DVS[3:0], the software must adjust the delay value to ensure it works correctly when the reference clock (card_clk) is changed. The following is the correct flow, which should be ignored if DLL_CTRL_ENABLE is not set.

Step 1: Set DLL_CTRL_RESET bit

Step 2: Configure the SDCLKFS[7:0] and DVS[3:0]

Step 3: Wait until SDSTB is asserted

Step 4: clear DLL_CTRL_RESET bit

Step 5: Wait until both DLL_STS_SLV_LOCK and DLL_STS_REF_LOCK are asserted

Step 6: set DLL_CTRL_SLV_FORCE_UPD

Step 7: clear DLL_CTRL_SLV_FORCE_UPD

NOTE

Software should make sure the DLL_CTRL_SLV_FORCE_UPD is lasted for at least one card_clk. So software may need to add some delay between Step6 and Step7.
26.6.3.3 Suspend Resume

The uSDHC supports the Suspend Resume operations of SDIO cards, although slightly differently than the suggested implementation of Suspend in the SDIO card specification.

26.6.3.3.1 Suspend

After setting the SABGREQ bit, the Host Driver may send a Suspend command to switch to another function of the SDIO card. The uSDHC does not monitor the content of the response, so it doesn't know if the Suspend command succeeded or not. Accordingly, it doesn't de-assert Read Wait for read pause. To solve this problem, the Driver shall not mark the Suspend command as a "Suspend", (i.e. setting the CMDTYP bits to 01). Instead, the Driver shall send this command as if it were a normal command, and only
when the command succeeds, and the BS bit is set in the response, can the Driver send another command marked as "Suspend" to inform the uSDHC that the current transfer is suspended. As shown in the following sequence for Suspend operation:

1. Set the SABREQ bit to pause the current data transfer at block gap.
2. After the BGE bit is set, send the Suspend command to suspend the active function. The CMDTYP bit field must be 2'b00.
3. Check the BS bit of the CCCR in the response. If it is 1, repeat this step until the BS bit is cleared or abandon the suspend operation according to the Driver strategy.
4. Send another normal I/O command to the suspended function. The CMDTYP of this command must be 2'b01, so the uSDHC can detect this special setting and be informed that the paused operation has successfully suspended. If the paused transfer is a read operation, the uSDHC stops driving DATA2 and goes to the idle state.
5. Save the context registers in the system memory for later use, including the DMA System Address Register (for internal DMA operation), and the Block Attribute Register.
6. Begin operation for another function on the SDIO card.

26.6.3.3.2 Resume

To resume the data transfer, a Resume command shall be issued:

1. To resume the suspended function, restore the context register with the saved value in step #5 of the Suspend operation above.
2. Send the Resume command. In the Transfer Type register, all bit fields are set to the value as if this were another ordinary data transfer, instead of a transfer resume (except the CMDTYP is set to 2'b10).
3. If the Resume command has responded, the data transfer will be resumed.

26.6.3.4 ADMA Usage

To use the ADMA in a data transfer, the Host Driver must prepare the correct descriptor chain prior to sending the read/write command.

The steps to prepare the correct descriptor chain are:

1. Create a descriptor to set the data length that the current descriptor group is about to transfer. The data length should be even numbers of the block size.
2. Create another descriptor to transfer the data from the address setting in this descriptor. The data address must be at a page boundary (4kB address aligned).
3. If necessary, create a Link descriptor containing the address of the next descriptor. The descriptor group is created in steps 1 ~ 3.
4. Repeat steps 1 ~ 3 until all descriptors are created.
5. In the last descriptor, set the End flag to 1 and make sure the total length of all
descriptors match the product of the block size and block number configured in the
Block Attribute Register.
6. Set the ADMA System Address Register to the address of the first descriptor and set
the DMAS field in the Protocol Control Register to 01 to select the ADMA.
7. Issue a write or read command with the DMAEN bit set to 1 in the Transfer Type
Register.

Steps 1 ~ 5 are independent of step 6, so step 6 can finish before steps 1 ~ 5. Regarding
the descriptor configuration, it is recommended not to use the Link descriptor as it
requires extra system memory access.

26.6.3.5 Transfer Error

Information about CRC, Internal DMA, Transfer ADMA, and Auto CMD12 Errors are
detailed in the sections below.

26.6.3.5.1 CRC Error

It is possible at the end of a block transfer, that a write CRC status error or read CRC
error occurs. For this type of error the latest block received shall be discarded. This is
because the integrity of the data block is not guaranteed. It is recommended to discard the
following data blocks and re-transfer the block from the corrupted one.

For a multi-block transfer, the Host Driver shall issue a CMD12 to abort the current
process and start the transfer by a new data command. In this scenario, even when the
AC12EN and BCEND bits are set, the uSDHC does not automatically send a CMD12
because the last block is not transferred. On the other hand, if it is within the last block
that the CRC error occurs, an Auto CMD12 will be sent by the uSDHC. In this case, the
Driver shall re-send or re-obtain the last block with a single block transfer.

26.6.3.5.2 Internal DMA Error

During the data transfer with internal Simple DMA, if the DMA engine encounters some
error on the AHB bus, the DMA operation is aborted and DMA Error interrupt is sent to
the Host System. When acknowledged by such an interrupt, the Driver shall calculate the
start address of data block in which the error occurs.

The start address can be calculated by either:

1. Reading the DMA System Address register. The error occurs during the previous
   burst. Taking the block size, the previous burst length and the start address of the
next burst transfer into account, it is straightforward to obtain the start address of the corrupted block.

2. Reading the BLKCNT field of the Block Attribute register. By the number of blocks left, the total number to transfer, the start address of transfer, and the size of each block, the start address of corrupted block can be determined. When the BCEN bit is not set, the contents of the Block Attribute register does not change, so this method does not work.

When a DMA error occurs, it is recommended to abort the current transfer by means of a CMD12 (for multi block transfer), apply a reset for data, and re-start the transfer from the corrupted block to recover from the error.

### 26.6.3.5.3 Transfer ADMA Error

There are 3 kinds of possible ADMA errors. The AHB transfer, invalid descriptor, and data-length mismatch errors. Whenever these errors occur, the DMA transfer stops and the corresponding error status bit is set.

For acknowledging the status, the Host Driver should recover the error as shown below and re-transfer from the place of interruption.

1. AHB transfer error: Such errors may occur during data transfer or descriptor fetch. For either scenario, it is recommended to retrieve the transfer context, reset for the data part and re-transfer the block that was corrupted, or the next block if no block is corrupted.
2. Invalid descriptor error: For such errors, it is recommended to retrieve the transfer context, reset for the data part and re-create the descriptor chain from the invalid descriptor and issue a new transfer. As the data to transfer now may be less than the previous setting, the data length configured in the new descriptor chain should match the new value.
3. Data-length mismatch error: It is similar to recover from this error. The Host Driver polls relating registers to retrieve the transfer context, apply a reset for the data part, configure a new descriptor chain, and make another transfer if there is data left. Like the previous scenario of the invalid descriptor error, the data length must match the new transfer.

### 26.6.3.5.4 Auto CMD12 Error

After the last block of the multi block transfer is sent or received, and the AC12EN bit is set when the data transfer is initiated by the data command, the uSDHC automatically sends a CMD12 to the card to stop the transfer.
When errors with this command occur, it is recommended to the Driver to deal with the situations in the following manner:

1. Auto CMD12 response time-out. It is not certain whether the command is accepted by the card or not. The Driver should clear the Auto CMD12 error status bits and re-send the CMD12 until it is accepted by the card.
2. Auto CMD12 response CRC error. Since card responds to the CMD12, the card will abort the transfer. The Driver may ignore the error and clear the error status bit.
3. Auto CMD12 conflict error or not sent. The command is not sent, so the Driver shall send a CMD12 manually.

### 26.6.3.6 Card Interrupt

The external cards can inform the Host Controller by means of some special signals. For the SDIO card, it can be the low level on the DATA1 line during some special period. The uSDHC only monitors the DATA1 line and supports the SDIO interrupt.

When the SDIO interrupt is captured by the uSDHC, and the Host System is informed by the uSDHC asserting the uSDHC interrupt line, the interrupt service from the Host Driver is called.

As the interrupt source is controlled by the external card, the interrupt from the SDIO card must be serviced before the CINT bit is cleared by written. Refer to Card Interrupt Handling for the card interrupt handling flow.

### 26.6.4 Switch Function

A switch command shall be issued by the Host Driver to enable new features added to the SD/MMC spec. SD/MMC cards can transfer data at bus widths other than 1-bit. Different speed mode are also defined. To enable these features, a switch command shall be issued by the Host Driver.

For SDIO cards, the high speed mode/DDR50/SDR50/SDR104 are enabled by writing the EHS bit in the CCCR register after the SHS bit is confirmed. For SD cards, the high speed mode/DDR50/SDR50/SDR104 are queried and enabled by a CMD6 (with the mnemonic symbol as SWITCH_FUNC). For MMC cards, the high speed mode/HS200 are queried by a CMD8 and enabled by a CMD6 (with the mnemonic symbol as SWITCH).

The SDR4-bit, SDR8-bit, DDR4-bit and DDR8-bit width of the MMC is also enabled by the SWITCH command, but with a different argument.
These new functions can also be disabled by a software reset. For SDIO cards it can be done by setting the RES bit in the CCCR register. For other cards, it can be accomplished by issuing a CMD0. This method of restoring to the normal mode is not recommended because a complete identification process is needed before the card is ready for data transfer.

For the sake of simplicity, the following pseudocode examples do not show current capability check, which is recommended in the function switch process.

### 26.6.4.1 Query, Enable and Disable SDIO High Speed Mode

```
enable_sdio_high_speed_mode(void)
{
    send CMD52 to query bit SHS at address 0x13;
    if (SHS bit is '0') report the SDIO card does not support high speed mode and return;
    send CMD52 to set bit EHS at address 0x13 and read after write to confirm EHS bit is set;
    change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk of around 50MHz;
    (data transactions like normal peers)
}
disable_sdio_high_speed_mode(void)
{
    send CMD52 to clear bit EHS at address 0x13 and read after write to confirm EHS bit is cleared;
    change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk of the desired value below 25MHz;
    (data transactions like normal peers)
}
```

### 26.6.4.2 Query, Enable and Disable SD High Speed Mode/SDR50/SDF104/DDR50

```
enable_sd_speed_mode(void)
{
    set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
    send CMD6, with argument 0xFFFFFx and read 64 bytes of data accompanying the R1 response;
    (high speed mode,x=1; SDR50,x=2; SDR104,x=3; DDR50,x=4;)
    wait data transfer done bit is set;
    check if the bit x of received 512 bits is set;
    if (bit 401 is '0') report the SD card does not support high speed mode and return;
    if (bit 402 is '0') report the SD card does not support SDR50 mode and return;
    if (bit 403 is '0') report the SD card does not support SDR104 mode and return;
    if (bit 404 is '0') report the SD card does not support DDR50 mode and return;
    send CMD6, with argument 0x80FFFFFx and read 64 bytes of data accompanying the R1 response;
    (high speed mode,x=1; SDR50,x=2; SDR104 x=3; DDR50 x=4;)
    check if the bit field 379~376 is 0xF;
    if (the bit field is 0xF) report the function switch failed and return;
    change clock divisor value or configure the system clock feeding into uSDHC to generate the card_clk of around 50MHz for high speed mode, 100Mhz for SDR50, 200Mhz for SDR104, 50Mhz for DDR50;
    (data transactions like normal peers)
}
disable_sd_speed_mode(void)
{
    set BLKCNT field to 1 (block), set BLKSIZE field to 64 (bytes);
    send CMD6, with argument 0x80FFFFF0 and read 64 bytes of data accompanying the R1 response;
    check if the bit field 379~376 is 0xF;
```
if (the bit field is 0xF) report the function switch failed and return;
change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 25MHz;
(data transactions like normal peers)

26.6.4.3 Query, Enable and Disable MMC High Speed Mode

enable_mmc_high_speed_mode(void)
{
    send CMD9 to get CSD value of MMC;
    check if the value of SPEC_VER field is 4 or above;
    if (SPEC_VER value is less than 4) report the MMC does not support high speed mode and
    return;
    set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
    send CMD8 to get EXT_CSD value of MMC;
    extract the value of CARD_TYPE field to check the 'high speed mode' in this MMC is 26MHz or
    52MHz;
    send CMD6 with argument 0x1B90100;
    send CMD13 to wait card ready (busy line released);
    send CMD8 to get EXT_CSD value of MMC;
    check if HS_TIMING byte (byte number 185) is 1;
    if (HS_TIMING is not 1) report MMC switching to high speed mode failed and return;
    change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of around 26MHz or 52MHz according to the CARD_TYPE;
    (data transactions like normal peers)
}
disable_mmc_high_speed_mode(void)
{
    send CMD6 with argument 0x2B90100;
    set BLKCNT field to 1 (block), set BLKSIZE field to 512 (bytes);
    send CMD8 to get EXT_CSD value of MMC;
    check if HS_TIMING byte (byte number 185) is 0;
    if (HS_TIMING is not 0) report the function switch failed and return;
    change clock divisor value or configure the system clock feeding into uSDHC to generate the
card_clk of the desired value below 20MHz;
    (data transactions like normal peers)
}

26.6.4.4 Set MMC Bus Width

change_mmc_bus_width(void)
{
    send CMD9 to get CSD value of MMC;
    check if the value of SPEC_VER field is 4 or above;
    if (SPEC_VER value is less than 4) report the MMC does not support multiple bit width and
    return;
    send CMD6 with argument 0x3B70x00; (8-bit(dual data rate), x=6; 4-bit(dual data rate), x=5; 8-
    bit, x=2; 4-bit, x=1; 1-bit, x=0)
    send CMD13 to wait card ready (busy line released);
    (data transactions like normal peers)
}

26.6.5 ADMA Operation

Code for ADMA1 Operation and ADMA2 Operation can be found here.
26.6.5.1 ADMA1 Operation

Set_adma1_descriptor
{
    if (to start data transfer) {
        // Make sure the address is 4KB align.
        Set 'Set' type descriptor;
        {
            Set Act bits to 01;
            Set [31:12] bits data length (byte unit);
        }
        Set 'Tran' type descriptor;
        {
            Set Act bits to 10;
            Set [31:12] bits address (4KB align);
        }
    } else if (to fetch descriptor at non-continuous address) {
        Set Act bits to 11;
        Set [31:12] bits the next descriptor address (4KB aligned);
    } else { // other types of descriptor
        Set Act bits accordingly
    }
    if (this descriptor is the last one) {
        Set End bit to 1;
    }
    if (to generate interrupt for this descriptor) {
        Set Int bit to 1;
    }
    Set Valid bit to 1;
}

26.6.5.2 ADMA2 Operation

Set_adma2_descriptor
{
    if (to start data transfer) {
        // Make sure the address is a 32-bit boundary (lower 2-bit are always '00').
        Set higher 32-bit of descriptor for this data transfer initial address;
        Set [31:16] bits data length (byte unit);
        Set Act bits to '10';
    } else if (to fetch descriptor at non-continuous address) {
        Set Act bits to '11';
        // Make sure the address is 32-bit boundary (lower 2-bit are always set to '00').
        Set higher 32-bit of descriptor for the next descriptor address;
    } else { // other types of descriptor
        Set Act bits accordingly
    }
    if (this descriptor is the last one) {
        Set 'End' bit '1';
    }
    if (to generate interrupt for this descriptor) {
        Set 'Int' bit '1';
    }
    Set the 'Valid' bit to '1';
}
26.6.6 Fast Boot Operation

26.6.6.1 Normal fast boot flow
1. Software must configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software must configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 0 (normal fast boot), and bit 4 to select the ack mode or not. If the data will be sent through DMA mode, the software should configure bit 7 to enable the automatic stop at block gap feature, and configure bit 3-bit 0 to select the ack timeout value according to the SD CLK frequency.
3. Software then needs to configure the Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software must configure the Protocol control register to set DTW (data transfer width). If in DDR fast boot mode, DTW only can be configured to 4-bit/8-bit dataline mode.
5. Software needs to configure the Command Argument Register to set argument if needed (no need in normal fast boot).
6. Software must configure the Transfer Type Register to start the boot process. In normal boot mode, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept at the default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1.
7. DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1, it is recommended to configure the number of blocks in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
8. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If a boot timeout happens (ack times out or the first data read times out), an interrupt will be triggered, and software must configure MMC Boot Register to bit 6 to 0 to disable boot. This makes CMD high, then after at least 56 clocks, it is ready to begin a normal initialization process.
9. If there is no timeout, software needs to determine when the data read is finished and then configure MMC Boot Register bit 6 to 0 to disable boot. This will make CMD line high and command completed asserted. After at least 56 clocks, it is ready to begin normal initialization process.
10. Reset the host and then can begin the normal process.
26.6.6.2 Alternative fast boot flow

1. Software needs to configure init_active bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot), and bit 5 to 1 (alternative boot), and bit 4 to select the ack mode or not. If data needs to be sent through DMA mode, then configure bit 7 to enable the automatic stop at block gap feature. Software should also configure bit 3-bit 0 to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure Block Attributes Register to set the block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes.
4. Software needs to configure the Protocol control register to set the DTW (data transfer width). If in ddr fast boot mode, DTW only can be configure to 4-bit/8-bit dataline mode.
5. Software needs to configure Command Argument Register to set argument to 0xFFFFFFF.
6. Software needs to configure the Transfer Type Register to start the boot process by CMD0 with 0xFFFFFFF argument. In alternative boot, CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. Note DMAEN should be configured as 0 in polling mode. And if BCEN is configured as 1 in polling mode, it is recommended to configure the block count in the Block Attributes Register to the maximum value. If in DDR fast boot mode, DDR_EN needs to be set to 1.
7. When the step 6 is configured, the boot process will begin. Software needs to poll the data buffer ready status to read the data from the buffer in time. If there is a boot timeout (ack data timeout in 50ms or data timeout in 1s), the host will send out the interrupt and software needs to send CMD0 with reset and then configure the boot enable bit to 0 to stop this process.
8. If there is no time out, software needs to decide when to stop the boot process, and send out the CMD0 with reset and then after the command is completed, configure the MMC Boot Register bit 6 to stop the process. After 8 clocks from the command completion, the slave (card) is ready for the identification step.
9. Reset the host and then begin the normal process.

26.6.6.3 Fast boot application case (in DMA mode)

In the boot application case, because the image destination and the image size are contained in the beginning of the image, it is necessary to switch DMA parameters on the fly during MMC fast boot.
In fast boot, the host can use ADMA2 (Advanced DMA2) with two destinations.

The detail flow is described below:

1. Software needs to configure INIT_ACTIVE bit (system control register bit 27) to make sure 74 card clocks are finished.
2. Software needs to configure the MMC Boot Register (offset 0xc4) bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot) or 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 to enable the automatic stop at block gap feature. Also configure bits[31-16] to set the (BLK_CNT - VALUE1). Here VALUE1 is the value of the block count that needs to transfer the first time, so that the host will stop at the block gap when the uSDHC controller gets VAULE1 blocks from the device. Also configure bits[3-0] to select the ack timeout value according to the SD clock frequency.
3. Software then needs to configure the Block Attributes Register to set block size and count. If in DDR fast boot mode, the block size only can be configured to 512 bytes. In DMA mode, it is recommended to set the block count (BLK_CNT) to the max value (16'hffff). Software needs to configure Protocol Control Register to set DTW (data transfer width). If in DDR fast boot mode, the DTW only can be configured to 4-bit/8-bit dataline mode.
4. Software enable ADMA2 by configuring Protocol Control Register bits [9-8].
5. Software need to set at least three pairs ADMA2 descriptor in boot memory (ie, in IRAM, at least 6 word). The first pair descriptor define the start address (ie, IRAM) and data length (ie, 512 byte * VALUE1) of fisrt part boot code. Software also need to set the second pair descriptor, the second start address (any value that is writeable), data length is suggest to set 1~2word(record as VALUE2). Note: the second couple desc also transfer useful data even at lease 1 word. Because our ADMA2 can't support 0 data_length data transfer descriptor.
6. Software needs to configure Command Argument Register to set argument to 0xFFFFFFFF in alternative fast boot, and don't need set in normal fast boot.
7. Software needs to configure Transfer Type Register to start the boot process. CMDINX, CMDTYP, RSPTYP, CICEN, CCCEN, AC12EN, BCEN and DMAEN are kept default value. DPSEL bit is set to 1, DTDSEL is set to 1, MSBSEL is set to 1. DMAEN is configured as 1 in DMA mode. And if BCEN is configured as 1, better to configure blk no in Bock Attributes Register to the max value. And if in ddr fast boot mode, DDR_EN need to be set to 1.
8. When the step 8 is configured, boot process will begin, the first VALUE1 block number data has transfer. Software need to polling TC bit (bit1 in Interrupt Status Register) to determine first transfer is end. Also software need to polling BGE bit (bit2 in Interrupt Status Register) to determine if first transfer stop at block gap.
10. When TC, BGE bit is 1, SW can analyzes the first code of VALUE1 block, initializes the new memory device, if required, and sets the third pair of descriptors to define the start address and length of the remaining part of boot code (VALUE3 the remain boot code block). Remember set the last descriptor with END.

11. Software needs to configure MMC Boot Register (offset 0xc4) again. Set bit 6 to 1 (enable boot); and bit 5 to 0 (normal fast boot), to 1 (alternative boot); and bit 4 to select the ack mode or not. In DMA mode, configure bit 7 to 1 for enable automatically stop at block gap feature. Also configure bit31-bit16 to set the \((BLK_CNT - (VALUE1+1+VALUE3))\), that host will stop at block gap when the uSDHC controller gets \((VALUE1+1+VALUE3)) blocks from device totally include the blocks received in step 9. And need to configure bit 3-bit0 to select the ack timeout value according to the sd clk frequency. Please note, Software doesn't need to configure the \(BLK_CNT\) again, because it's counted down automatically by the uSDHC controller.

12. Software needs to clear TC and BGE bit. And software needs to clear SABGREQ(bit 16 in Protocol control register), and set CREQ(bit17 Protocol control register) to 1 to resume the data transfer. Host will transfer the VALUE2 and VALUE3 data to the destination that is set by descriptor.

13. Software need to polling BGE bit to determine if the fast boot is over.

Note:

1. When ADMA boot flow is started, for uSDHC, it is like a normal ADMA read operation. So setting ADMA2 descriptor as the normal ADMA2 transfer.
2. Need a few words length memory to keep descriptor.
3. For the 1~2 word data in second descriptor setting, it is the useful data, so software need to deal the data due to the application case.

26.7 Commands for MMC/SD/SDIO

A table containing the list of commands for the MMC/SD/SDIO cards can be found here. Refer to the corresponding specifications for more details about the command information.

There are four kinds of commands defined to control the MultiMediaCard:

1. broadcast commands (bc), no response.
2. broadcast commands with response (bcr), response from all cards simultaneously.
3. addressed (point-to-point) commands (ac), no data transfer on the DATA.
4. addressed (point-to-point) data transfer commands (adtc).
Response: a response is a token which is sent from the card to the host as an answer to a previously received command. A response is transferred serially on the CMD line.

Table 26-4. Commands for MMC/SD/SDIO Cards

</table>

1. CMD3 differs for MMC and SD cards. For MMC cards, it is referred to as SET_RELATIVE_ADDR, with a response type of R1. For SD cards, it is referred to as SEND_RELATIVE_ADDR, with a response type of R6 (with RCA inside).
2. CMD6 differs completely between high speed MMC cards and high speed SD cards. Command SWITCH_FUNC is for high speed SD cards.
3. Command SWITCH is for high speed MMC cards. The Index field can contain any value from 0-255, but only values 0-191 are valid. If the Index value is in the 192-255 range the card does not perform any modification and the SWITCH_ERROR status bit in the EXT_CSD register is set. The Access Bits are shown in Table 2.
4. ACMDs shall be preceded with the APP_CMD command. (Commands listed are used for SD only, other SD commands not listed are not supported on this module).

The Access Bits for the EXT_CSD Access Modes are shown below.

</table>
26.8 Software Restrictions

26.8.1 Initialization Active
The driver cannot set INITA bit in System Control register when any of the command line or data lines is active, so the driver must ensure both CDIHB and CIHB bits are cleared.

26.8.2 Software Polling Procedure
For polling read or write, once the software begins a buffer read or write, it must access exactly the number of times as the values set in the Watermark Level Register; moreover, if the block size is not a multiple of the value in Watermark Level Register (read and write respectively), the software must access exactly the remaining number of words at the end of each block.

For example, for a read operation, if the RD_WML is 4, indicating the watermark level is 16 bytes, block size is 40 bytes, and the block number is 2, then the access times for the burst sequence in the whole transfer process must be 4, 4, 2, 4, 4, 2.

26.8.3 Suspend Operation
In order to suspend the data transfer, the software must inform uSDHC that the suspend command is successfully accepted. To achieve this, after the Suspend command is accepted by the SDIO card, software must send another normal command marked as suspend command (CMDTYP bits set as '01') to inform uSDHC that the transfer is suspended.

If software needs to resume the suspended trasnfer, it should read the value in BLKCNT register to save the remaining number of blocks before sending the normal command marked as suspend, otherwise on sending such 'suspend' command, uSDHC will regard the current transfer is aborted and change BLKCNT register to its original value, instead of keeping the remained number of blocks.
26.8.4  Data Length Setting

For either ADMA (ADMA1 or ADMA2) transfer, the data in the data buffer must be word aligned, so the data length set in the descriptor must be a multiple of 4.

26.8.5  (A)DMA Address Setting

To configure ADMA1/ADMA2/DMA address register, when TC bit is set, the register will always update itself with the internal address value to support dynamic address synchronization, so the software must ensure that the TC bit is cleared prior to configuring ADMA1/ADMA2/DMA address register.

26.8.6  Data Port Access

Data Port does not support parallel access. For example, during an internal DMA access, it is not allowed to write any data to the Data Port by CPU; or during a CPU read operation, it is also prohibited to write any data to the Data Port, by either CPU or internal DMA. Otherwise the data would be corrupted inside the uSDHC buffer.

26.8.7  Change Clock Frequency

uSDHC does not automatically gate off the card clock when the Host Driver changes the clock frequency. To prevent possible glitch on the card clock, clear the FRC_SDCLK_ON bit when changing clock divisor value(SDCLKFS or DVS in System Control Register) or setting RSTA bit.

Also before changing the clock divisor value, Host Driver should make sure the SDSTB bit is high.

26.8.8  Multi-block Read

For pre-defined multi-block read operation, i.e., the number of blocks to read has been defined by previous CMD23 for MMC, or pre-defined number of blocks in CMD53 for SDIO/SDCombo, or whatever multi-block read without abort command at card side, an abort command, either automatic or manual CMD12/CMD52, is still required by uSDHC after the pre-defined number of blocks are done, to drive the internal state machine to idle mode.
In this case, the card may not respond to this extra abort command and uSDHC will get Response Timeout. It is recommended to manually send an abort command with RSPTYP[1:0] both bits cleared.

## 26.9 uSDHC Memory Map/Register Definition

### 26.9.1 uSDHC register descriptions

This section includes the module memory map and detailed descriptions of all registers. See the table below for the register memory map for the uSDHC. All these registers only support 32-bit accesses.

**NOTE**

The uSDHC registers are 32-bit wide and only support 32-bit access.

### 26.9.1.1 uSDHC Memory map

Base address: 402C_0000h for uSDHC1, 402C_4000h for uSDHC2.

</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>DS_ADDR</td>
</tr>
<tr>
<td>DS_ADDR</td>
<td><strong>DMA System Address / Argument 2</strong></td>
</tr>
<tr>
<td></td>
<td>When ACMD23_ARGU2_EN is set to 0, SDMA uses this register as system address and supports only 32-bit addressing mode. Auto CMD23 cannot be used with SDMA. When ACMD23_ARGU2_EN is set to 1, SDMA uses ADMA System Address register (05Fh – 058h) instead of this register to support both 32-bit and 64-bit addressing. This register is used only for Argument2 and SDMA may use Auto CMD23.</td>
</tr>
</tbody>
</table>

1. **SDMA System Address**

   Since the address must be word (4 bytes) aligned, the least 2 bits are reserved, always 0. When the uSDHC stops a DMA transfer, this register points out the system address of the next contiguous data position. It can be accessed only when no transaction is executing (i.e. after a transaction has stopped). Read operation during transfers may return an invalid value. The Host Driver shall initialize this register before starting a DMA transaction. After DMA has stopped, the system address of the next contiguous data position can be read from this register.

   This register is protected during a data transfer. When data lines are active, write to this register is ignored. The Host driver shall wait, until the DLA bit in the Present State register is cleared, before writing to this register.

   The uSDHC internal DMA does not support a virtual memory system. It only supports continuous physical memory access. And due to AHB burst limitations, if the burst must cross the 1 KB boundary, uSDHC will automatically change SEQ burst type to NSEQ.

   Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions.

2. **Argument 2**

   This register is used with the Auto CMD23 to set a 32-bit block count value to the argument of the CMD23 while executing Auto CMD23.

   If Auto CMD23 is used with ADMA, the full 32-bit block count value can be used. If Auto CMD23 is used without ADMA, the available block count value is limited by the Block Count register. 65535 blocks is the maximum value in this case.

26.9.1.3.4 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-16</td>
<td>Block Count For Current Transfer:</td>
</tr>
<tr>
<td>BLKCNT</td>
<td>This register is enabled when the Block Count Enable bit in the Transfer Mode register is set to 1 and is valid only for multiple block transfers. For single block transfer, this register will always read as 1. The Host Driver shall set this register to a value between 1 and the maximum block count. The uSDHC decrements the block count after each block transfer and stops when the count reaches zero. Setting the block count to 0 results in no data blocks being transferred.</td>
</tr>
</tbody>
</table>

This register should be accessed only when no transaction is executing (i.e. after transactions are stopped). During data transfer, read operations on this register may return an invalid value and write operations are ignored.

When saving transfer content as a result of a Suspend command, the number of blocks yet to be transferred can be determined by reading this register. The reading of this register should be applied after transfer is paused by stop at block gap operation and before sending the command marked as suspend.

Table continues on the next page...
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This is because when Suspend command is sent out, uSDHC will regard the current transfer is aborted and change BLKCNT register back to its original value instead of keeping the dynamical indicator of remained block count. When restoring transfer content prior to issuing a Resume command, the Host Driver shall restore the previously saved block count. <strong>NOTE:</strong> Although the BLKCNT field is 0 after reset, the read of reset value is 0x1. This is because when MSBSEL bit is indicating a single block transfer, the read value of BLKCNT is always 1.</td>

26.9.1.5.2 Function

This register is used to control the operation of data transfers. The Host Driver shall set this register before issuing a command followed by a data transfer, or before issuing a Resume command. To prevent data loss, the uSDHC prevents writing to the bits, that are involved in the data transfer of this register, when data transfer is active. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN and DMAEN.
The Host Driver shall check the Command Inhibit DAT bit (CDIHB) and the Command Inhibit CMD bit (CIHB) in the Present State register before writing to this register. When the CDIHB bit in the Present State register is set, any attempt to send a command with data by writing to this register is ignored; when the CIHB bit is set, any write to this register is ignored.

On sending commands with data transfer involved, it is mandatory that the block size is non-zero. Block count must also be non-zero, or indicated as single block transfer (bit 5 of this register is '0' when written), or block count is disabled (bit 1 of this register is '0' when written), otherwise uSDHC will ignore the sending of this command and do nothing. For write command, with all above restrictions, it is also mandatory that the write protect switch is not active (WPSPL bit of Present State Register is '1'), otherwise uSDHC will also ignore the command.

If the commands with data transfer does not receive the response in 64 clock cycles, i.e., response time-out, uSDHC will regard the external device does not accept the command and abort the data transfer. In this scenario, the driver should issue the command again to re-try the transfer. It is also possible that for some reason the card responds the command but uSDHC does not receive the response, and if it is internal DMA (either simple DMA or ADMA) read operation, the external system memory is over-written by the internal DMA with data sent back from the card.

The table below shows the summary of how register settings determine the type of data transfer.

**Table 26-6. Transfer Type Register Setting for Various Transfer Types**

<table>
<thead>
<tr>
<th>Multi/Single Block Select</th>

<td>1</td>
<td>R1b,R5b</td>
</tr>
</tbody>
</table>
• In the SDIO specification, response type notation for R5b is not defined. R5 includes R5b in the SDIO specification. But R5b is defined in this specification to specify that the uSDHC will check the busy status after receiving a response. For example, usually CMD52 is used with R5, but the I/O abort command shall be used with R5b.
• The CRC field for R3 and R4 is expected to be all 1 bits. The CRC check shall be disabled for these response types.

<tr>
<td>CMDTYP</td>
<td>There are three types of special commands: Suspend, Resume and Abort. These bits shall be set to 00b for all other commands.</td>
</tr>
<tr>
<td></td>
<td>• Suspend Command: If the Suspend command succeeds, the uSDHC shall assume that the card bus has been released and that it is possible to issue the next command which uses the DATA line. Since the uSDHC does not monitor the content of command response, it does not know if the Suspend command succeeded or not. It is the Host Driver's responsibility to check the status of the Suspend command and send another command marked as Suspend to inform the uSDHC that a Suspend command was successfully issued. Refer to Suspend Resume for more details. After the end bit of command is sent, the uSDHC de-asserts Read Wait for read transactions and stops checking busy for write transactions. In 4-bit mode, the interrupt cycle starts. If the Suspend command fails, the uSDHC will maintain its current state, and the Host Driver shall restart the transfer by setting the Continue Request bit in the Protocol Control register.</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
### Field | Function
--- | ---
| | • Resume Command: The Host Driver re-starts the data transfer by restoring the registers saved before sending the Suspend Command and then sends the Resume Command. The uSDHC will check for a pending busy state before starting write transfers.  
• Abort Command: If this command is set when executing a read transfer, the uSDHC will stop reads to the buffer. If this command is set when executing a write transfer, the uSDHC will stop driving the DATA line. After issuing the Abort command, the Host Driver should issue a software reset (Abort Transaction).  
00b - Normal Other commands  
01b - Suspend CMD52 for writing Bus Suspend in CCCR  
10b - Resume CMD52 for writing Function Select in CCCR  
11b - Abort CMD12, CMD52 for writing I/O Abort in CCCR
| 21 | DPSEL | Data Present Select  
This bit is set to 1 to indicate that data is present and shall be transferred using the DATA line. It is set to 0 for the following:  
• Commands using only the CMD line (e.g. CMD52).  
• Commands with no data transfer, but using the busy signal on DATA0 line (R1b or R5b e.g. CMD38)  
**NOTE:** In resume command, this bit shall be set, and other bits in this register shall be set the same as when the transfer was initially launched. When the Write Protect switch is on, (i.e. the WPSPL bit is active as ‘0’), any command with a write operation will be ignored. That is to say, when this bit is set, while the DTDSEL bit is 0, writes to the register Transfer Type are ignored.  
0b - No Data Present  
1b - Data Present
| 20 | CICEN | Command Index Check Enable  
If this bit is set to 1, the uSDHC will check the Index field in the response to see if it has the same value as the command index. If it is not, it is reported as a Command Index Error. If this bit is set to 0, the Index field is not checked.  
0b - Disable  
1b - Enable
| 19 | CCCEN | Command CRC Check Enable  
If this bit is set to 1, the uSDHC shall check the CRC field in the response. If an error is detected, it is reported as a Command CRC Error. If this bit is set to 0, the CRC field is not checked. The number of bits checked by the CRC field value changes according to the length of the response. (Refer to RSPTYP[1:0] and Command Transfer Type (CMD_XFR_TYP).)  
0b - Disable  
1b - Enable
| 18 | — | Reserved
| 17-16 | RSPTYP | Response Type Select  
00b - No Response  
01b - Response Length 136  
10b - Response Length 48  
11b - Response Length 48, check Busy after response

26.9.1.9.2  Function

This register is used to store part 3 of the response bits from the card.

The table below describes the mapping of command responses from the SD Bus to Command Response registers for each response type. In the table, R[ ] refers to a bit range within the response data as transmitted on the SD Bus.

### Table 26-8. Response Bit Definition for Each Response Type

<tr>
<td>R6 (Publish RCA)</td>
<td>New Published RCA[31:16] and card status[15:0]</td>
<td>R[39:9]</td>
<td>CMDRSP0</td>
</tr>
</tbody>
</table>

This table shows that most responses with a length of 48 (R[47:0]) have 32-bits of the response data (R[39:8]) stored in the CMDRSP0 register. Responses of type R1b (Auto CMD12 responses) have response data bits (R[39:8]) stored in the CMDRSP3 register. Responses with length 136 (R[135:0]) have 120-bits of the response data (R[127:8]) stored in the CMDRSP0, 1, 2, and 3 registers.

To be able to read the response status efficiently, the uSDHC only stores part of the response data in the Command Response registers. This enables the Host Driver to efficiently read 32-bits of response data in one read cycle on a 32-bit bus system. Parts of the response, the Index field and the CRC, are checked by the uSDHC (as specified by the Command Index Check Enable and the Command CRC Check Enable bits in the Transfer Type register) and generate an error interrupt if any error is detected. The bit range for the CRC check depends on the response length. If the response length is 48, the uSDHC will check R[47:1], and if the response length is 136 the uSDHC will check R[119:1].

Since the uSDHC may have a multiple block data transfer executing concurrently with a CMD_wo_DAT command, the uSDHC stores the Auto CMD12 response in the CMDRSP3 register. The CMD_wo_DAT response is stored in CMDRSP0. This allows the uSDHC to avoid overwriting the Auto CMD12 response with the CMD_wo_DAT and vice versa. When the uSDHC modifies part of the Command Response registers, as shown in the table above, it preserves the unmodified bits.

<td>24h</td>
</tr>
</tbody>
</table>

#### 26.9.1.11.2 Function

The Host Driver can get status of the uSDHC from this 32-bit read only register.

- The Host Driver can issue CMD0, CMD12, CMD13 (for memory) and CMD52 (for SDIO) when the DATA lines are busy during a data transfer. These commands can be issued when Command Inhibit (CMD) is set to zero. Other commands shall be issued when Command Inhibit (DATA) is set to zero. Possible changes to the SD Physical Specification may add other commands to this list in the future.
- Note: the reset value of Present State Register depend on board connectivity.

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>CDPL</td>
<td>This bit reflects the inverse value of the CD_B pin for the card socket. Debouncing is not performed on this bit. This bit may be valid, but is not guaranteed, because of propagation delay. Use of this bit is limited to testing since it must be debounced by software. A software reset does not affect this bit. A write to the Force Event Register does not affect this bit. The reset value is effected by the external card detection pin. This bit shows the value on the CD_B pin (i.e. when a card is inserted in the socket, it is 0 on the CD_B input, and consequently the CDPL reads 1.)</td>
</tr>
</tbody>
</table>
|       | 0b - No card present (CD_B = 1)  
|       | 1b - Card present (CD_B = 0)  |
| 17    | -  
|       | Reserved  |
| 16    | Card Inserted  
| CINST | This bit indicates whether a card has been inserted. The uSDHC debounces this signal so that the Host Driver will not need to wait for it to stabilize. Changing from a 0 to 1 generates a Card Insertion interrupt in the Interrupt Status register. Changing from a 1 to 0 generates a Card Removal interrupt in the Interrupt Status register. A write to the Force Event Register does not affect this bit. |
|       | 0b - Power on Reset or No Card  
|       | 1b - Card Inserted  |
| 15    | Tape Select Change Done  
| TSCD  | This bit indicates the dealy setting is effective after write CLK_TUNE_CTRL_STATUS register.  
|       | 0b - Delay cell select change is not finished.  
|       | 1b - Delay cell select change is finished.  |
| 14-13 | -  
|       | Reserved  |
| 12    | Re-Tuning Request (only for SD3.0 SDR104 mode and EMMC HS200 mode)  
| RTR   | Host Controller may request Host Driver to execute re-tuning sequence by setting this bit when the data window is shifted by temperature drift and a tuned sampling point does not have a good margin to receive correct data.  
|       | This bit is cleared when a command is issued with setting Execute Tuning bit in MIXER_CTRL register.  
|       | Changing of this bit from 0 to 1 generates Re-Tuning Event. Refer to Interrupt status registers for more detail.  
|       | This bit isn't set to 1 if Sampling Clock Select in the MIXER_CTRL register is set to 0 (using fixed sampling clock).  
|       | 0b - Fixed or well tuned sampling clock  
|       | 1b - Sampling clock needs re-tuning  |
| 11    | Buffer Read Enable  
| BREN  | This status bit is used for non-DMA read transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates that valid data exists in the host side buffer. If this bit is high, valid data greater than the watermark level exist in the buffer. A change of this bit from 1 to 0 occurs when some reads from the buffer(read DATPORT (Base + 0x20)) are made and the buffer hasn't valid data greater than the watermark level. A change of this bit from 0 to1 occurs when there is enough valid data ready in the buffer and the Buffer Read Ready interrupt has been generated and enabled.  
|       | 0b - Read disable  
|       | 1b - Read enable  |
| 10    | Buffer Write Enable  

Table continues on the next page...
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| BWEN  | This status bit is used for non-DMA write transfers. The uSDHC implements an internal buffer to transfer data efficiently. This read only flag indicates if space is available for write data. If this bit is 1, valid data greater than the watermark level can be written to the buffer. A change of this bit from 1 to 0 occurs when some writes to the buffer(write DATPORT(Base + 0x20)) are made and the buffer hasn’t valid space greater than the watermark level. A change of this bit from 0 to 1 occurs when the buffer can hold valid data greater than the write watermark level and the Buffer Write Ready interrupt is generated and enabled.  
0b - Write disable  
1b - Write enable |
| 9     | Read Transfer Active  
This status bit is used for detecting completion of a read transfer.  
This bit is set for either of the following conditions:  
• After the end bit of the read command.  
• When writing a 1 to the Continue Request bit in the Protocol Control register to restart a read transfer.  
A Transfer Complete interrupt is generated when this bit changes to 0. This bit is cleared for either of the following conditions:  
• When the last data block as specified by block length is transferred to the System, i.e. all data are read away from uSDHC internal buffer.  
• When all valid data blocks have been transferred from uSDHC internal buffer to the System and no current block transfers are being sent as a result of the Stop At Block Gap Request being set to 1.  
0b - No valid data  
1b - Transferring data |
| 8     | Write Transfer Active  
This status bit indicates a write transfer is active. If this bit is 0, it means no valid write data exists in the uSDHC.  
This bit is set in either of the following cases:  
• After the end bit of the write command.  
• When writing 1 to the Continue Request bit in the Protocol Control register to restart a write transfer.  
This bit is cleared in either of the following cases:  
• After getting the CRC status of the last data block as specified by the transfer count (Single and Multiple).  
• After getting the CRC status of any block where data transmission is about to be stopped by a Stop At Block Gap Request.  
During a write transaction, a Block Gap Event interrupt is generated when this bit is changed to 0, as result of the Stop At Block Gap Request being set. This status is useful for the Host Driver in determining when to issue commands during Write Busy state.  
0b - No valid data  
1b - Transferring data |
| 7     | SD Clock Gated Off Internally  
This status bit indicates that the SD Clock is internally gated off, because of buffer over / under-run or read pause without read wait assertion, or the driver set FRC_SDCLK_ON bit is 0 to stop the SD clock in idle status. Set IPG_PERCLK_SOFT_EN and CARD_CLK_SOFT_EN to 0 also gate off SD clock. This bit is for the Host Driver to debug data transaction on the SD bus.  
0b - SD Clock is active.

*Table continues on the next page...*
### Field | Function
--- | ---
|  | After the end bit of the write command. When writing to 1 to the Continue Request bit in the Protocol Control register to continue a write transfer.
|  | This bit will be cleared in either of the following cases:
|  | When the SD card releases Write Busy of the last data block, the uSDHC will also detect if the output is not busy. If the SD card does not drive the busy signal after the CRC status is received, the uSDHC shall assume the card drive "Not Busy".
|  | When the SD card releases write busy, prior to waiting for write transfer, and as a result of a Stop At Block Gap Request.
|  | In the case of command with busy pending:
|  | This status indicates that a busy state follows the command and the data line is in use. This bit will be cleared when the DATA0 line is released.
|  | NOTE: The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0.
|  | Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register.
| 0 | Command Inhibit (DATA)
| CDIH B | This status bit is generated if either the DAT Line Active or the Read Transfer Active is set to 1. If this bit is 0, it indicates that the uSDHC can issue the next SD / MMC Command. Commands with a busy signal belong to Command Inhibit (DATA) (for example. R1b, R5b type). Changing from 1 to 0 generates a Transfer Complete interrupt in the Interrupt Status register.
|  | NOTE: The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0.
|  | 0b - Can issue command which uses the DATA line
|  | 1b - Cannot issue command which uses the DATA line
| 0 | Command Inhibit (CMD)
| CIHB | If this status bit is 0, it indicates that the CMD line is not in use and the uSDHC can issue a SD / MMC Command using the CMD line.
|  | This bit is set also immediately after the Transfer Type register is written. This bit is cleared when the command response is received. Even if the Command Inhibit (DATA) is set to 1, Commands using only the CMD line can be issued if this bit is 0. Changing from 1 to 0 generates a Command Complete interrupt in the Interrupt Status register. If the uSDHC cannot issue the command because of a command conflict error (Refer to Command CRC Error) or because of a Command Not Issued By Auto CMD12 Error, this bit will remain 1 and the Command Complete is not set. The Status of issuing an Auto CMD12 does not show on this bit.
|  | NOTE: The SD Host Driver can save registers for a suspend transaction after this bit has changed from 1 to 0.
|  | 0b - Can issue command using only CMD line
|  | 1b - Cannot issue command

26.9.1.12.2 Function

There are three cases to restart the transfer after stop at the block gap. Which case is appropriate depends on whether the uSDHC issues a Suspend command or the SD card accepts the Suspend command.

1. If the Host Driver does not issue a Suspend command, the Continue Request shall be used to restart the transfer.
2. If the Host Driver issues a Suspend command and the SD card accepts it, a Resume command shall be used to restart the transfer.
3. If the Host Driver issues a Suspend command and the SD card does not accept it, the Continue Request shall be used to restart the transfer.

Any time Stop At Block Gap Request stops the data transfer, the Host Driver shall wait for a Transfer Complete (in the Interrupt Status register), before attempting to restart the transfer. When restarting the data transfer by Continue Request, the Host Driver shall clear the Stop At Block Gap Request before or simultaneously.

</tbody>
</table>

**Field: NON_EXACT_BLK_RD**
Current block read is non-exact block read. It is only used for SDIO.

- **0b**: The block read is exact block read. Host driver doesn’t need to issue abort command to terminate this multi-block read.
- **1b**: The block read is non-exact block read. Host driver needs to issue abort command to terminate this multi-block read.

**Field: BURST_LEN_E**
BURST length enable for INCR, INCR4 / INCR8 / INCR16, INCR4-WRAP / INCR8-WRAP / INCR16-WRAP

This is used to enable / disable the burst length for the external AHB2AXI bridge. It is useful especially for INCR transfer because without burst length indicator, the AHB2AXI bridge does not know the burst length in advance. Without burst length indicator, AHB INCR transfers can only be converted to SINGLEs on the AXI side.

- **1xxb**: Burst length is enabled for INCR4-WRAP / INCR8-WRAP / INCR16-WRAP
- **x1xb**: Burst length is enabled for INCR4 / INCR8 / INCR16
- **xx1b**: Burst length is enabled for INCR

**Field: WECRM**
Wakeup Event Enable On SD Card Removal

This bit enables a wakeup event, via a Card Removal, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Removal Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Removal Status and the uSDHC interrupt.

- **0b**: Disable
- **1b**: Enable

**Field: WECINS**
Wakeup Event Enable On SD Card Insertion

This bit enables a wakeup event, via a Card Insertion, in the Interrupt Status register. FN_WUS (Wake Up Support) in CIS does not effect this bit. When this bit is set, the Card Insertion Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Insertion Status and the uSDHC interrupt.

- **0b**: Disable
- **1b**: Enable

**Field: WECINT**
Wakeup Event Enable On Card Interrupt

This bit enables a wakeup event, via a Card Interrupt, in the Interrupt Status register. This bit can be set to 1 if FN_WUS (Wake Up Support) in CIS is set to 1. When this bit is set, the Card Interrupt Status and the uSDHC interrupt can be asserted without CLK toggling. When the wakeup feature is not enabled, the CLK must be active in order to assert the Card Interrupt Status and the uSDHC interrupt.

- **0b**: Disable
- **1b**: Enable

**Field: RD_DONE_NO_8CLK**
Read done no 8 clock:

According to the SD/MMC spec, for read data transaction, 8 clocks are needed after the end bit of the last data block. So, by default(RD_DONE_NO_8CLK=0), 8 clocks will be active after the end bit of the last read data transaction.

However, this 8 clocks should not be active if user wants to use stop at block gap(include the auto stop at block gap in boot mode) feature for read and the RWCTL bit(bit18) is not enabled. In this case, software should set RD_DONE_NO_8CLK to avoid this 8 clocks. Otherwise, the device may send extra data to uSDHC while uSDHC ignores these data.

<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>19 IABG</td>
<td>Interrupt At Block Gap</td>
</tr>
<tr>
<td></td>
<td>This bit is valid only in 4-bit mode, of the SDIO card, and selects a sample point in the interrupt cycle. Setting to 1 enables interrupt detection at the block gap for a multiple block transfer. Setting to 0 disables interrupt detection during a multiple block transfer. If the SDIO card cannot signal an interrupt during a multiple block transfer, this bit should be set to 0 to avoid an inadvertent interrupt. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card.</td>
</tr>
<tr>
<td></td>
<td>0b - Disabled</td>
</tr>
<tr>
<td></td>
<td>1b - Enabled</td>
</tr>
<tr>
<td>18 RWCTL</td>
<td>Read Wait Control</td>
</tr>
<tr>
<td></td>
<td>The read wait function is optional for SDIO cards. If the card supports read wait, set this bit to enable use of the read wait protocol to stop read data using the DATA2 line. Otherwise the uSDHC has to stop the SD Clock to hold read data, which restricts commands generation. When the Host Driver detects an SDIO card insertion, it shall set this bit according to the CCCR of the card. If the card does not support read wait, this bit shall never be set to 1, otherwise DATA line conflicts may occur. If this bit is set to 0, stop at block gap during read operation is also supported, but the uSDHC will stop the SD Clock to pause reading operation.</td>
</tr>
<tr>
<td></td>
<td>0b - Disable Read Wait Control, and stop SD Clock at block gap when SABGREQ bit is set</td>
</tr>
<tr>
<td></td>
<td>1b - Enable Read Wait Control, and assert Read Wait without stopping SD Clock at block gap when SABGREQ bit is set</td>
</tr>
<tr>
<td>17 CREQ</td>
<td>Continue Request</td>
</tr>
<tr>
<td></td>
<td>This bit is used to restart a transaction which was stopped using the Stop At Block Gap Request. When a Suspend operation is not accepted by the card, it is also by setting this bit to restart the paused transfer. To cancel stop at the block gap, set Stop At Block Gap Request to 0 and set this bit to 1 to restart the transfer.</td>
</tr>
<tr>
<td></td>
<td>The uSDHC automatically clears this bit, therefore it is not necessary for the Host Driver to set this bit to 0. If both Stop At Block Gap Request and this bit are 1, the continue request is ignored.</td>
</tr>
<tr>
<td></td>
<td>0b - No effect</td>
</tr>
<tr>
<td></td>
<td>1b - Restart</td>
</tr>
<tr>
<td>16 SABGREQ</td>
<td>Stop At Block Gap Request</td>
</tr>
<tr>
<td></td>
<td>This bit is used to stop executing a transaction at the next block gap for both DMA and non-DMA transfers. Until the Transfer Complete is set to 1, indicating a transfer completion, the Host Driver shall leave this bit set to 1. Clearing both the Stop At Block Gap Request and Continue Request does not cause the transaction to restart. Read Wait is used to stop the read transaction at the block gap. The uSDHC will honor the Stop At Block Gap Request for write transfers, but for read transfers it requires that the SDIO card support Read Wait. Therefore, the Host Driver shall not set this bit during read transfers unless the SDIO card supports Read Wait and has set the Read Wait Control to 1, otherwise the uSDHC will stop the SD bus clock to pause the read operation during block gap. In the case of write transfers in which the Host Driver writes data to the Data Port register, the Host Driver shall set this bit after all block data is written. If this bit is set to 1, the Host Driver shall not write data to the Data Port register after a block is sent. Once this bit is set, the Host Driver shall not clear this bit before the Transfer Complete bit in Interrupt Status Register is set, otherwise the uSDHCs behavior is undefined.</td>

|       | 1111b - SDCLK x $2^{29}$  |
| 15-8  | SDCLK Frequency Select |
|       | This register is used to select the frequency of the SDCLK pin. The frequency is not programmed directly, rather this register holds the prescaler (this register) and divisor (next register) of the Base Clock Frequency register. In Single Data Rate mode (DDR_EN bit of MIXERCTRL is '0') Only the following settings are allowed:  
|       | 80h) Base clock divided by 256  
|       | 40h) Base clock divided by 128  
|       | 20h) Base clock divided by 64  
|       | 10h) Base clock divided by 32  
|       | 08h) Base clock divided by 16  
|       | 04h) Base clock divided by 8  
|       | 02h) Base clock divided by 4  
|       | 01h) Base clock divided by 2  
|       | 00h) Base clock divided by 1  
|       | While in Dual Data Rate mode (DDR_EN bit of MIXERCTRL is '1') Only the following settings are allowed:  
|       | 80h) Base clock divided by 512  
|       | 40h) Base clock divided by 256  
|       | 20h) Base clock divided by 128  
|       | 10h) Base clock divided by 64  
|       | 08h) Base clock divided by 32  
|       | 04h) Base clock divided by 16  
|       | 02h) Base clock divided by 8  
|       | 01h) Base clock divided by 4  
|       | 00h) Base clock divided by 2  
|       | When S/W changes the DDR_EN bit, SDCLKFS may need to be changed also! In Single Data Rate mode, setting 00h bypasses the frequency prescaler of the SD Clock. |

Table continues on the next page...
Multiple bits must not be set, or the behavior of this prescaler is undefined. The two default divider values can be calculated by the frequency of ipg_perclk and the following Divisor bits.

The frequency of SDCLK is set by the following formula:

\[
\text{Clock Frequency} = \frac{\text{Base Clock}}{(\text{prescaler} \times \text{divisor})}
\]

For example, in Single Data Rate mode, if the Base Clock Frequency is 96 MHz, and the target frequency is 25 MHz, then choosing the prescaler value of 01h and divisor value of 1h will yield 24 MHz, which is the nearest frequency less than or equal to the target. Similarly, to approach a clock value of 400 kHz, the prescaler value of 08h and divisor value of eh yields the exact clock value of 400 kHz.

The reset value of this bit field is 80h, so if the input Base Clock (ipg_perclk) is about 96 MHz, the default SD Clock after reset is 375 kHz.

According to the SD Physical Specification Version 1.1 and the SDIO Card Specification Version 1.2, the maximum SD Clock frequency is 50 MHz and shall never exceed this limit.

Before changing clock divisor value (SDCLKFS or DVS), Host Driver should make sure the SDSTB bit is high.

If setting SDCLKFS and DVS can generate same clock frequency,(For example, in SDR mode, SDCLKFS = 01h is same as DVS = 01h.) SDCLKFS is highly recommended.

### 26.9.1.14 Interrupt Status (INT_STATUS)

<tbody>
<tr>
<td>INT_STATUS</td>
<td>30h</td>
</tr>
</tbody>
</table>

#### 26.9.1.14.2 Function

An interrupt is generated when the Normal Interrupt Signal Enable is enabled and at least one of the status bits is set to 1. For all bits, writing 1 to a bit clears it; writing to 0 keeps the bit unchanged. More than one status can be cleared with a single register write. For
Card Interrupt, before writing 1 to clear, it is required that the card stops asserting the interrupt, meaning that when the Card Driver services the interrupt condition, otherwise the CINT bit will be asserted again.

The table below shows the relationship between the Command Timeout Error and the Command Complete.

</tr>
</tbody>
</table>
| 22    | DEBE     | Data End Bit Error  
Occurs either when detecting 0 at the end bit position of read data, which uses the DATA line, or at the end bit position of the CRC.  
This bit will be not asserted in tuning process.  
0b - No Error  
1b - Error |
| 21    | DCE      | Data CRC Error  
Occurs when detecting a CRC error when transferring read data, which uses the DATA line, or when detecting the Write CRC status having a value other than 010.  
This bit will be not asserted in tuning process.  
0b - No Error  
1b - Error |
| 20    | DTOE     | Data Timeout Error  
Occurs when detecting one of following time-out conditions.  
- Busy time-out for R1b, R5b type  
- Busy time-out after Write CRC status  
- Read Data time-out.  
This bit will be not asserted in tuning process.  
0b - No Error  
1b - Time out |
| 19    | CIE      | Command Index Error  
Occurs if a Command Index error occurs in the command response.  
This bit will be not asserted in tuning process.  
0b - No Error  
1b - Error |
| 18    | CEBE     | Command End Bit Error  
Occurs when detecting that the end bit of a command response is 0.  
This bit will be not asserted in tuning process.  
0b - No Error  
1b - End Bit Error Generated |
| 17    | CCE      | Command CRC Error  
Command CRC Error is generated in two cases.  
- If a response is returned and the Command Timeout Error is set to 0 (indicating no time-out), this bit is set when detecting a CRC error in the command response.  
- The uSDHC detects a CMD line conflict by monitoring the CMD line when a command is issued. If the uSDHC drives the CMD line to 1, but detects 0 on the CMD line at the next SDCLK edge, then the uSDHC shall abort the command (Stop driving CMD line) and set this bit to 1. The Command Timeout Error shall also be set to 1 to distinguish CMD line conflict.  
This bit will be not asserted in tuning process.  
0b - No Error  
1b - CRC Error Generated. |

<td>Card Interrupt</td>
</tr>
<tr>
<td></td>
<td>This status bit is set when an interrupt signal is detected from the external card. In 1-bit mode, the uSDHC will detect the Card Interrupt without the SD Clock to support wakeup. In 4-bit mode, the card interrupt signal is sampled during the interrupt cycle, so the interrupt from card can only be sampled during interrupt cycle, introducing some delay between the interrupt signal from the SDIO card and the interrupt to the Host System. Writing this bit to 1 can clear this bit, but as the interrupt source from the SDIO card does not clear, this bit is set again. In order to clear this bit, it is required to reset the interrupt source from the external card followed by a writing 1 to this bit. When this status has been set, and the Host Driver needs to service this interrupt, the Card Interrupt Signal Enable in the Interrupt Signal Enable register should be 0 to stop driving the interrupt signal to the Host System. After completion of the card interrupt service (It should reset the interrupt sources in the SDIO card and the interrupt signal may not be asserted), write 1 to clear this bit, set the Card Interrupt Signal Enable to 1, and start sampling the interrupt signal again.</td>

### 26.9.1.15.2 Function

Setting the bits in this register to 1 enables the corresponding Interrupt Status to be set by the specified event. If any bit is cleared, the corresponding Interrupt Status bit is also cleared (i.e. when the bit in this register is cleared, the corresponding bit in Interrupt Status Register is always 0).

- Depending on IABG bit setting, uSDHC may be programmed to sample the card interrupt signal during the interrupt period and hold its value in the flip-flop. There will be some delays on the Card Interrupt, asserted from the card, to the time the Host System is informed.
- To detect a CMD line conflict, the Host Driver must set both Command Timeout Error Status Enable and Command CRC Error Status Enable to 1.

### 26.9.1.16 Interrupt Signal Enable (INT_SIGNAL_EN)

#### 26.9.1.16.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT_SIGNAL_EN</td>
<td>38h</td>
</tr>
</tbody>
</table>

#### 26.9.1.16.2 Function

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

### 26.9.1.17 Auto CMD12 Error Status (AUTOCMD12_ERR_STATUS)

#### 26.9.1.17.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOCMD12_ERR_STATUS</td>
<td>3Ch</td>
</tr>
</tbody>
</table>
26.9.1.17.2 Function

When the Auto CMD12 Error Status bit in the Status register is set, the Host Driver shall check this register to identify what kind of error the Auto CMD12 / CMD 23 indicated. Auto CMD23 errors are indicated in bit 04-01. This register is valid only when the Auto CMD12 Error status bit is set.

The table below shows the relationship between the Auto CMGD12 CRC Error and the Auto CMD12 Command Timeout Error.

**Table 26-12. Relationship Between Command CRC Error and Command Timeout Error for Auto CMD12**

<table>
<thead>
<tr>
<th>Auto CMD12 CRC Error</th>
<th>Auto CMD12 Timeout Error</th>
<th>Type of Error</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>No Error</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Response Timeout Error</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Response CRC Error</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>CMD line conflict</td>
</tr>
</tbody>
</table>

Changes in Auto CMD12 Error Status register can be classified in three scenarios:

1. When the uSDHC is going to issue an Auto CMD12.
   - Set bit 0 to 1 if the Auto CMD12 can't be issued due to an error in the previous command
   - Set bit 0 to 0 if the Auto CMD12 is issued
2. At the end bit of an Auto CMD12 response.
   - Check errors correspond to bits 1-4.
   - Set bits 1-4 corresponding to detected errors.
   - Clear bits 1-4 corresponding to detected errors
   - Set bit 7 to 1 if there is a command that can't be issued
   - Clear bit 7 if there is no command to issue

The timing for generating the Auto CMD12 Error and writing to the Command register are asynchronous. After that, bit 7 shall be sampled when the driver is not writing to the Command register. So it is suggested to read this register only when the AC12E bit in Interrupt Status register is set. An Auto CMD12 Error Interrupt is generated when one of the error bits (0-4) is set to 1. The Command Not Issued By Auto CMD12 Error does not generate an interrupt.

<tr>
<td></td>
<td>When std_tuning_en bit is set, this bit is used to select sampling clock to receive CMD and DATA. Otherwise, this bit is reserved. This bit is set by tuning procedure and valid after the completion of tuning(When Execute Tuning is cleared). Setting 1 means that tuning is completed successfully and setting 0 means that tuning is failed. Writing 1 to this bit is meaningless and ignored. A tuning circuit is reset by writing to 0. This bit can be cleared with setting Execute Tuning. Once the tuning circuit is reset, it will take time to complete tuning sequence. Therefore, Host Driver should keep this bit to 1 to perform re-tuning sequence to complete re-tuning sequence in a short time. Change of this bit is not allowed while the Host controller is receiving response or a read data block.</td>
</tr>
<tr>
<td>22</td>
<td>EXECUTE_TUNING Execute Tuning</td>
</tr>
<tr>
<td></td>
<td>When std_tuning_en bit is set, this bit is used to start tuning procedure. Otherwise, this bit is reserved. This bit is set to start tuning procedure and automatically cleared when running procedure is completed. The result of tuning is indicated to sam_clk_sel bit. Tuning procedure is aborted by writing 0.</td>
</tr>
<tr>
<td>21-8</td>
<td>- Reserved</td>
</tr>
<tr>
<td>7</td>
<td>CNIBAC12E Command Not Issued By Auto CMD12 Error</td>
</tr>
<tr>
<td></td>
<td>Setting this bit to 1 means CMD_wo_DAT is not executed due to an Auto CMD12 Error (D04-D01) in this register.</td>
</tr>
</tbody>
</table>

#### 26.9.1.20.2 Function

This register is used to DMA and data transfer. To prevent data loss, the software should check if data transfer is active before writing this register. These bits are DPSEL, MBSEL, DTDSEL, AC12EN, BCEN, and DMAEN.

### Field | Function
--- | ---
| | 0b - Disable  
1b - Enable |
| 1 | Block Count Enable  
This bit is used to enable the Block Count register, which is only relevant for multiple block transfers. When this bit is 0, the internal counter for block is disabled, which is useful in executing an infinite transfer.  
0b - Disable  
1b - Enable |
| 0 | DMA Enable  
This bit enables DMA functionality. If this bit is set to 1, a DMA operation shall begin when the Host Driver sets the DPSEL bit of this register. Whether the Simple DMA or the Advanced DMA is active depends on the DMA Select field of the Protocol Control register.  
0b - Disable  
1b - Enable |

#### 26.9.1.21 Force Event (FORCE_EVENT)

##### 26.9.1.21.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>FORCE_EVENT</td>
<td>50h</td>
</tr>
</tbody>
</table>

##### 26.9.1.21.2 Function

The Force Event Register is not a physically implemented register. Rather, it is an address at which the Interrupt Status Register can be written if the corresponding bit of the Interrupt Status Enable Register is set. This register is a write only register and writing 0 to it has no effect. Writing 1 to this register actually sets the corresponding bit of Interrupt Status Register. A read from this register always results in 0's. In order to change the corresponding status bits in the Interrupt Status Register, make sure to set IPGEN bit in System Control Register so that IPG_CLK is always active.

Forcing a card interrupt will generate a short pulse on the DATA1 line, and the driver may treat this interrupt as a normal interrupt. The interrupt service routine may skip polling the card interrupt factor as the interrupt is self cleared.

### 26.9.1.22 ADMA Error Status Register (ADMA_ERR_STATUS)

#### 26.9.1.22.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>ADMA_ERR_STATUS</td>
<td>54h</td>
</tr>
</tbody>
</table>
26.9.1.22.2 Function

When an ADMA Error Interrupt has occurred, the ADMA Error States field in this register holds the ADMA state and the ADMA System Address register holds the address around the error descriptor.

For recovering from this error, the Host Driver requires the ADMA state to identify the error descriptor address as follows:

- **ST_STOP**: Previous location set in the ADMA System Address register is the error descriptor address.
- **ST_FDS**: Current location set in the ADMA System Address register is the error descriptor address.
- **ST_CADR**: This state is never set because it only increments the descriptor pointer and doesn't generate an ADMA error.
- **ST_TFR**: Previous location set in the ADMA System Address register is the error descriptor address.

In case of a write operation, the Host Driver should use the ACMD22 to get the number of the written block, rather than using this information, since unwritten data may exist in the Host Controller.

The Host Controller generates the ADMA Error Interrupt when it detects invalid descriptor data (Valid=0) in the ST_FDS state. The Host Driver can distinguish this error by reading the Valid bit of the error descriptor.

<tbody>
<tr>
<td>31-2</td>
<td>ADMA System Address</td>
</tr>
<tr>
<td>ADS_ADDR</td>
<td>This register holds the word address of the executing command in the Descriptor table. At the start of ADMA, the Host Driver shall set the start address of the Descriptor table. The ADMA engine increments this register address whenever fetching a Descriptor command. When the ADMA is stopped at the Block Gap, this register indicates the address of the next executable Descriptor command. When the ADMA Error Interrupt is generated, this register shall hold the valid Descriptor address depending on the ADMA state. The lower 2 bits of this register is tied to '0' so the ADMA address is always word aligned. Since this register supports dynamic address reflecting, when TC bit is set, it automatically alters the value of internal address counter, so SW cannot change this register when TC bit is set. Such restriction is also listed in Software Restrictions.</td>

26.9.1.24.4 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>DLL_CTRL_REF_UPDATE_INT</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| DLL_CTRL_REF_UPDATE_INT | DLL control loop update interval. The interval cycle is 
\[(2 + \text{REF\_UPDATE\_INT}) \times \text{REF\_CLOCK}\]. By default, the DLL control loop shall update every two \text{REF\_CLOCK} cycles. It should be noted that increasing the reference delay-line update interval reduces the ability of the DLL to adjust to fast changes in conditions that may effect the delay (such as voltage and temperature). |
| 27-20 | DLL_CTRL_SLV_UPDATE_INT |
| Slave delay line update interval. If default 0 is used, it means 256 cycles of \text{REF\_CLOCK}. A value of 0x0f results in 15 cycles and so on. Note that software can always cause an update of the slave-delay line using the SLV\_FORCE\_UPDATE register. Note that the slave delay line will also update automatically when the reference DLL transitions to a locked state (from an un-locked state). |
| 19 | - |
| Reserved |
| 18-16 | DLL_CTRL_SLV_DLY_TARGET1 |
| Refer to DLL_CTRL_SLV_DLY_TARGET0 below. |
| 15-9 | DLL_CTRL_SLV_OVERRIDE_VAL |
| When SLV\_OVER = 1 This field is used to select 1 of 128 physical taps manually. A value of 0 selects tap 1, and a value of 0x7f selects tap 128. |
| 8 | DLL_CTRL_SLV_OVERRIDE |
| Set this bit to 1 to Enable manual override for slave delay chain using SLV\_OVER\_VAL; to set 0 to disable manual override. This feature does not require the DLL to be enabled using the ENABLE bit. In fact to reduce power, if SLV\_OVER\_VAL is used, it is recommended to disable the DLL with ENABLE = 0. |
| 7 | DLL_CTRL_GATE_UPDATE |
| Set this bit to 1 to prevent the DLL from updating (since when clock_in exists, glitches may appear during DLL updates). This bit may be used by software if such a condition occurs. Clear the bit to 0 to allow the DLL to update automatically. |
| 6-3 | DLL_CTRL_SLV_DLY_TARGET0 |
| The delay target for the uSDHC loopback read clock can be programmed in 1/16th increments of an ref\_clock half-period. The delay is \[(({\text{DLL\_CTRL\_SLV\_DLY\_TARGET1}},\text{DLL\_CTRL\_SLV\_DLY\_TARGET0}) + 1) \times \text{REF\_CLOCK} / 2) / 16\] So the input read-clock can be delayed relative input data from \((\text{REF\_CLOCK} / 2) / 16\) to \((\text{REF\_CLOCK} / 2) / 4\). |
| 2 | DLL_CTRL_SLV_FORCE_UPD |
| Setting this bit to 1, forces the slave delay line to update to the DLL calibrated value immediately. The slave delay line shall update automatically based on the SLV\_UPDATE\_INT interval or when a DLL lock condition is sensed. Subsequent forcing of the slave-line update can only occur if SLV\_FORCE\_UP is set back to 0 and then asserted again (edge triggered). Be sure to use it when uSDHC is idle. This function may not work when uSDHC is working on data / cmd / response. |
| 1 | DLL_CTRL_RESET |
| Setting this bit to 1 force a reset on DLL. This will cause the DLL to lose lock and re-calibrate to detect an REF\_CLOCK half period phase shift. This signal is used by the DLL as edge-sensitive, so in order to create a subsequent reset, RESET must be taken low and then asserted again. |
| 0 | DLL_CTRL_ENABLE |
| Set this bit to 1 to enable the DLL and delay chain; otherwise; set to 0 to bypasses DLL. Note that using the slave delay line override feature with SLV\_OVER\_VAL, the DLL does not need to be enabled. |
26.9.1.25 DLL Status (DLL_STATUS)

26.9.1.25.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>DLL_STATUS</td>
<td>64h</td>
</tr>
</tbody>
</table>

26.9.1.25.2 Function

This register contains the DLL status information. All bits are read only and will read the same as the power-reset value.

27.2 Overview

Flexible Serial Peripheral Interface (FlexSPI) host controller supports two SPI channels and up to 4 external devices. Each channel supports Single/Dual/Quad/Octal mode data transfer (1/2/4/8 bidirectional data lines).

NOTE

FlexSPI configuration is dependent on the chip configuration. Please refer to the system-level sections for boot and pinmux for chip specific information regarding the modes and number of devices supported.

27.2.1 Features

FlexSPI block supports following features:

- Flexible sequence engine (LUT table) to support various vendor devices
  - Serial NOR Flash or other device with similar SPI protocol as Serial NOR Flash
  - Serial NAND Flash
  - HyperBus device (HyperFlash/HyperRAM)
  - FPGA device
- Flash access mode
  - Single/Dual/Quad/Octal mode
  - SDR/DDR mode
  - Individual/Parallel mode
- Support sampling clock mode:
  - Internal dummy read strobe loopbacked internally
  - Internal dummy read strobe loopbacked from pad
  - Flash provided read strobe
- Memory mapped read/write access by AHB Bus
  - AHB RX Buffer implemented to reduce read latency. See the chip-specific section for AHB buffer size.
  - 16 AHB masters supported with priority for read access
• 4 flexible and configurable buffers in AHB RX Buffer
• AHB TX Buffer implemented to buffer all write data from one AHB burst. AHB TX Buffer size: 8 * 64 Bits
• All AHB masters share this AHB TX Buffer. No AHB master number limitation for Write Access.
• Software triggered Flash read/write access by IP Bus
• IP RX FIFO implemented to buffer all read data from External device. FIFO size: 16 * 64 Bits
• IP TX FIFO implemented to buffer all Write data to External device. FIFO size: 16 * 64 Bits
• DMA support to fill IP TX FIFO
• DMA support to read IP RX FIFO
• SCLK stopped when reading flash data and IP RX FIFO is full
• SCLK stopped when writing flash data and IP TX FIFO is empty

27.2.2 Block diagram

The block diagram of FlexSPI is indicated in following figure:

![FlexSPI Block Diagram](image)

Figure 27-1. FlexSPI block diagram

27.2.3 Operation Modes

This section provides information about the modes FlexSPI could be used.

• Module Disable mode

  This mode is low power mode in FlexSPI module.
In module disable mode, AHB clock and serial clock domain will be gated off internally, but IPS Bus clock is not gated off. Control and status register read/write access is available except LUT/IP RX FIFO/IP TX FIFO read/write access. Serial Flash Memory access is also not available.

This mode is entered by setting MCR0[MDIS], and exited by clearing MCR0[MDIS].

• Doze mode

This mode is low power mode in SOC system.

When the system requires FlexSPI to enter doze mode and MCR0[DOZEEN] is set, the FlexSPI will wait for all transactions to complete (STS0[ARBIDLE]=0x1) and enter doze mode. In doze mode, the AHB clock and serial clock domain will be gated off internally, but IPS Bus clock is not gated off. Control and status register read/write access is available except LUT/IP RX FIFO/IP TX FIFO read/write access. Serial Flash Memory access is also not available.

This mode is entered by system request, and exited by deasserting this system request.

• Stop mode

This mode is low power mode in SOC system.

When the system requires FlexSPI to enter stop mode, FlexSPI will wait for all transactions to complete (STS0[ARBIDLE]=0x1) and return ACK handshake to system. After ACK handshake returned, IP will gate off the AHB clock and serial clock domain internally, the system can gate the AHB Bus clock, IPS Bus clock and serial clock in system level.

This mode is entered by system stop mode request. When all command sequences finish, FlexSPI enters stop mode and returns ACK handshake. This mode is exited by deasserting system stop mode request, the ACK handshake is also deasserted immediately.

• Normal mode

In normal mode, all clocks are not gated internally. Normal register access and serial flash memory access is available.

</tbody>
</table>

27.5.2 Interrupts

This section describes all the interrupts that the FlexSPI module generates.

- **IP command done interrupt**
  
  When IP command is finished, there will be interrupt generated if INTEN[IPCMDDONEEN] is set to 0x1.

- **IP command grant error interrupt**
  
  When IP command grant timeout (not grant after MCR0[IPGRANTWAIT] * 1024 ahb clock cycles), there will be interrupt generated if INTEN[IPCMCMDGEEN] is set to 0x1.

- **AHB command grant error interrupt**
  
  When AHB command grant timeout (not grant after MCR0[AHBGRANTWAIT] * 1024 ahb clock cycles), there will be interrupt generated if INTEN[AHBCMDGEEN] is set to 0x1.

- **IP command error interrupt**
  
  When there is command check error or command execution error for IP command, there will be interrupt generated if INTEN[IPCMDERREN] is set to 0x1. Refer Overview of Error Flags for more details.

- **AHB command error interrupt**
  
  When there is command check error or command execution error for AHB command, there will be interrupt generated if INTEN[AHBCMDERREN] is set to 0x1. Refer Overview of Error Flags for more details.

- **IP RX FIFO watermark available interrupt**
When the fill level of IP RX FIFO is no less than watermark level (IPRXFCR[RXWMRK]), there will be interrupt generated if INTEN[IPRXWAEN] is set to 0x1.

- **IP TX FIFO watermark exceed interrupt**
  When the empty level of IP TX FIFO is no less than watermark level (IPTXFCR[TXWMRK]), there will be interrupt generated if INTEN[IPRXWAEN] is set to 0x1.

- **Sequence execution timeout interrupt**
  When a sequence execution time exceeds the timeout wait time (MCRI[SEQWAIT]), an interrupt will be generated if INTEN[SEQTIMEOUTEN] is set to 0x1. For example, the following flash read command sequence will lasts about 8000000 cycle (ipg_clk_sfck). If SEQWAIT is set 0xFFFF, there will be sequence timeout interrupt generated.
    - Triggered by IP command
    - Flash read data size is 0x1000000 bytes
    - Flash accessed in Single mode and SDR mode,

- **AHB Bus timeout interrupt**
  When AHB bus response timeout, there will be interrupt generated if INTEN[AHBUSTIMEOUTEN] is set to 0x1. A typical case is AHB read sequence is not configured properly in LUT (such as without READ instruction). There will never be data read from external device, then FlexSPI will never hit the read data in AHB RX Buffers for AHB Read command.

- **SCLK stopped by write command interrupt**
  When IP TX FIFO is empty during write command sequence execution, FlexSPI will stop SCLK output clock toggling and wait for write data filling. At this time, this interrupt is generated if enabled by INTEN register.

- **SCLK stopped by read command interrupt**
  When IP RX FIFO is full during read command sequence execution, FlexSPI will stop SCLK output clock toggling and wait for read data read out from IP RX FIFO. At this time, this interrupt is generated if enabled by INTEN register.

### 27.5.3 Flash Connection

There are two FlexSPI interface ports (A port and B port). Each port supports 2 flash devices by providing 2 chip select outputs.
NOTE

FlexSPI configuration is dependent on the chip configuration. See the chip-specific FlexSPI information regarding the number of devices supported.

The connection diagram with 4 devices is as following:

![Flash connection diagram with four devices](image)

**Figure 27-2. Flash connection diagram with four devices**

NOTE

- Flash A1 and A2 could be two flash chip package or two flash die on the same package. There is no difference to FlexSPI. Same for Flash B1 and B2.
- Flash A1 and B1 could be accessed in parallel, using parallel mode. FlexSPI will merge/split the flash read/program data automatically. Same for A2 and B2.
- In parallel mode, A1 and A2 could not be accessed at the same time. Same for B1 and B2.
- In individual mode, A1, A2, B1 and B2 could not be accessed at the same time. But these four device could be accessed separately.

There is a combination mode to provide octal flash support by combining A port (A_DATA[3:0]) and B port (B_DATA[3:0]) together. The connection diagram for this combination mode is as following:
27.5.4 Flash Access mode

This section describes flash access mode.

27.5.4.1 SPI clock mode

FlexSPI supports only SPI clock mode 0: Clock polarity (CPOL)=0 and Clock Phase (CPHA)=0. SCLK will stay at logic low state when SPI bus is idle.

27.5.4.2 Flash Individual mode and Parallel mode

In individual mode, Flash read/write data is received/transmit on port A or port B.
In parallel mode, Flash read/write data is received/transmit on port A and B port parallely. FlexSPI will merge/split the flash read/program data automatically. Please note that only read/program data is merged/split (READ/WRITE instruction). For other instructions (such as Command/Address/Mode/Data size), same command code/address/mode bits/data size information will be transmit to port A and port B device. For more detail, please refer to Instruction execution on SPI interface.

Individual mode and parallel mode is determined statically by register field IPCR1[IPAREN] (for IP command) or AHBCR[APAREN] (for AHB command).

### 27.5.4.3 SDR mode and DDR mode

In SDR (Single Data transfer Rate) mode, Flash receives data on SCLK rise edge and transmit data on SCLK fall edge.

In DDR (Dual Data transfer Rate) mode, Flash receives data on both SCLK rise and fall edges and transmit data on both SCLK rise and fall edges.

SDR and DDR mode is determined by instruction (opcode) in LUT sequence dynamically. There is no static configuration register field setting for SDR and DDR mode. For more details about input and output timing, please refer to FlexSPI Input Timing and FlexSPI Output Timing.

### 27.5.4.4 Single, Dual, Quad, and Octal mode

In Single mode, flash transmit/receive data on 1 Data pin (DATA0 for transmitting, DATA1 for receiving).

In Dual mode, flash transmit/receive data on 2 Data pin (DATA0~DATA1 for both transmitting and receiving).

In Quad mode, flash transmit/receive data on 4 Data pin (DATA0~DATA3 for both transmitting and receiving).

In Octal mode, flash transmit/receive data on 8 Data pin (DATA0~DATA7 for both transmitting and receiving).

Single, Dual, Quad and Octal mode is determined by instruction (num_pads) in LUT sequence dynamically. There is no static configuration register field setting for Single, Dual, Quad and Octal mode.
27.5.5 Flash memory map

Flash memory map in individual and parallel mode is as following:

![Flash memory map in individual and parallel mode](image)

Flash memory map in individual mode:
- Flash A1 address range: 0x00000000 ~ FA1_SIZE
- Flash A2 address range: FA1_SIZE ~ (FA1_SIZE + FA2_SIZE)
- Flash B1 address range: (FA1_SIZE + FA2_SIZE) ~ (FA1_SIZE + FA2_SIZE + FB1_SIZE)
- Flash B2 address range: FA1_SIZE + FA2_SIZE + FB1_SIZE) ~ (FA1_SIZE + FA2_SIZE + FB1_SIZE + FB2_SIZE)

Flash memory map in parallel mode:
- Flash A1+B1 address range: 0x00000000 ~ FA1_SIZE*2
- Flash A2+B2 address range: FA1_SIZE*2 ~ (FA1_SIZE*2 + FA2_SIZE*2)

**NOTE**
- When MCR2[SAMEDEVICEEN] is set to 0x1, FA1_SIZE/FA2_SIZE/FB1_SIZE/FB2_SIZE = FLSHA1CR0[FLSHSZ] * 1KByte
- When MCR2[SAMEDEVICEEN] is set to 0x0, FA1_SIZE = FLSHA1CR0[FLSHSZ] * 1KByte; FA2_SIZE = FLSHA2CR0[FLSHSZ] * 1KByte; FB1_SIZE = FLSHB1CR0[FLSHSZ] * 1KByte; FB2_SIZE = FLSHB2CR0[FLSHSZ] * 1KByte
- Flash B1/B2 size setting are ignored in parallel mode (FLSB1CR0[FLSHSZ], FLSHB2CR0[FLSHSZ]). To
support parallel mode application, Flash B1 should be same device as A1 and Flash B2 should be same device as A2.

### 27.5.6 Flash address sent to Device

Flash access start address is determined by AHB address (AHB command) or IPCR0[SFAR] register (IP command). Refer Flash access by AHB Command and Flash access by IP Command for more details.

For AHB command, FlexSPI controller will remove flash base address automatically when sending flash address to devices. For IP command, the address in IPCR0[SFAR] should be the flash device’s address without base address. Flash address is sent to devices in two part: Row Address and Column Address. For flash devices not supporting Column address, please set register field FLSHxCR1[CAS] to 0. Then all flash address bits will be sent to Flash device as Row address. For flash device supporting word-addressable feature, the last bit of flash address is not needed because flash is read/programmed in terms of 2 bytes. For parallel mode, Flash A1/B1 (or A2/B2) is accessed parallely, so the flash address sent to flash device should be divided by 2. Following table indicates the relationship of Row/Column Address and flash address (FA)

<table>
<thead>
<tr>
<th>Parallel mode</th>
<th>Word-addressable</th>
<th>Row Address</th>
<th>Column Address</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>FA[31:Cas]</td>
<td>FA[CAS-1:0]</td>
<td>There is no limitation on FA and data size alignment.</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>FA[31:Cas+1]</td>
<td>FA[CAS:1]</td>
<td>FA and data size should be 2 byte aligned.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>FA[31:Cas+1]</td>
<td>FA[CAS:1]</td>
<td>FA and data size should be 2 byte aligned.</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>FA[31:Cas+2]</td>
<td>FA[CAS+1:2]</td>
<td>FA and data size should be 4 byte aligned.</td>
</tr>
</tbody>
</table>

**NOTE**

- FA is the flash address with flash base address removed.
- If the Row/Column Flash Address bit number to be sent to Flash device defined in Instructions is more than valid Row/Column Flash Address bit number, high position bits will be supplemented with zero. Refer Programmable Sequence Engine for more details about Row/Column Address instruction.
When parallel mode enabled or word-addressable flash used, there is limitation on flash start address and data size. This requirement could be meet by aligning AHB bus access address (For AHB command) or IP command address IPCR0[SFAR] (For IP command) in software. There are two ways to avoid these limitation in specified case.

1. For **AHB Read Command** only:

   When AHBCR[READADDROPT] and AHBCR[PREFETCHEN] are both set to 1, FlexSPI will guarantee flash access start address and data size are 64 bit aligned by hardware.

   When AHBCR[READADDROPT] is set to 1, FlexSPI will fetch redundant data to guarantee flash start address aligned with 8 bytes. When prefetch enabled (AHBCR[PREFETCHEN] is set to 1), flash read data size is determined by AHB RX Buffer size which is 64 bit aligned.

2. For **AHB Write Command and Individual mode** only:

   By default, FlexSPI will guarantee flash write access start address and data size are 16 bit aligned by using DQS as write mask.

   This feature is not applied in parallel mode and should be used only if external device supports write mask feature.

### 27.5.7 Look Up Table

The LUT (Look Up Table) is an internal memory to preserve a number of pre-programmed sequences. Each sequence consists of up to 8 instructions which are executed sequentially. When a flash access is triggered by an IP command or an AHB command, FlexSPI controller will fetch the sequence from LUT according to sequence index/number and execute it to generate a valid flash transaction on SPI interface.

Following figure indicates the structure of LUT, sequence and instruction.
NOTE

If the instruction number needed is less than 8 for a flash transaction, STOP instruction should be programmed for the unneeded instructions (instruction code 8'h00).

For IP command and AHB write command, FlexSPI controller always executes from instruction pointer 0. For AHB read command, FlexSPI controller executes from a saved instruction start pointer. FlexSPI controller saves the instruction start pointers separately for each flash device. All these saved instruction pointer are zero before JMP_ON_CS instruction is executed,. When JMP_ON_CS instruction is executed, the operand in JMP_ON_CS instruction will be saved as instruction start pointer. Refer XIP Enhanced Mode for more details.

The reset value of LUT is unknown because it is implemented as internal memory. LUT should be programmed according to the device connected on board. In order to protect its contents during a code runover, the LUT could be locked/unlocked to avoid change by mistake after programmed. The key for locking or unlocking the LUT is 0x5AF05AF0. The process for locking and unlocking the LUT is as follows:

Locking the LUT

1. Write the key (0x5AF05AF0) in to the LUT Key Register (LUTKEY).
2. Write 1b1 to LUTCR[LOCK] and 1b0 to LUTCR[UNLOCK] fields of the LUT Control Register, immediately after the above KEY register writing. LUT is not
successfully locked if there is any other register write access to FlexSPI between these two write accesses.

Unlocking the LUT

1. Write the key (0x5AF05AF0) in to the LUT Key Register (LUTKEY).
2. Write 1b0 to LUTCR[LOCK] and 1b1 to LUTCR[UNLOCK] fields of the LUT Control Register, immediately after the above KEY register writing. LUT is not successfully unlocked if there is any other register write access to FlexSPI between these two write accesses.

The lock status of the LUT can be read from register field LUTCR[LOCK] and LUTCR[UNLOCK].

27.5.8 Programmable Sequence Engine

FlexSPI controller implements a programmable sequence engine that executes the sequence from LUT. FlexSPI controller executes the instructions sequentially and generates flash transaction on the SPI interface accordingly. The following table is a complete list of the supported instructions.

<table>
<thead>
<tr>
<th>Name</th>
<th>Opcode</th>
<th>Num_pads</th>

The programmable sequence engine allows the software to configure the FlexSPI LUT according to external serial device connected on board. The flexible structure is easily adaptable to new command/protocol changes from different vendors.

DDR sequence is a flash access sequence that contain DDR instruction which is not DUMMY, it may contain SDR instructions optionally. SDR sequence is a flash access sequence that don't contain any DDR instruction. FlexSPI controller determines instruction SDR or DDR mode by decoding bit 5 of instruction opcode. The output/input timing on FlexSPI is different for SDR and DDR sequences. Especially note that SDR instruction in SDR sequence and DDR sequence is executed differently. Refer FlexSPI Input Timing and FlexSPI Output Timing for more details.

27.5.8.1 Instruction execution on SPI interface

This section describes the detail of instruction execution on SPI interface. For all instructions transmitting/receiving data bits to/from flash, the bit order in one byte is higher on DATA3 than DATA0, and higher on B port than A port.

1. Command Instruction

Command Instruction (CMD_SDR/CMD_DDR) is normally used to transmit command code to external flash device. Command code is the 8 bits operand in instruction. Command code will be send to both B port and A port in parallel mode. Refer Flash access sequence example for examples.

2. Address Instruction

Address Instructions (RADDR_SDR/RADDR_DDR/CADDR_SDR/CADDR_DDR) are normally used to send Flash access start address (Row/Column Address) to external flash device. Row/Column Address bits are determined by FlexSPI according to AHB access address or IP command address. Refer Flash address sent to Device for more details. The bit number is the operand value in instruction code. Row/Column address bits will be send to both B port and A port in parallel mode. For memories that read the flash address on 4 SCK edges, the sum of CADDR +RADDR must be 32. Otherwise, the FlexSPI will not generate 4 SCK edges of address phase. Refer Flash access sequence example for examples.

3. Mode Instruction

Mode Instructions (MODEx_SDR/MODEx_DDR) are normally used to send mode bits to external flash device. Mode bits are the (lower) bits value of the instruction operand. The transition bit number is 1 for MODE1_SDR/MODE1_DDR, 2 for MODE2_SDR/MODE2_DDR, 4 for MODE4_SDR/MODE4_DDR and 8 for MODE8_SDR/MODE8_DDR. Note that pad number should be no more than mode
bit number. For example, it is not allowed to set num_pads to 2'b11 (Octal mode) for MODE4_* instructions. Mode bits will be send to both B port and A port in parallel mode. Refer Flash access sequence example for examples.

4. **Data Size Instruction**

Data Size Instructions (DATSZ_SDR/DATSZ_DDR) are used to send program/read data size (byte number) to external device. This instruction is normally used in FPGA application when the memory space in external device acts similar as a FIFO. The device needs data size information to determine how much data will be popped from or pushed into internal FIFO. The bit number is the operation value in the instruction. Data size bits will be send to both B port and A port in parallel mode. Refer Flash access sequence example for examples.

5. **Write Instruction**

Write Instructions (WRITE_SDR/WRITE_DDR) are normally used to send program data to external device. Programming data are fetched from IP TX FIFO (IP Command) or AHB TX Buffer (AHB command). For more details about flash program data size, refer Flash access by AHB Command and Flash access by IP Command. The byte order for programming date is always from low to high. Odd bytes are send on A port and Even bytes are send on B port in parallel mode. Refer Flash access sequence example for examples.

6. **Read Instruction**

Read Instructions (READ_SDR/READ_DDR) are normally used to receive flash data from external device. Received data will be put into IP RX FIFO (IP Command) or AHB RX Buffer (AHB command). For more detail about flash read data size, refer Flash access by AHB Command and Flash access by IP Command. The byte order for reading date is always from low to high. Odd bytes are received from A port and Even bytes are received from B port in parallel mode. Refer Flash access sequence example for examples.

7. **Dummy Instruction**

Dummy Instructions (DUMMY_SDR/DUMMY_DDR/DUMMY_RWDS_SDR/ DUMMY_RWDS_DDR) are used to provide turnaround cycles on SPI interface. During dummy instruction, neither FlexSPI controller nor external device drives SPI interface. Refer Programmable Sequence Engine for more details about dummy cycle number.
DUMMY_RWDS_DDR could be used for HyperBus device which use "RWDS" pin to indicate whether extra latency count needed. DUMMY_RWDS_SDR is reserved for future. FlexSPI controller checks DQS pin input level at the 4th cycle after SCLK output toggling is enabled. DQS pins is called "RWDS" in HyperBus specification. Refer Flash access sequence example for examples.

NOTE
The FlexSPI releases the bus after at least one cycle. Therefore, to avoid data contention, number of dummy lines should be programmed more than 1 if data is transferred on more than 1 line.

27.5.8.2 Flash access sequence example

Following is an example for SDR single I/O Read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.

![Flash access sequence example](image)

**Figure 27-6. Flash access sequence example (SDR Single I/O Read sequence)**

NOTE
- FlexSPI dummy instruction starts and ends at serial root clock rise edge.
- Device dummy cycle starts and ends at SCLK fall edge (on Cypress S25FS512S datasheet).

Following is an example for SDR Quad I/O Read sequence (Cypress Serial Nor Flash S25FS512S) in individual mode.
Figure 27-7. Flash access sequence example (SDR Quad I/O Read sequence)

NOTE

- FlexSPI dummy instruction starts and ends at serial root clock rise edge.
- Device dummy cycle starts and ends at SCLK fall edge (on Cypress S25FS512S datasheet).

Following is an example for DDR Quad I/O Read sequence (Cypress Serial Nor Flash S25FS512S) in parallel mode.
Figure 27-8. Flash access sequence example (DDR Quad I/O Read sequence)

Following is an example for HyperBus device read transaction (Single latency count) in individual mode.
Figure 27-9. HyperBus device read transaction with single latency count

Following is an example for HyperBus device read transaction (Additional latency count) in individual mode.

Figure 27-10. HyperBus device read transaction with additional latency count
Following is an example for HyperBus device write transaction (Single latency count) in individual mode.

Figure 27-11. HyperBus device write transaction with single latency count

Following is an example for HyperBus device write transaction (Additional latency count) in individual mode.
27.5.9 Flash access by IP Command

Flash access could be triggered by IP command in following steps.

- Fill IP TX FIFO with programming data if this is a programming command (programming flash data, flash status registers etc.)
- Set flash access start address (IPCR0[SFAR]), read/program data size, sequence index in LUT and sequence number (IPCR1[ISEQNUM]).
- Trigger flash access command by writing 1 to register bit IPCMD[TRG]
- Polling register bit INTR[IPCMDDONE] to wait for this IP command to finish on FlexSPI interface.

**NOTE**

- IP TX FIFO could be filled before or after writing IPCR0/IPCR1/IPCMD register. If SFM command is started with IP TX FIFO empty, FlexSPI will stop SCLK toggling to wait for TX data ready automatically.
- IPCMD register must be written after writing IPCR0/IPCR1 register.
• Multiple Command sequences (8 at most) could be issued by one IP command.
• It is not allowed to issue another IP command before the previous IP command is finished. The behaviour is unknown in this case.

If this is a Reading command to Serial Flash Memory, all reading data from Flash will be put into IP RX FIFO. Software will need to read out data from IP RX FIFO by AHB bus or IP Bus. When IP RX FIFO is full and there is more data to be read from Flash device, FlexSPI will stop SCLK output clock toggling until IP RX FIFO is not full. Please refer to SCLK stop feature for more detail.

The detail of triggered Serial Flash Command is as following:

• Flash access start address:
  Determined by register field IPCR0[SFAR]

• Flash Chip Select:
  Determined by flash access address and Flash size setting (FLSHxCR0[FLSHSZ]).

• Flash command Sequence Index and Sequence Number:
  The sequences indexed from IPCR1[ISEQID] to (IPCR1[ISEQID] + IPCR1[ISEQNUM]) in LUT will be executed by FlexSPI sequentially.

• Flash Individual/Parallel access mode
  Determined by IPCR1[IPAREN].

• Flash Read/Program Data Size:
  • If IPCR1[IDATSZ] value is non-zero, flash read/program data size (in byte) is IPCR1[IDATSZ].
  • If IPCR1[IDATSZ] value is zero, flash read/program data size (in byte) will the operand value in the READ/WRITE instruction.

**NOTE**
• Software should make sure the last sequence index never exceeds the LUT sequence number (IPCR1[ISEQID] + IPCR1[ISEQNUM] < 16).
• Data size is applied to every command sequence if sequence number is more than one.
• Data size is ignored if there is no WRITE/READ instruction in the command sequence.
IP command request is sent to arbitrator after triggered by software. It is not executed on FlexSPI Interface until granted by arbitrator. Please refer to Command Arbitration for more details.

### 27.5.9.1 Reading Data from IP RX FIFO

FlexSPI put the read data from external device into IP RX FIFO for IP command. These data could be read out by following two memory space access.

- 0x100 - 0x180 (by IPS Bus)
- 0x7FC00000 - 0x7FC00080 (by AHB Bus)

If MCR0[ARDFEN] is set to 0x1, read data in IP RX FIFO could only be read out by AHB Bus, IP Bus read access to IP RX FIFO will always return with data zero and no bus error occur.

If MCR0[ARDFEN] is set to 0x0, read data in IP RX FIFO could only be read out by IPS Bus, AHB Bus read access to IP RX FIFO will trigger bus error.

FlexSPI push read data into IP RX FIFO in terms of 64 bits every time it receives 64 bits data from external device. When read data bits number is not 64 bits aligned, FlexSPI will push additional zero bits into IP RX FIFO for the last push.

IP RX FIFO could be read by processor or DMA. Following is the detail flow for processor and DMA reading:

1. **Reading by processor**

   To read by processor, following register settings are needed:
   
   - Set register field IPRXFCSR[RXDMAEN] to 0.
   - Set watermark level by IPRXFCSR[RXWMRK], watermark level is (IPRXFCR[RXWMRK]+1)*8 bytes.
   - Set register field INTEN[IPRXWAEN] to enable IP RX FIFO watermark available interrupt (optional).

   Processor needs to poll register INTR[IPRXWA] or wait for IP RX FIFO Watermark Available interrupt before reading IP RX FIFO. This is to make sure there is a watermark level Data filled in IP RX FIFO before reading.

   After reading a watermark level data from IP RX FIFO, software need to set register bit INTR[IPRXWA]. This set action will pop out a watermark level data from IP RX FIFO.

   Following digram indicates the reading flow from IP RX FIFO by processor.
Figure 27-13. Reading IP RX FIFO by processor

**NOTE**

- Processor need to read out a watermark level data from IP RX FIFO each time before set register bit INTR[IPRXWA].
- It's supported that the total flash read/program data size is not multiple of watermark level. In this case, the reading data size from IP RX FIFO will be less than a watermark level for the last time, software should poll IPRXSTS[FILL] field instead of polling INTR[IPRXWA]. After copying all the data from IP RX FIFO and all command sequences to Flash are finished (INTR[IPCMDDONE]=1), software should clear IP RX FIFO by setting IPRXFCR[CLRIPRXF]. Otherwise, the reading data will be wrong for the next reading command to Flash.
- IP RX FIFO data is not popped out by each reading access to IP RX FIFO, but popped by writing 0x1 to register INTR[IPRXWA] bit.

2. **Reading by DMA**

To read IP RX FIFO by DMA, following setting is needed:

- Set register field IPRXFCR[RXDMAEN] to 1.
- Set watermark level by IPRXFCR[RXWMRK], watermark level is (IPRXFCR[RXWMRK]+1)*8 bytes.
- Set DMA transfer Minor loop size to same watermark level.
Figure 27-14. Reading from IP RX FIFO by DMA

NOTE

• DMA request is generated when the fill level of IP RX FIFO is higher than (or equal) watermark level. This request is not pulse valid but level valid.
• DMA should read out watermark level data from IP RX FIFO each time (set minor loop size with the same value as watermark level).
• DMA need to return a Done handshake (pulse valid) to FlexSPI each time it finished reading a watermark level data.
• IP RX FIFO data is not popped out by each reading access, but popped by DMA done handshake.
• It is not supported that the total read/write data size (Major loop size) is not multiple of watermark level. Because the DMA does not know when the data is ready for the last reading. It makes the DMA driver too complex to poll IPRXFSTS [FILL] field.

27.5.9.2  Filling Data to IP TX FIFO

The programming should be put into IP TX FIFO and then transmit to Flash by FlexSPI. It could be filled by two memory space.

• 0x180 - 0x200 (by IP Bus)
• 0x7F800000 - 0x7F800080 (by AHB Bus)
To fill by AHB Bus, need to set MCR0[ATDFEN] to 1, IP Bus write access to IP TX FIFO will be ignored, but no bus error.

To fill by IP Bus, need to set MCR0[ATDFEN] to 0, AHB Bus write access to IP TX FIFO will return Bus Error.

IP TX FIFO is popped with 64 bits data every time FlexSPI fetch data for transmitting. If the programming data size is not multiple of 64 bits, last popped valid bits will be less than 64 bits. But there is no problem because these invalid bits are not transmitted to Flash at all.

IP TX FIFO could be filled by processor or DMA.

To fill by processor, need following setting:

- Set register field IPTXFCR[TXDMAEN] to 0.
- Set watermark level by IPTXFCR[TXWMRK], watermark level is (IPTXFCR[TXWMRK]+1)*8 bytes.
- Set register field INTEN[IPTXWEEN] to enable IP TX FIFO watermark empty interrupt (optional).

Processor needs to poll register INTR[IPTXWE] or wait for IP TX FIFO Watermark empty interrupt before filling IP TX FIFO. This is to make sure there is enough space for a watermark level Data filling before filling.

After filling a watermark level data to IP TX FIFO, need to set register bit INTR[IPTXWE]. This will push a watermark level data into IP TX FIFO (write pointer is incremented).

**NOTE**

IP TX FIFO data is not pushed by each write access, only pushed by set INTR[IPTXWE] bit.

Following diagram indicates the filling flow to IP TX FIFO by processor.
Figure 27-15. Filling IP TX FIFO by processor

NOTE

- Processor will need to fill a watermark level data to IP TX FIFO each time.
- It's allowed that total write data size is not multiple of watermark level. In this case, the writing size will be less than a watermark level for the last time. After filling all data into IP TX FIFO and all Command Sequences to Flash are finished (INTR[IPCMDDONE]=1), processor should clear IP TX FIFO by setting IPTXFCR[CLRIPTXF]. Otherwise, the programming data will be wrong for the next programming Command to Flash.

To fill IP TX FIFO by DMA, need following setting:

- Set register field IPTXFCR[TXDMAEN] to 1.
- Set watermark level by IPTXFCR[TXWMRK], watermark level is (IPTXFCR[TXWMRK]+1)*8 bytes.
- Set DMA transfer Minor loop size to same watermark level.
NOTE

- DMA request is generated when there is empty space more than watermark level in IP TX FIFO. This request is not pulse valid but level valid.
- DMA should fill watermark level data into IP TX FIFO each time (set minor loop size with the same value as watermark level.
- DMA need to return a Done handshake (pulse valid) to FlexSPI each time it finished filling a watermark level data.
- IP TX FIFO data is not pushed in by each reading access, but pushed by DMA done handshake.
- It's allowed that total program data size (Major loop size) is not multiple of watermark level. After filling all data into IP TXFIFO and all command sequences to Flash are finished (INTR[IPCMDDONE]=1), need to clear IP TX FIFO by setting IPTXFCR[CLRIPTXF]. Otherwise, the programming data will be wrong for the next programming Command to Flash.

27.5.10  Flash access by AHB Command

Flash could be accessed by AHB bus directly on AHB address space: 60000000~0x80000000. This address space is mapped to Serial Flash Memory in FlexSPI. AHB bus access to this address space may trigger Flash access command sequence as needed.
For AHB read access to Serial Flash Memory, FlexSPI will fetch data from flash into AHB RX Buffers and then return the data on AHB Bus. For AHB write access to Serial Flash Memory, FlexSPI will buffer AHB Bus write data into AHB TX Buffer and then transmit to Serial Flash memory.

There is no software configuration or polling need for AHB command except FlexSPI initialization. AHB master access external flash device transparently similar as normal AHB slave.

AHB command is normally used to access serial Flash memory space. IP command should be used to access the control and status registers or other spaces such as OTP in external flash device.

Following section described AHB command for read and write in more detail.

**NOTE**

When FlexSPI controller return AHB bus error for SFM access, AHB master should stop following access beats in current burst.

### 27.5.10.1 AHB write access to Flash

For AHB write access to Flash, FlexSPI will buffer the write data from AHB bus into internal AHB TX Buffer and then transmit them to Flash. FlexSPI only buffers write data for one AHB burst. Following diagram indicates the hardware operation in response to AHB write access to Flash.
Functional description

Figure 27-17. Hardware operation in response to AHB write access to Flash

FlexSPI triggers new AHB write command in following cases:

- This beat is the last one in current AHB burst (any burst type except INCR).
- AHB TX Buffer is full after buffering current beat data.
- AHB bus becomes IDLE or a new burst comes with AHB TX Buffer not empty.

The detail information about the triggered AHB write command:

- Flash Access Start Address:
  Determined by AHB burst address. FlexSPI will record the start address for the data in AHB TX Buffer and this address will be used as flash access start address
- Flash Chip Select:
FlexSPI determined the chip selection by flash access start address and flash size
setting.

- Flash Command Sequence Index:
  Determined by FLSHxCR2[AWRSEQID].

- Flash Command Sequence Number:
  Determined by FLSHxCR2[AWRSEQNUM]. If AWRSEQNUM is not zero,
  multiple flash access command sequences will be triggered every time for AHB write
  command. The sequences indexed from AWRSEQID to (AWRSEQID +
  AWRSEQNUM) in LUT will be executed sequentially.

- Flash access mode (Individual/Parallel)
  Determined by AHBCR[APAREN].

- Flash Data Size:
  Determined by byte number of buffered data in AHB TX Buffer.

Following examples indicates internal logic for AHB write access to Flash. In these
examples, AHB_TX_BUF is 64 Bytes (8*64bits).

- AHB INCR/64bit/Bufferable burst with address sequence 0x8, 0x10, 0x18, 0x20, ..., 0x50 (10 beat totally):

  Two AHB write command will be triggered: the first command with flash start
  address 0x8 and data size 0x40; the second command with flash start address 0x48
  and data size 0x10. See Figure 27-18.
**Functional description**

![Diagram of AHB write access (INCR/64bit/Bufferable)](image)

- AHB WRAP8/64bit/Bufferable burst with address sequence 0x28, 0x30, 0x38, 0x0, 0x8, 0x10, 0x18, 0x20:

  One AHB write command will be triggered with flash start address 0x0 and data size 0x40. See Figure 27-19.

---

**Figure 27-18. AHB write access (INCR/64bit/Bufferable)**
Figure 27-19. AHB write access (WRAP8/64bit/Bufferable)

- AHB WRAP8/64bit/Non-bufferable burst with address sequence 0x28, 0x30, 0x38, 0x0, 0x8, 0x10, 0x18, 0x20:

  One AHB write command will be triggered with flash start address 0x0 and data size 0x40;
Figure 27-20. AHB write access (WRAP8/64bit/Non-Bufferable)

NOTE
The wrapper burst is not supported if burst data size (in byte) is larger than AHB TX Buffer size (in byte). For example, if AHB_TX_BUF is 64 Bytes (8*64bits), AHB WRAP16 * 64bit writet burst access is not supported.

27.5.10.2 AHB read access to Flash

For AHB read access to Flash, FlexSPI will check whether hit AHB TX Buffer/AHB RX Buffer/pending AHB read command according to the burst access type and register setting. If all these miss, FlexSPI trigger a new AHB read command to fetch data from Flash. Following diagram indicates the hardware operation in response to AHB read access to Flash.
Figure 27-21. Hardware operation in response to AHB read access to Flash

**NOTE**

1. AHB prefetch is enabled when both
   - AHBCR[PREFETCHEN]=0x1 and
   - AHBRXBUFxCR0[PREFETCHEN]=0x1 (x is the ahb rx buffer ID for current AHB master).
2. AHB RX Buffer holds the data read from Flash. This data may become incoherent if the AHB writes to the same flash address.

The detail information about the triggered AHB read command:

- Flash Access Start Address and Data Size:
Determined by AHB address, burst type and burst size. FlexSPI will fetch read data from the start address for current burst or beat.

### Table 27-8. AHB read command flash start address and data size

<td>hbeat_start_address</td>
<td>(flash_top_address - hbeat_start_address)</td>
</tr>
<tr>
<td></td>
<td>Yes</td>
<td>WRAP4/WRAP8/WRAP16</td>
<td>hburst_start_address</td>
<td>(flash_top_address - hburst_start_address)</td>
</tr>
</tbody>
</table>

**NOTE**

- hbeat_start_address is HADDR input from AHB master for current beat.
- hburst_start_address (for e.g. 0x00) is the lowest address for current burst; hburst_end_address (for e.g. 0x10) is the highest address in current burst plus 1. For example, WRAP4 burst with HADDR 0x8,0xC, 0x0, 0x4.
• ahb_rx_buf_sz is the buffer size in byte of AHB RX Buffer which is used by current master.

• flash_top_address is the top address of currently accessed flash.

• Flash Chip Select:
  FlexSPI determined the chip selection by flash access start address and flash size setting.

• Flash Command Sequence Index:
  Determined by FLSHxCR2[ARDSEQID].

• Flash Command Sequence Number:
  Determined by FLSHxCR2[ARDSEQNUM]. If ARDSEQNUM is not zero, multiple flash access command sequences will be triggered every time for AHB read command. The sequences indexed from ARDSEQID to (ARDSEQID + ARDSEQNUM) in LUT will be executed sequentially.

• Flash access mode (Individual/Parallel):
  Determined by AHBCR[APAREN].

  **NOTE**
  • FlexSPI determines which ARDSEQNUM/ARDSEQID fields will be used as sequence ID by flash device chip selection automatically. See MCR2[SAMEDEVICEEN] for more details.
  • FlexSPI determines which AHB RX Buffer used for current AHB read access by master ID. For more details about the AHB RX buffer ID and AHB master ID mapping, see AHB RX Buffer Management.
  • It is not allowed to allocate AHB RX Buffer less than AHB Burst size. The behaviour is unknown for this case.

### 27.5.10.3 AHB RX Buffer Management

There are 4 buffers (Buffer 0 - Buffer 3) in AHB RX Buffer, which are transparent to AHB masters. FlexSPI fetch flash data and return on AHB Bus automatically. There is no status register polling needed for AHB read access to Serial Flash Memory.
See the chip-specific section for AHB buffer size. The buffer size is flexibly configurable for each buffer in AHB RX Buffers by register fields AHBRXBUF0CR0[BUFSZ]~AHBRXBUF6CR0[BUFSZ]. The buffer size for Buffer 0 to Buffer 3 could be set 0. If the buffer size is set to 0x0, the related MSTRID field setting (in same AHBRXBUFxCR0 register) is ignored by FlexSPI. Buffer 3 is used for all AHB masters which is not assigned to Buffer 0 - Buffer 2. Buffer 3 size setting field (AHBRXBUF3CR0[BUFSZ]) is ignored by FlexSPI, its buffer size is: AHB RX Buffer total size - sum of (Buffer 0 - Buffer 2 size).

When there is AHB read access to Serial Flash Memory, FlexSPI determines which AHB RX Buffer to use as following:

1. If master ID equal AHBRXBUF0CR0[MSTRID] and AHBRXBUF0CR0[BUFSZ] is not zero, Buffer 0 will be used.
2. If master ID equal AHBRXBUF1CR0[MSTRID] and AHBRXBUF1CR0[BUFSZ] is not zero, Buffer 1 will be used.
3. If master ID equal AHBRXBUF2CR0[MSTRID] and AHBRXBUF2CR0[BUFSZ] is not zero, Buffer 2 will be used.
4. If all above case not meet, Buffer 3 will be used

**NOTE**

- Software should make sure the buffer size of each buffer is no less than the max burst size of AHB Read access from the master using this buffer. Otherwise the behaviour is undefined.
- It is not supported to assign multiple buffers for single AHB master.
- When AHB read prefetch is enabled (AHBCR[PREFETCHEN] is set), the prefetch data size will be determined by buffer size. FlexSPI will fetch data from external Flash with buffer size if no flash boundary across.
- AHB master priority setting (register field AHBRXBUFxCR0[PRIORITY] is used only for the suspending control of AHB prefetching. See Command Abort and Suspend.

### 27.5.11 Command Arbitration

There are four Flash access command sources:

1. AHB Command (triggered by AHB Write access to SFM space)
2. AHB Command (triggered by AHB Read access to SFM space)
3. IP command (triggered by writing IPCMD[TRG])
4. Suspended command (AHB Read prefetch sequence which is suspended)

**NOTE**
- An AHB bus access never triggers a write command and a read command at the same time.
- AHB prefetch sequence is an AHB Command sequence triggered by AHB Read access when AHB prefetch is enabled. After all read data fetched for current AHB read burst, FlexSPI will prefetch more data to reduce the read latency for next AHB read access. AHB command for read is never aborted while fetching read data for current AHB read burst. But AHB read command could be aborted by any new IP command or AHB command request when it's prefetching data (not for current read burst).

The granted priority of these 4 command source is as following when Arbitrator is idle (STS0[ARBIDLE]=1):

1. AHB command (Read/Write)
2. IP Command
3. Suspended Command

**NOTE**
Suspended command is not granted immediately when arbitrator is idle and no AHB/IP command request. Arbitrator will wait for n AHB clock cycle idle state before resuming the suspended command (n is the register field value in MCR2[RESUMEWAIT]). This intend to avoid AHB prefetch sequence being resumed and suspended frequently.

All command request are not granted if Arbitrator is busy in executing AHB/IP command (not suspended command), and there will AHB/IP Command granted error if the grant is timeout.

If new AHB/IP command request comes while Arbitrator is executing AHB read prefetch sequence, AHB read prefetch sequence will be aborted (but not immediately). Arbitrator will grant AHB/IP command request after AHB read prefetch sequence is aborted on FlexSPI interface and saved all internal data pointers.
27.5.11.1  Command Abort and Suspend

This section describes command abort and suspend mechanism.

1. **Command Abort**
   
   As mentioned above, AHB read prefetch sequence could be aborted if new AHB/IP command request comes.

2. **Command Suspend**
   
   When AHB read prefetch sequence is aborted on FlexSPI interface, FlexSPI will save this suspended sequence in following cases and resume this sequence if arbitrator is idle for enough time:
   
   - There is no valid suspended command (Register field AHBSNDSTS[ACTIVE] is 0x0). This is possible if there is no suspended command yet or suspended command is resumed.
   - Aborted AHB read prefetch sequence is higher priority than current active suspend sequence.

   **NOTE**
   
   Original suspended sequence will be ignored and never resumed by FlexSPI.

3. **Suspended Command**
   
   The suspended command (internal status) turns active when there is any AHB prefetch command aborted and suspended. It turns inactive in following cases:
   
   - Suspended command is resumed by Arbitrator.
   - There is a new AHB read command request and it's triggered by AHB master using the same AHB RX Buffer (Buffer ID).

   **NOTE**
   
   - MCR0[SWRESET] can be used to clear any suspended command. It means saved suspended command will be dropped and no more resume will happen. Clearing suspended command is needed after flash page program/erase or any other command may lead period of time that flash can not support read command.

Following is an example indicating command abort/suspend/resume flow:
27.5.12 SCLK stop feature

FlexSPI will stop SCLK output toggling when programming data is not ready for programming command sequence or there is no space (in internal FIFO) to receive data for reading command sequence.

There may be certain devices that do not support SCLK stopped during command sequence (chip select is valid). SCLK stopping could be avoid as following:

- For flash reading triggered by IP command
  - Never trigger a read command with data size larger than IP RX FIFO size.
  - Internal async FIFO for flash reading should never be full.

  FlexSPI pop data from this async FIFO in 64 bits per AHB clock cycle, and receiving data from FlexSPI interface in serial root clock. The receiving speed is determined by Flash access mode (Single/Dual/Quad/Octal mode and Individual/Parallel mode). For example, in Octal mode and Parallel mode, FlexSPI receives 16 bits per serial root clock cycle. This async FIFO is never full if AHB clock frequency is higher than 1/4 of serial root clock.

- For flash programming triggered by IP command
  - Never trigger a program command with data size larger than IP TX FIFO size.
  - Fill all programming data into IP TX FIFO before trigger the IP command.
  - Internal async FIFO for flash programming should never be empty

  FlexSPI fetch programming data into this async FIFO in 64 bits per AHB clock cycle, and transmitting data to FlexSPI interface in serial root clock. The transmitting speed is determined by Flash access mode (Single/Dual/Quad/Octal mode and Individual/Parallel mode). For example, in Octal mode and Parallel mode, FlexSPI transmits 16 bits per serial root clock cycle. This async FIFO is never empty if AHB clock frequency is higher than 1/4 of serial root clock.

- For flash reading/programming triggered by AHB command
- Internal async FIFO for flash reading/programming should never be full/empty. The frequency ratio limitation is same as flash reading/programming triggered by IP command.

**NOTE**
- FlexSPI never trigger a AHB read command with data size larger than internal AHB RX buffer size.
- FlexSPI never trigger a AHB program command with data size larger than internal AHB TX buffer size.
- All programming data is buffered into AHB TX Buffer before triggering AHB program command in FlexSPI.

### 27.5.13 FlexSPI Output Timing

This section describes the output timing in FlexSPI.

#### 27.5.13.1 Output timing between Data and SCLK

This section describes the output timing relationship of data (on A_DATA/B_DATA) and SCLK. There are three cases for the data output timing:

- **SDR instruction in SDR sequence**
  SDR sequence is the sequence which contains only SDR instructions. In this case, all data bits last one serial root clock cycle on FlexSPI interface. Following diagram indicates the relationship of serial root clock, data and SCLK:

![Figure 27-23. SDR instruction in SDR sequence](image)

- **SDR instruction in DDR sequence**
  DDR sequence is a flash access command sequence that contain DDR instruction which is not DUMMY, it may contain SDR instructions optionally. In the case of SDR instruction in DDR sequence, all data bits last two serial root clock cycles on FlexSPI interface. Following diagram indicates the relationship of serial root clock, data and SCLK:
• DDR instruction in DDR sequence
In the case of DDR instruction in DDR sequence, all data bits last one serial root clock cycle on FlexSPI interface. Following diagram indicates the relationship of serial root clock, data and SCLK:

Figure 27-24. SDR instruction in DDR sequence

Figure 27-25. DDR instruction in DDR sequence

27.5.13.2 Output timing between Chip selection and SCLK
This section describes the output timing relationship of Chip select (on A_SS0_B/A_SS1_B/B_SS0_B/B_SS1_B) and SCLK. The timing relationship is a little different for SDR sequence and DDR sequence.

• Chip Select timing in SDR sequence
For SDR sequence, the delay from chip select assertion and the SCLK rising edge is (FLSHxCR1[TCSS]+0.5) cycles of serial root clock; The delay from SCLK falling edge and chip select deassertion is FLSHxCR1[TCSH] cycles of serial root clock. Following diagram indicates the timing relationship between chip selection and SCLK:
For DDR sequence, the delay from chip selection assertion and SCLK rise edge is (TCSS+0.5) cycles of serial root clock; The delay from SCLK fall edge and chip selection deassertion is (TCSH+0.5) cycles of serial root clock.

**NOTE**
When AHB RX prefetch is enabled, and prefetch can be aborted, set TCSH to be least 1 to guarantee positive chip select hold time after SCK falling edge.

Following diagram indicates the timing relationship between chip selection and SCLK:

For certain device (such as FPGA device), there is limitation on the interval between Chip Selection valid. FlexSPI will ensure a delay time between chip selection valid if register field FLSHxCR1[CSINTERVAL] is set to non-zero value. The delay time is: CSINTERVAL*1024 cycle of serial root clock no matter SDR or DDR sequence. Please set this register field value to zero if there is no this limitation for external device.
Following diagram indicates the timing of chip selection interval.
27.5.14 FlexSPI Input Timing

This section describes the input timing of FlexSPI.

27.5.14.1 RX Clock Source Features

This section describes the features of each RX clock source.

- **Internal dummy read strobe and loopback internally** (MCR0[RXCLKSRC]==0)
  
  Supporting legacy device with zero device output hold time.
  
  Saving one pad (DQS pad).
  
  Supporting low frequency clock for boot up usage.

- **Internal dummy read strobe and loopbacked from DQS pad** (MCR0[RXCLKSRC]==1)
  
  Supporting higher frequency than mode "MCR0[RXCLKSRC]==0".
  
  Supporting device doesn't provide read strobe.

- **Flash provided read strobe** (MCR0[RXCLKSRC]==3)
  
  Supporting the highest frequency.
  
  Supporting device provides read strobe.

27.5.14.2 Input timing for sampling with dummy read strobe

This section describes the input timing when sampling with internal dummy read strobe (MCR0[RXCLKSRC] is set to 0x0 or 0x1). The timing is very similar for sampling with dummy read strobe loopback internally and loopback from pad. But it could achieve...
higher read frequency by sampling with dummy read strobe loopback from DQS pad because it will compensate the delay of SCLK output path and Data pin input path. The input timing is different for SDR mode and DDR mode.

- **Input timing for sampling with dummy read strobe in SDR mode**

For SDR Read/Learn instruction, FlexSPI samples input data pins with the falling edge of dummy read strobe. Following diagram indicates the input timing for sampling with dummy read strobe in SDR mode.

![Input Timing for sampling with dummy read strobe in SDR mode](image)

**Figure 27-29. Input Timing for sampling with dummy read strobe in SDR mode**

- **Input timing for sampling with dummy read strobe in DDR mode**

For DDR Read/Learn instruction, FlexSPI sample input data pins with both rise and fall edge of dummy read strobe. Following diagram indicates the input timing for sampling with dummy read strobe in DDR mode.

![Input Timing for sampling with dummy read strobe in DDR mode](image)

**Figure 27-30. Input Timing for sampling with dummy read strobe in DDR mode**
27.5.14.3 Input timing for sampling with flash provided read strobe

This section describes the input timing when sampling with flash provided read strobe (MCR0[RXCLKSRC] is set to 0x3). The input timing is different for SDR mode and DDR mode.

**NOTE**

There are no known devices that provide read strobe and support SDR mode operation.

There are two kinds of Flash provided read strobe:

- **Flash provide read strobe with SCLK**

  For certain flash devices, it provides both read data and read strobes with SCLK. Then the read strobe edge is aligned with read data change. FlexSPI controller should delay read strobe by half cycle in serial root clock (with DLL) and then sample read data with delayed strobe. Refer [DLL configuration for sampling](#) for more details.

  Following diagrams indicates the input timing for sampling with flash read strobe in SDR mode and DDR mode:

![Diagram](image)

**Figure 27-31. Input Timing 2 for Flash provided read strobe in SDR mode**
Figure 27-32. Input Timing 2 for Flash provided read strobe in DDR mode

27.5.14.4 DLL configuration for sampling

The input timing is different for those four sampling clock source. This is handled by setting register DLLxCR differently according to the sampling clock source mode. DLL is a delay line chain, which could be set to a fixed number of delay cells or auto-adjusted to lock on a certain phase delay to the reference clock.

- In following cases, DLLxCR should be set 0x00000100 (1 fixed delay cells in DLL delay chain):
  - Sampling data with Dummy read strobe loopbacked internally (MCR0[RXCLKSRC]=0x0)
  - Sampling data with Dummy read strobe loopbacked from DQS pad (MCR0[RXCLKSRC]=0x1)
- When data is sampled with Flash provided read strobe (MCR0[RXCLKSRC]=0x3) and flash provides read strobe with SCLK, DLL should be set as following to lock on half cycle of the reference clock (serial root clock)
  - SLVDLYTARGET=0xF
• DLLEN=0x1
• OVRDEN=0x0
• Other fields in DLLxCR should be kept as reset value (all zero)

**NOTE**
If serial root clock is lower than 100 MHz, DLL is unable to lock on half cycle of serial root clock because the delay cell number is limited in delay chain. Then DLL should be configured as following instead:

- OVRDEN=0x1
- OVRDVAL=N: Each delay cell in DLL is about 75 ps~225 ps. The delay of DLL delay chain is (N * Delay_cell_delay), N should be set based on max. DDR frequency that current project supported, N = 21, please notice this is a recommended value. May need to adjust in real application if facing failure.
- Other fields in DLLxCR should be kept as reset value (all zero).

### 27.5.15 XIP Enhanced Mode

FlexSPI always supports Execute-In-Place (XIP), no matter external device provided XIP enhanced mode or not. Execute-In-Place is supported by putting program code on External device, then read/execute on external device directly by AHB read access to SFM space. There is no configuration or status polling needed during AHB read access to External device memory and AHB RX buffer is fully transparent to software.

Certain devices provide XIP enhanced mode to improve code execution. In this mode, there is no need to provide Command code for Read Sequence. It saves many cycles for Command Instructions and greatly improves code execution. This XIP enhanced mode is entered/exit by a special sequence which is device specified. Please refer to external device datasheet for more detail.

Normally, the XIP enhanced mode is entered by following sequence:

1. Enable XIP enhanced mode in External Flash by IP command
2. Send the first Read Sequence to External Flash device with correct Mode bits. Command code is needed in this Read sequence.
3. Send following Read sequences to External Flash device with correct Mode bits. Command code is not needed in these Read Sequences. But Mode bits should be sent according to Flash specified. Otherwise Flash will exit Execute-In-Place Enhanced mode.
The instruction JMP_ON_CS in FlexSPI should be used to support external device XIP enhanced mode. This instruction is only allowed in AHB Read command, otherwise there will be IPCMDERR or AHBCDMERR error interrupt generated if this interrupt is enabled. JMP_ON_CS should never be used if device doesn't support XIP enhanced mode. To support XIP enhanced mode, the first instruction in the Read Sequence should be Command instruction and the last valid instruction should be JMP_ON_CS (with operand 0x1).

For the first AHB read Command triggered, FlexSPI will execute the instructions from the instruction pointer 0 in the sequence (which is Command instruction). After this sequence executed FlexSPI will save operand in JMP_ON_CS instruction as start pointer for next Command to current device internally. For the following AHB read Command triggered, FlexSPI will execute from instruction pointer 0x1 and Command instruction is bypassed.

Following diagram indicates XIP operation with Flash XIP Enhanced mode:

![Figure 27-33. XIP Enhanced Mode operation](image)

### 27.6 Application information

This section describes applications supported by the FlexSPI module.

#### 27.6.1 FlexSPI Initialization

FlexSPI controller initialization sequence is as following:

- Enable controller clocks (AHB clock/IP Bus clock/Serial root clock) in System level.
- Power the FlexSPI SRAM using PDRUNCFG registers.
- Release FlexSPI from reset using PRSTCRL registers.
- Set MCR0[MDIS] to 0x1 (Make sure controller is configured in module stop mode)
- Configure module control registers: MCR0, MCR1, MCR2. (Don't change MCR0[MDIS])
- Configure AHB bus control register (AHBCR) and AHB RX Buffer control register (AHBRXBUFxCR0) optionally, if AHB command will be used
- Configure Flash control registers (FLSHxCR0, FLSHxCR1, FLSHxCR2) according to external device type
• Configure DLL control register (DLLxCR) according to sample clock source selection
• set MCR0[MDIS] to 0x0 (Exit module stop mode)
• Configure LUT as needed (For AHB command or IP command)
• Reset controller optionally (by set MCR0[SWRESET] to 0x1)

External device needs configuration by IP command normally after controller initialization. For example, the device configuration is done by WRITE STATUS command for most serial NOR Flash.

### 27.6.2 Overview of Error Flags

The following table gives an overview of error category, flags and triggered source.

**Table 27-9. Error category and flags in FlexSPI**

### 27.6.5 Application on Serial NAND Flash device

This section provides the example sequences for serial NAND flash device (Micron Flash MT29 series). The operation to serial NAND flash is quite similar to serial NOR flash.

READ operation sequence is as following:
- Page Read (Transfer the data from the NAND Flash array to the cache register)
- Get Feature to read the status
- Random Data Read

The following table shows Page Read command sequence.

#### Table 27-30. Page Read command

<table>
<thead>

#### 27.6.6 Application on FPGA device

FPGA device should be accessed by AHB command. All AHB accesses to FPGA will be transparent to SW driver (no SW intervention). There may be some special requirements from FPGA device.

1. **Device type may be different on A1/A2/B1/B2**
   
   For this case, clear the MCR2[SAMEDEVICEEN] bit and configure FLShxCR0 and FLShxCR1 register separately for up to four external devices.

2. **Device needs different wait cycle for Programming.**
   
   The AHB write wait cycle number could be set separately for these four external devices (by register field FLShxCR2[AWRWAIT]). Software could configure the sequences in LUT with different DUMMY instructions (operand will determine dummy cycle). Note that FlexSPI will hold AHB bus ready for this wait time, so AHB Bus performance may become very low when this wait time is very long.

3. **Device needs different wait cycle for Reading.**
   
   The AHB Read Sequence index and Sequence Number could be set separately for these four external devices (by register field FLShxCR2[ARDSEQID] and FLShxCR2[ARDSEQNUM]). Software could configure the sequences in LUT with different DUMMY instruction (operand will determine dummy cycle).

4. **Device may be sensitive to read instruction clock cycle number**
   
   Device will be sensitive to read instruction clock cycle number if its internal memory is implemented similar as FIFO. For this case, software could send the data size information to external device by DATSZ instruction. FPGA device should decode the data size information and determine how much data bytes should be popped.

5. **Device may needs interval time between Chip selection valid**
This could be handled by register field FLSHxCR1[CSINTERVAL] setting.

6. **Device may use SCLK as reference clock for its internal PLL**

In this case, SCLK should be free-running and clock frequency should be stable. This could be achieved by setting MCR0[SCKFREERUNEN] and use SDR sequence only.

### 27.7 Memory Map and register definition

This section includes the FlexSPI module memory map and detailed descriptions of all registers.

#### 27.7.1 Register Access

All registers can be accessed with 8-bit, 16-bit, and 32-bit width operations. Never change the setting value of reserved fields in control registers. Changing the value of reserved fields may impact the normal functioning of the controller.

**NOTE**

For usage that FlexSPI is capable of accessing sensitive memory contents, protection should be done to FlexSPI controller using resource isolation (e.g. XRDC2, XRDC, RDC) or any kind of equivalent partition control via SCFW, to make sure only trusted software be allowed to access the FlexSPI controller register interface.

#### 27.7.2 FlexSPI register descriptions

##### 27.7.2.1 FlexSPI memory map

FlexSPI base address: 402A_8000h

FlexSPI2 base address: 402A_4000h

</tbody>
</table>
| 6     | READADDROP | AHB Read Address option bit. This option bit is intend to remove AHB burst start address alignment limitation. When FlexSPI controller is used for FPGA application, there may be requirement that FlexSPI fetch exactly the byte number as AHB burst. In this case, FPGA device should be designed as non-wordaddressable and this option bit should be set 0.  
0b - There is AHB read burst start address alignment limitation when flash is accessed in parallel mode or flash is wordaddressable.  
1b - There is no AHB read burst start address alignment limitation. FlexSPI will fetch more data than AHB burst required to meet the alignment requirement. |
| 5     | PREFETCHEN | AHB Read Prefetch Enable. When AHB read prefetch is enabled, FlexSPI will fetch more flash read data than current AHB burst needed so that the read latency for next AHB read access will be reduced. |
| 4     | BUFFERABLEE | Enable AHB bus bufferable write access support. This field affects the last beat of AHB write access, refer for more details about AHB bufferable write.  
0b - Disabled. For all AHB write access (no matter bufferable or non-bufferable ), FlexSPI will return AHB Bus ready after all data is transmitted to External device and AHB command finished.  
1b - Enabled. For AHB bufferable write access, FlexSPI will return AHB Bus ready when the AHB command is granted by arbitrator and will not wait for AHB command finished. |
| 3     | CACHABLEEN | Enable AHB bus cachable read access support.  
0b - Disabled. When there is AHB bus cachable read access, FlexSPI will not check whether it hit AHB TX Buffer.  
1b - Enabled. When there is AHB bus cachable read access, FlexSPI will check whether it hit AHB TX Buffer first. |
| 2-1   | Reserved |
| 0     | APAREN | Parallel mode enabled for AHB triggered Command (both read and write) .  
0b - Flash will be accessed in Individual mode.  
1b - Flash will be accessed in Parallel mode. |

#### 27.7.2.8.2 Function

The LUT Key Register contains the key to lock and unlock LUT. Refer to Look Up Table for details.

27.7.2.9.2 Function

The LUT control register is used along with LUTKEY register to lock or unlock LUT. This register has to be written immediately after writing 0x5AF05AF0 to LUTKEY register for the lock or unlock operation to be successful. Refer Look Up Table for details on locking/unlocking LUT. Setting both the LOCK and UNLOCK bits as "00" or "11" is not allowed.

</tr>
</tbody>
</table>
The max flash size supported for each device is 512 MB. When FLHSZ setting value is greater than 0x400000, the device flash size would be taken as 512 MB. The max total flash size supported (for all 4 devices) is also 512 MB. If the total flash size is larger than 512 MB, only 512 MB address space is accessible.

#### 27.7.2.15.2 Function

The Flash control register 1 contains the setting for FlexSPI to meet Flash device specific timings and Flash internal address space.

#### 27.7.2.15.3 Diagram

The diagram shows the bits and their functions along with the reset values.

---
### 27.7.2.15.4 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-16 CSINTERVAL</td>
<td>This field is used to set the minimum interval between flash device Chip selection deassertion and flash device Chip selection assertion. If external flash has a limitation on the interval between command sequences, this field should be set accordingly. If there is no limitation, set this field with value 0x0. When CSINTERVALUNIT is 0x0, the chip selection invalid interval is: CSINTERVAL * 1 serial clock cycle; When CSINTERVALUNIT is 0x1, the chip selection invalid interval is: CSINTERVAL * 256 serial clock cycle. <strong>NOTE:</strong> The chip selection interval is 2 cycle at least even if CSINTERVAL is less than 2.</td>
</tr>
</tbody>
</table>
| 15 CSINTERVALUNIT | CS interval unit  
0b - The CS interval unit is 1 serial clock cycle  
1b - The CS interval unit is 256 serial clock cycle |
| 14-11 CAS | Column Address Size.  
When external flash has separate address field for row address and column address, this field should be set to flash column address bit width. FlexSPI will automatically split flash mapped address to Row address and Column address according to CAS field and WA field setting. This bit should be set to 0x0 when external Flash don't support column address. FlexSPI will transmit all flash address bits as Row address. For flash address mapping, please refer to Flash memory map for more detail. |
| 10 WA | Word Addressable.  
This bit should be set when external Flash is word addressable. If Flash is word addressable, it should be access in terms of 16 bits. At this time, FlexSPI will not transmit Flash address bit 0 to external Flash. For flash address mapping, please refer to Flash memory map for more detail. |
| 9-5 TCSH | Serial Flash CS Hold time.  
This field is used to meet flash TCSH timing requirement. Serial flash CS Hold time promised by FlexSPI is: TCSH in serial root clock cycles (for both SDR and DDR mode). Please refer to FlexSPI Input Timing for more detail. |
| 4-0 TCSS | Serial Flash CS setup time.  
This field is used to meet flash TCSS timing requirement. Serial flash CS Setup time promised by FlexSPI is: (TCSS + 1/2) serial root clock cycles (for both SDR and DDR mode). Please refer to FlexSPI Input Timing for more detail. |

### 27.7.2.16 Flash Control Register 2 (FLSHA1CR2 - FLSHB2CR2)

#### 27.7.2.16.1 Offset

</tbody>
</table>
27.7.2.16.2 Function
Flash Control Register 2 contains setting field for AHB Bus access configuration. If the 4 external device are in different types, AHB read/write command may use different command sequences and AHB bus ready wait time may be also different.

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>IPCR0</td>
<td>A0h</td>
</tr>
</tbody>
</table>

27.7.2.18.2 Function

The IP control registers provide all the configuration required for IP commands. This register provides the flash device’s start address, instead of SoC address, to be accessed for IP command. FlexSPI will determine the chip select automatically according to this start address.

**NOTE**

- It’s not allowed to issue IP command crossing Flash device boundaries. Otherwise there will be IPCMDERR interrupt generated.
- This register should be set before IP command triggered.
- This register setting should not be changed while an IP command is in progress.

27.7.2.19.2 Function
The IP control registers provide all the configuration required for IP command. This register provides the flash read/program data size, sequence index in LUT, sequence number and individual/parallel mode setting for IP command.

NOTE
- This register should be before IP command triggered.
- This register setting should not be changed before IP command finished.

Field | Function
--- | ---
5-2 RXWMRK | Watermark level is (RXWMRK+1)*64 Bits. Interrupt register bit IPRXWA is set when filling level in IP RX FIFO is no less than Watermark level by FlexSPI. There will be a DMA request when the filling level is no less than Watermark level and DMA read is enabled (register bit RXDMAEN is set). There will be an IPRXWA (IP RX FIFO watermark available) interrupt generated when the filling level is no less than Watermark level and IPRXWA interrupt is enabled (register bit INTEN_IPRXWA is set).

**NOTE:** After write-1-clear to INTR[IPRXWA], read address should be rolled back to start address (memory mapped).

1 RXDMAEN | IP RX FIFO reading by DMA enabled. 0b - IP RX FIFO would be read by processor. 1b - IP RX FIFO would be read by DMA.

0 CLRIPRXF | Clear all valid data entries in IP RX FIFO. The read/write pointers in IP RX FIFO will be reset.

<tr>
<td>11-8</td>
<td>Reserved</td>
</tr>
<tr>
<td>7-4</td>
<td>Reserved</td>
</tr>
<tr>
<td>3-2</td>
<td>ARBCMDSRC</td>
</tr>
</tbody>
</table>

This status field indicates the trigger source of current command sequence granted by arbitrator. This field value is meaningless when ARB_CTL is not busy (STS0[ARBIDLE]=0x1).

- 00b - Triggered by AHB read command (triggered by AHB read).
- 01b - Triggered by AHB write command (triggered by AHB Write).
- 10b - Triggered by IP command (triggered by setting register bit IPCMD.TRG).
- 11b - Triggered by suspended command (resumed).

| 1          | ARBIDLE  |

This status bit indicates the state machine in ARB_CTL is busy and there is command sequence granted by arbitrator and not finished yet on FlexSPI interface. When ARB_CTL state (ARBIDLE=0x1) is idle, there will be no transaction on FlexSPI interface also (SEQIDLE=0x1). So this bit should be polled to wait for FlexSPI controller become idle instead of SEQIDLE.

27.7.2.27  AHB Suspend Status Register (AHBSPNDDS)

27.7.2.27.1  Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>AHBSPNDDS</td>
<td>ECh</td>
</tr>
</tbody>
</table>

27.7.2.27.2  Function
Indicates the status of Suspended AHB Read Prefetch command sequence. When there is IP/AHB command triggered and arbitrator is processing an AHB Read sequence (prefetching more data not for current AHB burst), the prefetch sequence will be suspended and may be resumed when there is no transaction on FlexSPI any more. FlexSPI saves only one AHB prefetch sequence. When a new prefetch sequence is suspended with an active sequence suspended already, previous suspended sequence will be removed and never resumed. Refer Command Abort and Suspend for more details.

<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>LUTa</td>
<td>200h + (a × 4h)</td>
</tr>
</tbody>
</table>
27.7.2.32.2  Function

The LUT is a look-up-table for command sequences. Software should set the sequence index before triggering an IP command or AHB command. FlexSPI will fetch the command sequence from LUT when IP/AHB command triggered. There are 16 command sequences in LUT. Refer Look Up Table for more details.

NOTE
LUT is implemented as memory, so the reset value is unknown.

27.8  AHB Memory Map definition

This section describes FlexSPI module AHB memory map in detail.

27.8.1  AHB Memory Map for Serial Flash memory access

AHB read/write access for serial flash memory is mapped to a specific address range. See the Memory Map and register definition for specific address ranges supported.

AHB Bus feature supported for Serial Flash memory reading:
- Cachable and Non-Cachable access
- Prefetch Enable/Disable
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

AHB Bus feature for Serial Flash memory writing:
- Bufferable and Non-Bufferable access
- Burst size: 8/16/32/64 bits
- All burst type: SINGLE/INCR/WRAP4/INCR4/WRAP8/INCR8/WRAP16/INCR16

Refer Flash access by AHB Command for more details about AHB access to Serial Flash memory.

28.2 Arm Cortex M7 Platform

28.2.1 Overview

The Cortex-M7 platform features a single Arm®Cortex®-M7 processor in this chip. The Arm®Cortex®-M7 processor is a highly efficient, high-performance, embedded processor that features low interrupt latency, low-cost debug, and has backwards compatibility with existing Cortex-M profile processors. The processor has an in-order super-scalar pipeline by which many instructions can be dual-issued, including load/load and load/store instruction pairs because of multiple memory interfaces.

Memory interfaces that the processor supports include:

- Tightly-Coupled Memory (TCM)
- Harvard instruction and data caches and AXI master (AXIM) interface
- Dedicated low-latency AHB-Lite peripheral (AHBP) interface

The Arm Cortex-M7 Platform supports the following:

- 32 KB L1 Instruction Cache
- 32 KB L1 Data Cache
- Floating Point Unit (FPU) with support for the FPv5 architecture
- Internal Trace (TRC)

The number ofIRQs supported for this chip is 160. In addition, it supports various components composing the Arm CoreSight debug/Trace system, such as ETM and CTI.

**NOTE**
This chip supports up to 16 interrupt priority levels, i.e. it implements bits [7:4] of each NVIC Interrupt Priority Register.
28.2.2 Block Diagram

A block diagram for the Cortex-M7 is given below:

29.2 Overview

This section provides an overview of the

- NIC-301 (Network Inter-Connect) AXI arbiter IP

The NIC-301 (by Arm Ltd.) is a configurable AXI arbiter between several masters and slaves. The NIC-301 IP is designed so that many configuration options are selected at the hardware design stage, determined by SoC characteristics and needs, while several other configuration options are software-controlled.

This chapter covers in brief the NIC-301 while providing configuration details on the NIC-301 instances used in the chip. For complete details on the NIC-301 design, see the Arm specification, *AMBA® Network Interconnect (NIC-301) Technical Reference Manual, version r2p3*. 
NOTE
The NIC-301 default settings are configured by NXP's board support package (BSP), and in most cases should not be modified by the customer. The default settings have gone through exhaustive testing during the validation of the part, and have proven to work well for the part's intended target applications. Changes to the default settings may result in a degradation in system performance.

29.2.1 NIC-301 Main Features
Key features of the NIC-301 module include the following:

- Address space memory mapping.
- Programmer's view, for software-configured parameters, via internal "GPV" ports.
- Support for cross-clock domain synchronization.

29.2.2 Modes and Operations
The NIC-301 supports a normal functional mode only.

29.3 External Signals
There are no external I/O interfaces for NIC-301.

29.4 Memory Map and Register Definition
The bus system is composed of five instances: SIM_M7, SIM_PER, SIM_M, SIM_MAIN and SIM_EMS. Three of them have GPV registers which are helpful for bus arbitration and performance. For detailed descriptions of these registers, see the Arm document: DDI0397I_corelink_network_interconnect_nic301_r2p3_trm.pdf.

1. SIM_MAIN registers
The SIM_MAIN GPV base address is GPV0_BASE = 0x41000000. The following registers are implemented in this NIC.
<table>
<thead>
<tr>
<th>Register Name</th>

30.2 Overview

There is 1 OCRAM controller implemented in the chip. One controller is for up to 512 KB on-chip RAM. The size of OCRAM is configured in the FlexRAM module via IOMUXC. For more details, refer to the FlexRAM chapter.

The on-chip RAM block is implemented as an slave module on the 64-bit system AXI bus. Designed as a simple on-chip memory controller, it supports only one AXI port with memory banks. For the AXI port, the read and write transactions are handled by two independent modules. As it is possible to have simultaneous read and write request from the AXI bus, each memory bank has an arbiter with round-robin scheme. After arbitration, the granted read or write access command can then be issued to the memory cell through a read/write MUX.
The memory banks are organized with the lower 2 bits of the address which is the AXI bus address and is 64 bits aligned interleaved. This allows a read access and a write access to be processed at the same time if they are targeted to different memory banks.

Various options are provided for adding a pipeline or wait-states in a read/write access, in order to ensure flexible timing control at both high and low frequencies.

The internal block diagram is shown in the figure below.

![On-chip RAM Block Diagram](image)

**Figure 30-1. On-chip RAM Block Diagram**

### 30.3 Basic Functions
30.3.1 Read/Write Arbitration

The detailed rules used in arbitration are as follows:

- If there is no granted read or write in the last cycle, and there is only a read request or a write request, the request will be granted.
- If there is no granted read or write in the last cycle, and there are both read or write requests coming in at the same time, the read request will be granted first.
- If a granted read/write transaction has just finished, the write/read request will have the higher priority in the next cycle.
- If the first read/write access request in a transaction is granted, all the data transfer in this burst will be finished before the next arbitration begins, that is, the round-robin arbitration mechanism is based on AXI transaction, not data access.

30.4 Advanced Features

This section describes some advanced features designed to avoid timing issues when the on-chip RAM is working at high frequency.

All of the features can be disabled/enabled by programming the corresponding fields of the General Purpose Register (IOMUXC.GPR3) bits [3:0] in the IOMUX chapter.

30.4.1 Read Data Wait State

When the wait state is enabled, it will take 2 cycles for each read access (each beat of a read burst).

This can avoid the potential timing problem caused by the longer memory access time at higher frequency.

When this feature is disabled, it only takes 1 clock cycle to finish a read transaction. That is, read data is available in the next cycle of read request becomes valid on the bus.

For the normal OCRAM, the read data wait state is configurable via IOMUXC.GPR3[0].

30.4.2 Read Address Pipeline

When this feature is enabled, the read address from the AXI master is delayed 1 cycle before it can be accepted by the on-chip RAM.
Advanced Features

This can avoid setup time issues for the read access on the memory cell at high frequency. Enabling this feature can cost, at most, 1 more clock cycle for each AXI read transaction, that is, at most 1 more clock cycle for each read burst with multiple beats of data.

When this feature is disabled, the read address from the AXI master can be accepted by the on-chip RAM without delay, and data can become ready for master at next clock cycle (if no other access and no read data wait).

For the normal OCRAM, the read address pipeline is configurable via IOMUXC.GPR3[1].

30.4.3 Write Data Pipeline

When this feature is enabled, the write data from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would cost at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write data from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write address is also ready at this cycle).

For the normal OCRAM, the write data pipeline is configurable via IOMUXC.GPR3[2].

30.4.4 Write Address Pipeline

When this feature is enabled, the write address from the AXI master would be delayed 1 cycle before it can be accepted by the on-chip RAM.

This can avoid setup time issue for the write access on the memory cell at high frequency. Enabling this feature would take at most 1 more clock cycle for each AXI write transaction, that is, at most 1 more clock cycle for each write burst with multiple beats of data.

When this feature is disabled, the write address from the AXI master can be accepted by the on-chip RAM without delay, and data can be written to memory at this cycle (if no other access and write data is also ready at this cycle).
For the normal OCRAM, the write address pipeline is configurable via IOMUXC.GPR3[3]

### 30.5 Programmable Registers

There are no programmable registers in this block; however, OCRAM configurable bits can be found in the IOMUX Controller (IOMUXC) general purpose registers found here.

- TrustZone bits: IOMUXC_GPR10

For additional information see application note AN12077: Using the i.MX RT FlexRAM. This document describes the flexible memory array available on the i.MX RT MCUs. It includes the following information:

• Configuration of the bank array
• Memory type size definition
• Available memory controllers
• Power domains and clocks
• Interrupt request generation
• Example of FlexRAM configuration usage on a specific application use case
31.2 Overview

31.2.1 Introduction
This SoC has 512 KB of on-chip RAM which is shared by I-TCM, D-TCM and general purpose On Chip RAM (OCRAM). The FlexRAM is the manager of the big on-chip RAM array.

31.2.2 Features
The FLEXRAM includes the following features:

- Integrated I-TCM and D-TCM RAM controller
  - 64-bit I-TCM interface and 2x 32-bit D-TCM interface.
  - The controller supports up to 512 KB TCM (for both ITCM and DTCM) space.
  - The controller supports two access modes:
    - Fast mode: RAM accesses is expected to be finished in 1-cycle for both read and write.
    - Wait mode: RAM accesses is expected to be finished in 2-cycle. Wait mode for read and write path can be enabled separately.
  - Synchronous interface to the M7 Core, run at the same frequency as the core
  - Automatically clock gating control to reduce power consumption
- Integrated OCRAM controller
  - single SRAM bank controller.
  - support up to 512 KB SRAM size
  - Synchronous to the system bus, runs at the same frequency as bus fabric
- Parameterized RAM Array
  - Support up to 512 KB total memory space
  - Support up to 32 block of 32-bit RAM
- RAM Array portioning
  - RAM size of ITCM, DTCM and OCRAM can be configured from 0 to full RAM Array size separately
  - Step of the RAM size partitioning for ITCM, DTCM and OCRAM is (Total RAM SIZE)/16
  - Flexible RAM bank organization.
- Flexible power mode:
  - Run mode: All RAM banks are powered on
• Retention mode: Only 1 (Bank0) out of the 16 RAM banks is on while the rest banks are powered off
• Partial mode: 8 out of the 16 RAM banks (bank8 to bank15) can be powered off dynamically
• Bank8~15 can be disabled with hardware fuse setting. When the fuse is set, total RAM size will be limit to 256 KB
• Generates interrupt upon TCM, OCRAM access out of configured RAM range

31.2.3 Block diagram

![FLEXRAM block diagram](image)

Figure 31-1. FLEXRAM block diagram

31.3 Functional description

FLEXRAM converts AXI and TCM interface signals to RAM interface signals and implements mux control for OCRAM, DTCM and ITCM access to on-chip RAM.
31.3.1 Interface Conversion

FLEXRAM integrate OCRAM controller which converts AXI master interface signals to RAM interface signals (Please see OCRAM section). OCRAM controller can support to add pipeline or wait-state in read/write access by IOMUX GPR.

FLEXRAM also implement TCM controller module to convert DTCM/ITCM interface to RAM interface. TCM read/write access can be extended to 2 cycles by setting TCM_CTRL register. When DTCM and ITCM access unallocated RAM address, TCM controller can send tcm_err to DTCM/ITCM interface.

31.3.2 RAM Bank Allocation

OCRAM, DTCM and ITCM share 512 KB of on-chip RAM. SW can configure from 0 to 512 KB full RAM array size for OCRAM, DTCM and ITCM by IOMUX GPR16 and GPR17. The RAM size step is 32KB. The allocated RAM bank can be not overlapped for OCRAM, DTCM and ITCM. Table below show an example of a 128KB ITCM, 128KB DTCM and 256KB OCRAM configuration.

<table>

</tbody>
</table>

### 31.3.3 Low power modes

FLEXRAM has input fuse control signal to control OCRAM bank8~bank15 interface access. When the fuse bit is programmed, bank8~bank15 can't be accessed again and can be power down.

### 31.3.4 Clocks

The following table describes the clock sources of the FlexRAM module.

<table>
<thead>
<tr>
<th>Clock name</th>

</tr>
</tbody>
</table>

### 31.3.5 Reset

FLAMRAM has 2 reset signals. One is used for OCRAM interface and in always on power domain. The other is used for TCM interface and in core power domain.

### 31.3.6 Interrupts

FLEXRAM can generate interrupt in the following cases:
- OCRAM, DTCM or ITCM access the RAM address which is not allocated.
31.4 Memory Map and register definition

This section includes the FLEXRAM module memory map and detailed descriptions of all registers.

31.4.1 FLEXRAM register descriptions

## 31.4.1.5 Interrupt Enable Register (INT_SIG_EN)

### 31.4.1.5.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>INT_SIG_EN</td>
<td>18h</td>
</tr>
</tbody>
</table>

### 31.4.1.5.2 Function

This register is used to select which interrupt status is indicated to the Host System as the interrupt. These status bits all share the same interrupt line. Setting any of these bits to 1 enables interrupt generation. The corresponding Status register bit will generate an interrupt when the corresponding interrupt signal enable bit is set.

32.2 Overview

This section provides an overview of the AHB to IP Bridge (AIPSTZ). This particular peripheral is designed as the bridge between AHB bus and peripherals with the lower bandwidth IP Slave (IPS) buses.

32.2.1 Features

The following list summarizes the key features of the bridge:

- The bridge supports the IPS slave bus signals. This interface is only meant for slave peripherals.
- The bridge supports 8-, 16-, and 32-bit IPS peripherals. (Accesses larger than the size of a peripheral are not supported, except to 32-bit memory.)
- The bridge supports a pair of IPS accesses for 64-bit and certain misaligned AHB transfers to 32-bit memory in 64-bit platforms.
- The bridge directly supports up to 32 16-Kbyte external IPS peripherals, and 2 global external IPS peripheral spaces. The bridge occupies 1 MBytes of total address space.
The bridge provides configurable per-block and per-master access protections. Access permissions are based on bus master (e.g. DMA or core) privilege levels and resource domain. More details on the protection features and configuration can be found in the Security Reference Manual.

Peripheral read transactions require a minimum of 2 hclk clocks, and unbuffered write transactions require a minimum of 3 hclk clocks.

The bridge uses one single asynchronous reset and one global clock.

### 32.3 Clocks

The following table describes the clock sources for AIPSTZ. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

<table>
<thead>
<tr>
<th>Clock name</th>
<th>Clock Root</th>
<th>Description</th>
</tr>
</thead>
<tbody>

</tr>
</tbody>
</table>

### 32.4 Functional Description

The AIPS bridge serves as a protocol translator between the AHB system bus and the IP bus.

Support is provided for generating a pair of 32-bit IP bus accesses when targeted by a 64-bit system bus access, or a misaligned access which crosses a 32-bit boundary. No other bus-sizing access support is provided.

The AHB to IP bridge is the interface between the AHB and on-chip IPS peripherals, which are sub-blocks containing readable/writable control and status registers.

The AHB master reads and writes these registers through the AIPSTZ. The bridge generates block enables, the block address, transfer attributes, byte enables and write data as inputs to the IPS peripherals. The bridge captures read data from the IPS interface and drives it on the AHB.

Each bridge that connects to the IPS (or peripherals) are referred as AIPS. The chip has several separate AIPS modules, and peripherals are grouped and assigned under each AIPS block. The list of peripherals are indicated as n-1, ... and n-x for AIPS-1, ... and AIPS-x respectively.
AIPS occupies a 1-Mbyte portion of the address space. The register maps of the IPS peripherals are located on 16-Kbyte boundaries. Each IPS peripheral is allocated one 16-Kbyte block of the memory map, and is activated by one of the block enables from the bridge. Up to thirty-two 16-Kbyte external IPS peripherals may be implemented, occupying contiguous blocks of 16-Kbytes. Two global external IPS block enables are available for the remaining address space to allow for customization and expansion of addressed peripheral devices. In addition, a single "non-global" block enable is also asserted whenever any of the thirty-two non-global block enables is asserted.

The bridge is responsible for indicating to IPS peripherals if an access is in supervisor or user mode. It may block user mode accesses to certain IPS peripherals or it may allow the individual IPS peripherals to determine if user mode accesses are allowed. In addition, peripherals may be designated as write-protected.

The bridge supports the notion of "trusted" masters for security purposes. Masters may be individually designated as trusted for reads, trusted for writes, or trusted for both reads and writes, as well as being forced to look as though all accesses from a master are in user-mode privilege level. Refer to AIPSTZ Memory Map/Register Definition for more information.

The AIPSTZ prevents access to a peripheral if the transaction originated from a source from a resource domain that has been explicitly omitted. Resource domains are assigned in the RDC submodule. Please refer to the RDC chapter for programming details.

All peripheral devices are expected to only require aligned accesses equal to or smaller in size than the peripheral size. An exception to this rule is supported for 32-bit peripherals to allow memory to be placed on the IPS.

### 32.5 Access Protections

The AIPSTZ bridge provides programmable access protections for both masters and peripherals. It allows the privilege level of a master to be overridden, forcing it to user-mode privilege, and allows masters to be designated as trusted or untrusted.

Peripherals may require supervisor privilege level for access, may restrict access to a trusted master only, and may be write-protected. IP bus peripherals are subject to access control policies set in both CSU registers and AIPSTZ registers. An access is blocked if it is denied by either policy.

Masters and peripherals are assigned to one or more resource domains in the RDC submodule (see the RDC chapter for details). Depending on RDC programming, masters transactions through the AIPSTZ may or may not be allowed access to peripherals in different resource domains.
32.6 Access Support

Aligned 64-bit accesses, aligned and misaligned word and half word accesses, as well as byte accesses are supported for 32-bit peripherals. Misaligned accesses are supported to allow memory to be placed on the IPS.

Peripheral registers must not be misaligned, although no explicit checking is performed by the AIPS bridge. The bridge will perform two IPS transfers for 64-bit accesses, word accesses with byte offsets of 1, 2, or 3, and for half word accesses with a byte offset of 3. All other accesses will be performed with a single IPS transfer.

Only aligned half word and byte accesses are supported for 16-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

Only byte accesses are supported for 8-bit peripherals. All other accesses types are unsupported, and results of such accesses are undefined. They are not terminated with an error response.

32.7 Initialization Information

The AIPS bridge should be programmed before use.

The following registers should be initialized: The Master Privilege Registers (AIPSTZ_MPRs), the Peripheral Access Control registers (AIPSTZ_PACRs), and the Off-platform Peripheral Access Control registers (AIPSTZ_OPACRs) described in AIPSTZ Memory Map/Register Definition.

32.7.1 Security Block

The AIPSTZ contains a security block that is connected to each off-platform peripheral. This block filters accesses based on write/read, non-secure, and supervisor signals.

Each peripheral can be individually configured to allow or deny each of the following transactions as described in the table below:

<table>
<thead>
<tr>
<th>Config Bit</th>
<th>Write</th>
<th>Non-Secure</th>
<th>Supervisor</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>0</td>
<td>0</td>
<td>Secure User Read</td>
</tr>
</tbody>
</table>

Table continues on the next page...
Table 32-3. Peripheral Access Configuration options (continued)

<table>
<thead>
<tr>
<th>Config Bit</th>
<th>Write</th>
<th>Non-Secure</th>
<th>Supervisor</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>0</td>
<td>0</td>
<td>1</td>

<td>0</td>
<td>Non-Secure User Write</td>
</tr>
<tr>
<td>7</td>
<td>1</td>
<td>1</td>
<td>1</td>
<td>Non-Secure Supervisor Write</td>
</tr>
</tbody>
</table>

Each peripheral has a security configuration (sec_config_X) input for determining whether to allow or deny a given access type. These are 8-bit vectors, with each bit corresponding to one of the transactions above as listed in the Config Bit column of Table 32-3. If the bit is asserted (1'b1), the transaction is allowed. If the bit is negated (1'b0), the transaction is not allowed.

For example, if peripheral 0 is configured as follows:

```
sec_config_0 [7:0] = 8'b0011_0011
```

This peripheral can only be accessed by secure transactions. Bits 0, 1, 4, and 5 are asserted and these bits refer to the four types of secure transactions. If an insecure transaction is attempted to this peripheral, it will result in an error.

Eight bits per peripheral across an entire system can result in a large number of configuration bits that must be assigned and controlled, most likely in a series of registers in another block. To reduce the number of register bits required predefined sets of security profiles can be defined and encapsulated in an external security translation block. The table below describes one set of security profiles that has been proposed for use with the AIPSTZ.

<table>

</tr>
</tbody>
</table>
Information regarding CSU is provided in the Security Reference Manual. Contact your NXP representative for information about obtaining this document.

A 3-bit input, 8-bit output translation block can be used such that only three register bits are required to set the security profile and the translation block will drive the correct 8-bit configuration vector. Each peripheral connected to the AIPSTZ would require this translation block. The top level AIPSTZ has this three bit input line `csu_sec_level[2:0]' corresponding to each peripheral X.

### 32.8 AIPSTZ Memory Map/Register Definition

The memory map for the AIPS SW-visible registers is shown in the table below. The MPROT and OPACR fields are 4 bits in width. Some bits may be reserved depending on device.

#### 32.8.1 Master Privileged Registers (AIPSTZx_MPR)

Each AIPSTZ_MPR specifies 16 4-bit fields defining the access privilege level associated with a bus master in the platform, as well as specifying whether write accesses from this master are bufferable shown in Table 32-5

The registers provide one field per bus master, where field 15 corresponds to master 15, field 14 to master 14,... field 0 to master 0 (typically the processor core). The master index allocation is shown in the table below.

**Table 32-5. MPROT Field**

32.8.2 Off-Platform Peripheral Access Control Registers (AIPSTZx_OPACR)

Each of the off-platform peripherals have an Off-platform Peripheral Access Control Register (AIPSTZ_OPACR) which defines the access levels supported by the given block.

Each AIPSTZ_OPACR has the following format shown in Table 32-7

<table>
<thead>
<tr>
<th>Bit</th>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 3   | BW    | **Buffer Writes** - This bit determines whether write accesses to this peripheral are allowed to be buffered.  
1. Buffered writes are not available for AIPSTZ. This bit should be set to '0'. |
| 2   | SP    | **Supervisor Protect** - This bit determines whether the peripheral requires supervisor privilege level for access. |
| 1   | WP    | **Write Protect** - This bit determines whether the peripheral allows write accesses. |
| 0   | TP    | **Trusted Protect** - This bit determines whether the peripheral allows accesses from an untrusted master. |

Chapter 33
Display and Camera Overview

33.1 Display and Camera Overview

The following modules are a part of the Display and Camera system:

- LCD Interface (LCDIF): 24-bit parallel RGB LCD interface
- PXP pixel pipeline: 2D graphics and pixel/image processing engine
- Camera Sensor Interface (CSI): up to 24-bit parallel interface for image sensor

The following figure shows the high-level integration scheme of the chip display and camera system.

![Block Diagram](image-url)
33.1.1 PiXel Processing Pipeline

The pixel processing pipeline is used to perform image processing on image/video buffers before sending to an LCD display.

The main features of PXP include:

- Multiple input/output format support, including YUV/RGB/Grayscale
- Supports both RGB/YUV scaling
- Supports overlay with Alpha blending
- Supports Rotation of 0, 90, 180, and 270 degrees in conjunction with vertical and horizontal flip options

33.1.2 LCD Interface

The LCDIF is a general purpose display controller that is used to drive a wide range of display devices. These displays can vary in size and capability. Many of these displays have had an asynchronous parallel MPU interface for command and data transfer to an integrated frame buffer. There are other popular displays that support moving pictures and require the RGB interface mode (called DOTCLK interface in this document) or the VSYNC mode for high-speed data transfers.

The block has several major features:

- Bus master interface to source frame buffer data for display refresh and a DMA interface to manage input data transfers from the LCD requiring minimal CPU overhead.
- 8/16/18/24 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for MPU, VSYNC and DOTCLK LCD interfaces to support a wide variety of displays.

33.1.3 CMOS Sensor Interface

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and
output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.
- 8-bit data port for YCC, YUV, or RGB data input.
- 8-bit/10-bit/16-bit data port for Bayer data input.
- Full control of 8-bit/pixel, 10-bit/pixel or 16-bit/pixel data format to 64-bit receive FIFO packing.
- Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
- Support for double buffering two frames in the external memory.
- Single interrupt source to interrupt controller from maskable interrupt sources:
  - Start of Frame
  - End of Frame
  - Change of Field
  - FIFO full
  - FIFO overrun
  - DMA transfer done
  - CCIR error
  - AHB bus response error
- Configurable master clock frequency output to sensor.
- Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).

34.2 Overview

This chapter presents the CMOS Sensor Interface (CSI) architecture, operation principles, and programming model.

The CSI enables the chip to connect directly to external CMOS image sensors. CMOS image sensors are separated into two classes, dumb and smart. Dumb sensors are those that support only traditional sensor timing (Vertical SYNC and Horizontal SYNC) and output only Bayer and statistics data, while smart sensors support CCIR656 video decoder formats and perform additional processing of the image (for example, image compression, image pre-filtering, and various data output formats).

The capabilities of the CSI include:

- Configurable interface logic to support most commonly available CMOS sensors.
- Support for CCIR656 video interface as well as traditional sensor interface.
• 8-bit / 10-bit / 16-bit data port for Bayer data input.
• Full control of 8-bit/pixel, 10-bit/pixel or 16-bit / pixel data format to 64-bit receive FIFO packing.
• Receive FIFO overrun protection mechanism.
• Embedded DMA controllers to transfer data from receive FIFO or statistic FIFO through AHB bus.
• Support 2D DMA transfer from the receive FIFO to the frame buffers in the external memory.
• Support double bufferring two frames in the external memory.
• Single interrupt source to interrupt controller from maskable interrupt sources: Start of Frame, End of Frame, Change of Field, FIFO full, FIFO overrun, DMA transfer done, CCIR error and AHB bus response error.
• Configurable master clock frequency output to sensor.
• Statistic data generation for Auto Exposure (AE) and Auto White Balance (AWB) control of the camera (only for Bayer data and 8-bit/pixel format).

### 34.3 External Signals

The table below describes the external signals for the CSI. The external signals are tied between the CSI module and an external CMOS sensor.

### 34.5 Principles of Operation

The information found here describes the modes of operation of the sensor interface.

The CSI is designed to support generic sensor interface timing as well as CCIR656 video interface timing. Traditional CMOS sensors typically use VSYNC (SOF), HSYNC (BLANK), and PIXCLK signals to output Bayer or YUV data. Smart CMOS sensors, that
come with on-chip imaging processing, usually support video mode transfer. They use an embedded timing codec to replace the VSYNC and HSYNC signal. The timing codec is defined by the CCIR656 standard.

The CSI can support connection with the sensor as follows.

- To connect with one 8-bit sensor, the sensor data interface should connect to CSI_DATA[9:2].
- To connect with one 10-bit sensor, the sensor data interface should connect to CSI_DATA[9:0].
- To connect with one 16-bit sensor, the sensor data interface should connect to CSI_DATA[15:0].

#### 34.5.1 Data Transfer with the Embedded DMA Controllers

The CSI has two embedded DMA controllers, one for the receive FIFO and the other for the statistic FIFO. It supports 2D DMA transfer from the receive FIFO to the frame buffers in the external memory and linear DMA transfer from the statistic FIFO.

To transfer data from the RxFIFO to the external memory, the user should set the start address in the frame buffer where the transferred data is stored, the parameters of the frame buffers, and the parameters of the image coming from the sensor. The user can have two frame buffers in the external memory. Each one will store a frame of image coming from the sensor. The embedded DMA controller will first write the frame buffer1 and then frame buffer2. These two frame buffers will be written by turns. The start address should be aligned in double words and set in the CSIDMASA-FB1 and CSIDMASA-FB2 registers. In the CSIFBUF_PARA register, the user should set the stride of the frame buffer to show how many double words to skip before starting to write the next row of the image. In the CSIIMAG_PARA register, the user should set the width and height of the image coming from the sensor. The RxFF_LEVEL and DMA_REQ_EN_RFF bits in CSICR3 registers also need to be set before the data transfer starts. When the number of the data in the RxFIFO reaches the trigger level, a DMA request will be sent to the embedded DMA controller and the data will be read out.
from the RxFIFO and written through AHB bus into the external frame buffers. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA_BURST_TYPE_RFF bits in CSICR2 register. After all data in an image frame are transferred, the DMA_TSF_DONE_FB1 or DMA_TSF_DONE_FB2 bit will be set in CSISR register and the interrupt can be triggered if the corresponding enable bit is set in CSICR1 register. The DMA_REFLASH_RFF bit in CSICR3 can be used to activate or restart the embedded DMA controller.

The RxFIFO has the overrun protection mechanism in case the RxFIFO is overrun during data transfer. If the RxFIFO is full and more data needs to be received during the data transfer, the RxFIFO will be overwritten continuously and all 128 words of data in the RxFIFO before overrun occurred will be discarded; the corresponding 128 words memory space in the frame buffer will keep the previous values.

To transfer data from the statistic FIFO to the external memory, the user should set the start address of the external memory where the transferred data is stored and the total transfer sizes. The start address and the transfer sizes are all aligned in double words and should be set in the CSIDMASA-STATFIFO and CSIDMATS-STATFIFO registers. The STATFF_LEVEL and DMA_REQ_EN_SFF bits in CSICR3 registers should also be set before the data transfer starts. When the number of the data in the STATFIFO reaches the trigger level, a dma request will be sent to the embedded DMA controller and the data will be read out from the STATFIFO and written through AHB bus into the external memory. The burst type of transfer can be INCR4, INCR8 and INCR16 by setting DMA_BURST_TYPE_SFF bits in CSICR2 register. After all expected data (defined by the total transfer sizes) are transferred, the DMA_TSF_DONE_SFF bit will be set in CSISR register and an interrupt can be triggered if the SFF_DMA_DONE_INTEN is enabled in CSICR1 register. The DMA_REFLASH_SFF bit in CSICR3 can be used to activate or re-start the embedded DMA controller.

### 34.5.2 Gated Clock Mode

VSYNC, HSYNC, and PIXCLK signals are used in gated clock mode.

A frame starts with an active edge on VSYNC, then HSYNC asserts and holds for the entire line. The Pixel clock is valid as long as HSYNC is asserted. Data is latched at the active edge of the valid pixel clocks. HSYNC deasserts at the end of line. Pixel clocks then become invalid and CSI stops receiving data from the stream. For the next line the HSYNC timing repeats. For the next frame the VSYNC timing repeats.
34.5.3 Non-Gated Clock Mode

In non-gated clock mode, only the VSYNC and PIXCLK signals are used; the HSYNC signal is ignored.

![Timing Diagram](image)

**Figure 34-1. Non-Gated Clock Mode Timing Diagram**

The overall timing of non-gated mode is the same as the gated-clock mode, except for the HSYNC signal. HSYNC signal is ignored by the CSI. All incoming pixel clocks are valid and cause data to be latched into RxFIFO. The PIXCLK signal is inactive (states low) until valid data is ready to be transmitted over the bus.

Figure 34-1 shows the timing of a typical sensor. Other sensors may have the slightly different timing from that shown. The CSI can be programmed to support rising/falling-edge triggered VSYNC, active-high/low HSYNC, and rising/falling-edge triggered PIXCLK.

34.5.4 CCIR656 Interlace Mode

In CCIR656 interlace mode, only the PIXCLK and CSI_DATA[9:2] signals are used. The start of frame and blank signals are replaced by a timing codec which is embedded in the data stream. Each active line starts with an Start of Active Video (SAV) code and ends with an End of Active Video (EAV) code. In some cases, digital blanking is inserted in between EAV and SAV code. The CSI decodes and filters out the timing-coding from the data stream, recovering VSYNC and HSYNC signals for internal use, such as statistical block control. Data is forwarded to the data receive and packing block in a sequential manner without reordering—that is, field 1 followed by field 2. The fields must be reordered in software to get back the original image.

Change of Field (COF) interrupt is triggered upon every field change. The interrupt service routine reads the status register to check for the current field.
According to the CCIR656 specification, the image must be in 625/50 PAL or 525/60 NTSC format. In addition, the image is interlaced into odd and even fields with vertical and horizontal blank data being filled into certain lines. Data must be in YCbCr422 format, each pixel contains 2 bytes, either Y + Cr or Y + Cb. These requirements are set for TV systems. The CSI module supports PAL and NTSC format only.

The following figure describes the frame structure in PAL system, showing vertical and horizontal blanking.

![Figure 34-2. CCIR656 Interlace Mode (PAL)](image)

The following figure describes the general timing for a single line, showing SAV and EAV.

![Figure 34-3. CCIR656 General Line Timing](image)

The coding tables recommended by the CCIR656 specification are shown below. It is used in the CCIR656 mode to decode the video stream. An interrupt is generated for SOF, which is decoded from the embedded timing codec.

### 34.5.5 CCIR656 Progressive Mode

For a CMOS camera system of VGA or CIF resolution, strict adherence to the interlace requirements stated in the CIR standard is not required.

The image is considered to have only 1 active field which is scanned in a progressive manner. This active field is regarded as field 1 and the F-bit in the timing codec is ignored by the decoder. Most sensors support CCIR timing in this mode (progressive) by default.

The following figure shows the typical flow of progressive mode.
An interrupt is generated for SOF but not for COF. In the general case, when SOF information is retrieved from the embedded coding, it is known as internal VSYNC mode. In other cases, when the VSYNC signal is provided by the sensor, it is known as external VSYNC mode. The CSI can be operated in internal or external VSYNC mode.

### 34.5.6 Error Correction for CCIR656 Coding

According to the algorithm for CCIR coding, protection bits in the SAV and EAV are encoded in the way that allows a 1-bit error to be corrected, or a 2-bit error to be detected by the decoder. This feature is supported by the interlace mode CCIR decoder in CSI.

For the 1-bit error case, users can select the error to be corrected automatically, or simply shown as a status flag instead. For the 2-bit error case, because the decoder is unable to make a correction, the error would be shown as a status flag only.

An interrupt can be generated upon the detection of an error. This signal can be enabled or disabled without affecting the operation of the status bit.

### 34.6 Interrupt Generation

The information found here describes CSI events that generate interrupts.
34.6.1 Start Of Frame Interrupt (SOF_INT)

The source of an SOF interrupt is dependent on the mode of operation.

In traditional mode, VSYNC signal is taken from sensor and SOF_INT is generated at the rising or falling edge (programmable) of VSYNC.

In CCIR interlace mode, the SOF interrupt information is retrieved from the embedded coding and SOF_INT is generated.

In CCIR progressive mode, there are two sources of an SOF interrupt:

- In **internal** VSYNC mode, SOF is retrieved from the embedded coding.
- In **external** VSYNC mode, VSYNC is taken from the sensor and SOF is generated at the rising edge of VSYNC.

34.6.2 End Of Frame Interrupt (EOF_INT)

An EOF interrupt is generated when the frame ends and the complete frame data in RXFIFO is read.

The EOF event triggering works with the RX count register (CSIRXCNT). Software sets the RX count register to the frame size (in words). The CSI RX logic then counts the number of pixel data being received and compares it with the RX count. If the preset value is reached, an EOF interrupt is generated and the data in the RXFIFO are read. If a SOF event is detected before this happens, the EOF interrupt is not generated.

34.6.3 Change Of Field Interrupt (COF_INT)

The Change of Field interrupt is only valid in CCIR Interlace mode. The COF interrupt is generated when the field toggles, either from field 1 to field 2, or field 2 to field 1.

Software should first check COF_INT bit in the CSI Status Register (CSISTAT) before checking that F1_INT or F2_INT is turned on.

In PAL systems, the field changes at the beginning of the frame and coincides with SOF. For the first field, a COF interrupt is not generated, only an SOF. The COF interrupt is generated for the second field.
34.6.4 CCIR Error Interrupt (ECC_INT)

The CCIR Error Interrupt is only valid for CCIR Interlace mode. An ECC interrupt is generated when an error is found on the SAV or EAV codes in the incoming stream. When this happens, the ECC_INT status bit is set.

34.6.5 RxFIFO Full Interrupt (RxFF_INT)

A RxFIFO full interrupt is generated when the number of data in RXFIFO reaches the water mark defined by RxFF_LEVEL in CSICR3.

34.6.6 Statistic FIFO Full Interrupt (STATFF_INT)

A StatFIFO full interrupt is generated when the number of data in STATFIFO reaches the water mark defined by STATFF_LEVEL in CSICR3.

34.6.7 RxFIFO Overrun Interrupt (RFF_OR_INT)

A RxFIFO Overrun interrupt is generated when the RxFIFO has 128 words data and more data is being written in.

34.6.8 Statistic FIFO Overrun Interrupt (SFF_OR_INT)

A StatFIFO Overrun interrupt is generated when the STATFIFO has 64 words data and more data is being written in.

34.6.9 Frame Buffer1 DMA Transfer Done Interrupt (DMA_TSF_DONE_FB1)

A DMA transfer done interrupt of frame buffer1 is generated when one frame of data are transferred from RxFIFO to the frame buffer1 in the external memory.
34.6.10 Frame Buffer2 DMA Transfer Done Interrupt
(DMA_TSF_DONE_FB2)

A DMA transfer done interrupt of frame buffer2 is generated when one frame of data are
transferred from RxFIFO to the frame buffer2 in the external memory.

34.6.11 Statistic FIFO DMA Transfer Done Interrupt
(DMA_TSF_DONE_SFF)

A StatFIFO DMA transfer done interrupt is generated when all the data are transferred
from StatFIFO to the external memory. The transfer size is defined in the STATFIFO
DMA Transfer Size Register.

34.6.12 AHB Bus Response Error Interrupt (HRESP_ERR_INT)

An AHB Bus response error interrupt is generated when a bus error is detected.

34.7 Data Packing Style

Careful attention to endianess is needed given the different port sizes at different stages
of the image capture path.

To enable flexible packing of image data before storage in the FIFOs, the CSI module
can swap data fields by use of the PACK_DIR and the SWAP16_EN bit in CSI Control
Register 1 (CSICR1).

The CSI module accepts 8-bit, 10-bit or 16-bit data from the sensor by configuring
PIXEL_BIT bit in CSI Control Register 1 (CSICR1) and TWO_8BIT_SENSOR bit in
CSI Control Register3 (CSICR3). The input data is packed according to the setting of
PACK_DIR bit. The packed data is stored in the RX FIFO according to the setting of the
SWAP16_EN bit.

For 10-bit per pixel data format, each pixel is expanded to 16 bits by appending 6 zeros
bits to the most significant bit.
34.7.1 RX FIFO Path

34.7.1.1 Bayer Data

Bayer data is a type of raw data from the image sensor. This byte-wide data must be converted to the RGB space or YUV space by software. The data path for Bayer data is from the CSI to memory. If the system is in little endian, then the PACK_DIR bit should be set to 0. 8-bit data format from a sensor is packed to 64 bits as P7.P6.P5.P4.P3.P2.P1.P0, where P0 is the pixel coming in time slot 0 (first data) and P3 is the pixel coming in time slot 3 (the last data in the 64-bit word). When the data is addressed as bytes by software, P0 is transferred first, P1 is transferred next, and so on. 10-bit data format is packed to 64 bits as 000000.P3.000000.P2.000000.P1.000000.P0, where P0 is the 10-bit data coming in time slot 0 (first pixel) and P3 is the 10-bit data coming in time slot 3 (fourth pixel). 16-bit data is packed to 64 bits as P7.P6.P5.P4.P3.P2.P1.P0.

34.7.1.2 RGB565 Data

RGB565 data is processed data from the image sensor, which can be put directly into the display buffer. The data is 16 bits wide. The data path is from CSI to memory to the display controller. On the sensor side, data must be transmitted as P0 first, followed by P1, and so on. For each pixel, whether the MSB or LSB is sent first depends on the endianness of the sensor. Data is 16 bits wide with the MSB labeled RG, and the LSB labeled GB. P0 is represented as RG0 and GB0.

CSI receives data in one of the following sequence:

- RG0, GB0, RG1, GB1, while RG0 comes out at time slot 0 (first data), and GB1 comes out at time slot 3 (last data)
- GB0, RG0, GB1, RG1

Using the first sequence as an example, and assuming the system is running in little endian, the data is presented as:

- 8-bit data from sensor: RG0, GB0, RG1, GB1, …
- 64-bit data before storage in the CSI RX FIFO (PACK_DIR bit = 1):
  RG0GB0RG1GB1RG2GB2RG3GB3
- 64-bit data in CSI RX FIFO (SWAP16_EN bit enabled):
  RG3GB3RG2GB2RG1GB1RG0GB0
34.7.1.3 RGB888 Data

This is another kind of processed data from image sensor, which can be used for further image processing directly. Each of the data consist of 8-bit Red, 8-bit Green, and 8-bit Blue data. An example of timing scheme is shown in the following figure.

An optional scheme to pack a dummy byte is provided. For every group of 3 bytes data, a dummy zero is packed to form a 32-bit word as shown in the following figure. The dummy zero can be packed at the LSB position or MSB position. Using RGB888A_FORMAT_SEL in CSI_CSICR18[18] to determine to put the dummy bytes packed at LSB or MSB position.
Figure 34-6. Optional Dummy Byte Packing Scheme

Format 1 with Pack direction = '1' (MSB first)
34.7.2 STAT FIFO Path

Statistics only works for Bayer data in 8-bit per pixel format. It generates 16-bit statistical output from the 8-bit Bayer input (CSI_DATA[13:6]). The outputs are Sum of Green (G), Sum of Red (R), Sum of Blue (B), and Auto Focus (F). Each output is 16-bits wide.

The settings of PACK_DIR and SWAP16_EN bits in the CSICR1 register have no effect on the input path. The PACK_DIR only controls how the 16-bit stat output is packed into the 32-bit STAT FIFO.

When the PACK_DIR bit = 1, the stat data is packed as:

First 32-bit: RG
Second 32-bit: BF
...

When the PACK_DIR bit = 0, the stat data is packed as:

First 32-bit GR
Second 32-bit: FB
...

34.8 CSI Memory Map/Register Definition

34.8.1 CSI Control Register 1 (CSI_CSICR1)

This register controls the sensor interface timing and interrupt generation. The interrupt enable bits in this register control the interrupt signals and the status bits. That means status bits will only function when the corresponding interrupt bits are enabled.

Address: 402B_C000h base + 0h offset = 402B_C000h

34.8.2 CSI Control Register 2 (CSI_CSICR2)

This register provides the statistic block with data about which live view resolution is being used, and the starting sensor pixel of the Bayer pattern. It also contains the horizontal and vertical count used to determine the number of pixels to skip between the 64 x 64 blocks of statistics when generating statistics on live view image that are greater than 512 x 384.

34.8.6 CSI RX Count Register (CSI_CSIRXCNT)

This register works for EOF interrupt generation. It should be set to the number of words to receive that would generate an EOF interrupt.

There is an internal counter that counts the number of words read from the RX FIFO. Whenever the RX FIFO is being read, by either the CPU or the embedded DMA controller, the counter value is updated and compared with this register. If the values match, then an EOF interrupt is triggered.

Address: 402B_C000h base + 14h offset = 402B_C014h

35.2 Overview

The enhanced Liquid Crystal Display Interface (LCDIF) is a general purpose display controller

The LCDIF block supports the following:

- Displays that support moving pictures and require the RGB interface mode (DOTCLK interface).

The LCDIF provides fully programmable functionality to supported interfaces:

- Bus master interface to source frame buffer data for display refresh. This interface can also be used to drive data for "Smart" displays.
- DMA interface to manage data transfers between "Smart" displays and SoC.
- 8/16/18/24 bit LCD data bus support available depending on I/O mux options.
- Programmable timing and parameters for DOTCLK LCD interfaces.
35.3 External Signals

35.5 Functional Description

Bus Interface Mechanisms through Initializing the LCDIF, describe the internal pipeline for the LCDIF interfaces. Differences for each mode are then described in separate sections, as follows:

- DOTCLK Interface

LCDIF pin usage by interface mode is described in LCDIF Pin Usage by Interface Mode.
 Functional Description

35.5.1 Bus Interface Mechanisms

The LCDIF module has memory-mapped control, data and status registers. It provides several interfaces to transfer data between the display and SoC.
The bus master interface is used to initiate the requests to transfer data from external memory to the display. It is completely autonomous, or no CPU intervention is required, to manage the cyclical nature of refreshing standard display types.

The DMA interface requires the SoC integrated APBDMA engine to manage data transfers on behalf of the LCDIF. APBDMA descriptor chains are created to manage control and data flow between the LCDIF and external display. This interface is typically used for "Smart" display types that integrate their own frame buffer and control interface. The APBDMA engine is used to reduce the CPU compute requirements to complete the display solution.

The host CPU executes display drivers to manage the display solution. The following sections describe the system bus interface mechanisms.

### 35.5.1.1 Bus Master Operation in Write/Display Modes

The LCDIF block has a bus master interface that initiates requests for data to drive the display. The LCDIF_MASTER bit must be set to 1 to enable the bus master interface. Software should program all control registers required to transfer the frame sequence.

The DOTCLK mode is used to refresh the display at the desired refresh rate and resolution, and drive displays that don't integrate a display buffer memory. When the display is refreshed, the LCDIF will automatically update the LCDIF_CUR_BUF_ADDR register with the value in LCDIF_NEXT_BUF_ADDR at the end of current frame and start fetching the next frame from the new address. If the LCDIF_NEXT_BUF_ADDR register was not updated within a frame refresh cycle, LCDIF will keep transmitting the last frame until a new value is programmed into that register.

### 35.5.1.2 System Bus Master Performance

The performance of the LCDIF block can be controlled by changing the burst length and the outstanding cycle issuing capability depending on the memory bandwidth requirements. Two fields in the LCDIF_CTRL2 register will throttle system memory requests. The LCDIF_CTRL2_OUTSTANDING_REQS field will control how many requests the LCDIF can have in flight on any given clock cycle. This should be programmed based on the expected system bus latency for returned read data. Also, the LCDIF_CTRL2_BURST_LEN_8 bit will set the number of 64 bit words requested for each LCDIF system bus request to either 8 or 16 QWORDS. Generally, 4 outstanding requests of length 16 will provide enough performance to drive any standard display.
resolution. These configuration bits are intended to change the access pattern of the LCDIF to optimize system bus throughput when other system masters will contend for system memory resources.

### 35.5.1.3 DMA Operation in MPU Read Mode

Data can be transferred between an external display and the SoC using the APBDMA interface. This mode is enabled by setting the LCDIF_MASTER bit to 0 and is typically used with "Smart" displays. The APBDMA module executes DMA descriptor chains to process the desired data flow sequence. The data can be either frame buffer data or display control data.

### 35.5.2 Write Data Path

LCDIF supports raster based frame buffers and there is no support for tiled buffers.

There are several options to accommodate endianness of display buffers in memory before the data is processed for the external display. The LCDIF_CTRL[INPUT_DATA_SWIZZLE] field provides the following options for data word multiplexing:

- **00 (0): No swizzle (little-endian)**
- **01 (1): Swap bytes 0 and 3, swap bytes 1 and 2 (big-endian)**
- **10 (2): Swap half-words**
- **11 (3): Swap bytes within each half-word**

The LCDIF_CTRL[WORD_LENGTH] field indicates the input data/pixel format. LCDIF_TRANSFER_COUNT register denotes how much data is contained in each frame. The LCDIF_TRANSFER_COUNT[H_COUNT] field indicates the number of pixels per line and LCDIF_TRANSFER_COUNT[V_COUNT] indicates the total number of lines per frame. The LCDIF_CTRL1[BYTE_PACKING_FORMAT] field can be used to specify which bytes within the 32-bit word are going to be valid. For example, if the entire 32-bit word is valid, LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be set to 0xF, if only lower 3 bytes of each word in the frame buffer are valid, then LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be set to 0x7.

The LCDIF_CTRL[LCD_DATABUS_WIDTH] field suggests the width of the bus going to the display controller. There is an option to source all 32 bits of the input word and transfer it to the output I/O display interface. If the LCDIF_CTRL[LCD_DATABUS_WIDTH] is not the same as LCDIF_CTRL[WORD_LENGTH], LCDIF will perform RGB to RGB color space conversion. For example, if the input frame has fewer bits per pixel than the display, as in a 16 bpp input frame going to 24 bpp LCD, LCDIF will pad the MSBs of each color to...
the LSBs of the same color for each pixel. If the input frame has more bits per pixel than the display, for example, 24 bpp input frame going to 16 bpp LCD, LCDIF will drop the LSBs of each color channel to convert to the lower color depth. LCDIF also has the capability to support delta pixel displays by swizzling the R, G and B colors of each pixel in the odd and even lines of the frame separately by programming the LCDIF_CTRL2[ODD_LINE_PATTERN] and the LCDIF_CTRL2[EVEN_LINE_PATTERN] bit fields. This operation occurs after the RGB-to-RGB color space conversion operation.

The following list shows how the different input/output combinations can be obtained:

- **LCDIF_CTRL[WORD_LENGTH]=1** indicates that the input is 8-bit data. Any combination of LCDIF_CTRL1[BYTE_PACKING_FORMAT] is permissible. Limitation: LCDIF_TRANSFER_COUNT[H_COUNT] must be a multiple of the sum of BYTE_PACKING_FORMAT [3], BYTE_PACKING_FORMAT [2], BYTE_PACKING_FORMAT [1] and BYTE_PACKING_FORMAT [0]. LCDIF_CTRL[LCD_DATABUS_WIDTH] must be 1, indicating an 8-bit data bus.

- **LCDIF_CTRL[WORD_LENGTH]=0** implies the input frame buffer is RGB 16 bits per pixel. LCDIF_CTRL[DATA_FORMAT_16_BIT] field determines the pixels are RGB 555 or RGB 565. Limitation: LCDIF_CTRL1[BYTE_PACKING_FORMAT] should be 0x3 or 0xC if there is only one pixel per word. If there are two pixels per word, it should be 0xF and LCDIF_TRANSFER_COUNT[H_COUNT] will be restricted to be a multiple of 2 pixels.

- **LCDIF_CTRL[WORD_LENGTH]=2** indicates that input frame buffer is RGB 18 bits per pixel, that is, RGB 666. The valid RGB values can be left-aligned or right-aligned within a 32-bit word. The alignment of the valid 18 bits within a word is indicated by the LCDIF_CTRL[DATA_FORMAT_18_BIT] bit. Limitation: LCDIF_CTRL1[BYTE_PACKING_FORMAT] can be 0x7, 0xE or 0xF. Packed pixels are not supported in this case. LCDIF_TRANSFER_COUNT[H_COUNT] can be any number.

- **LCDIF_CTRL[WORD_LENGTH]=3** indicates that the input frame-buffer is RGB 24 bits per pixel (RGB 888). If LCDIF_CTRL1[BYTE_PACKING_FORMAT] is 0x7, it indicates that there is only one pixel per 32-bit word and there is no restriction on LCDIF_TRANSFER_COUNT[H_COUNT]. This is also the option that provides 32 bit output depending on the I/O muxing options available. The fourth byte, or bits [31:24], and connected to the I/Os if this muxing is available in the chip package.
Limitation: If LCDIF_CTRL1[BYTE_PACKING_FORMAT] is 0xF, it indicates that the pixels are packed, that is, there are 4 pixels in 3 words or 12 bytes and LCDIF_TRANSFER_COUNT[H_COUNT] must be a multiple of 4 pixels.

After the RGB to RGB color space conversions, there is one more opportunity to swizzle the data before sending it out to the display or the encoder. This can be done with the LCDIF_CTRL[CSC_DATA_SWIZZLE] field, and it provides the same options as the LCDIF_CTRL[INPUT_DATA_SWIZZLE] register.

Finally, there is an option to shift the output data before sending it out to the display. This is done based on the LCDIF_CTRL[SHIFT_DIR] and LCDIF_CTRL[SHIFT_NUM_BITS] fields.

**Figure 35-2. General Operations in Write Data Path**

The examples in the following figures illustrate some different combinations of register programming for write mode. Assume that the data transferred over the system bus within a 32 bit word is organized as {A7-A0, B7-B0, C7-C0, D7-D0} in 8-bit mode and {A15-A0, B15-B0} in 16-bit mode.

In this example, all 32 bits of the input word are transferred out over an 8 bit display bus. Each byte within the 32 bit word is shifted to the right with zeros appended to bits D[7:6]. The input data bits [7:2] are shifted to the right by 2 bits and presented on the D[5:0].
Figure 35-3. Register programming for write mode

In this 8 bit display interface example, one byte of the input word is deleted and not transferred over the external 8 bit display interface. This mode could be used to transfer 24bpp pixels over the 8 bit interface. In this case, the 4th unused byte is not transferred.
Figure 35-4. Register programming for write mode

The following example uses a 16 bit display interface. Each 16 bit half word is shifted to the right by two bits with zeros appended to the most significant two bits.
Figure 35-5. Register programming for write mode

This example indicates how an unpacked frame buffer can sourced for display. Only a single 16 bit half word within the 32 bit word is transferred out via the 16 display bus.
32 Bit Word

35.5.3 LCDIF Interrupts

LCDIF supports a number of interrupts to aid controlling and status reporting of the block.

All the interrupts have individual mask bits for enabling or disabling each of them. They all get funneled through a single interrupt line connected to the interrupt collector (ICOLL).

The following list describes the different interrupts supported by LCDIF:

- Underflow interrupt is asserted when the clock domain crossing FIFO (TXFIFO) becomes empty but the block is in active display portion during that time. Software should take corrective action to make sure that this does not happen.
- In the bus master mode, the overflow interrupt will be asserted if the block has requested more data than it's FIFOs could hold.
- Cur_frame_done interrupt occurs at the end of every frame.
35.5.4 Initializing the LCDIF

This section describes write modes.

35.5.4.1 Write Modes

The following initialization steps are common to all LCDIF write modes of operation before entering any particular mode.

Initialization steps:

1. Configure the external I/Os to correctly interface the external display, when required.
2. Start the DISPLAY CLOCK (pix_clk) clock and set the appropriate frequency by programming the registers in CCM.
3. Start the BUS CLOCK (apb_clk) and set the appropriate frequency by programming the registers in CCM.
4. Bring the LCDIF out of soft reset and disable the clock gate bit.
5. Set the transfer mode of operation to bus master. The LCDIF_CTRL[MASTER] bit determines the transfer mode selected. Bus master (LCDIF_CTRL[MASTER] =1), APBDMA is the transfer mode to select.
6. Set the LCDIF_CTRL[INPUT_DATA_SWIZZLE] according to the endianness of the LCD controller. Also, set the LCDIF_CTRL[DATA_SHIFT_DIR] and LCDIF_CTRL[SHIFT_NUM_BITS] if it is required to shift the data left or right before it is output.
7. Set the LCDIF_CTRL[WORD_LENGTH] field appropriately: 0 = 16-bit input, 1 = 8-bit input, 2 = 18-bit input, 3 = 24/32-bit input. Also, select the correct 16/18/24 bit data format with the corresponding fields in LCDIF_CTRL register.
8. Set the LCDIF_CTRL1[BYTE_PACKING_FORMAT] field according to the input frame.
10. Enable the necessary IRQs.

35.5.5 DOTCLK Interface

The DOTCLK interface is another mode used in moving picture displays.

It includes the VSYNC, HSYNC, DOTCLK and (optional) ENABLE signals. The interface is popularly called the RGB interface if the ENABLE signal is present.
The DOTCLK mode writes data at high speed to the LCD, and the display operation is synchronized with the VSYNC, HSYNC, ENABLE and DOTCLK signals. The polarities, periods and pulse-widths of the sync signals are programmable using the LCDIF_VDCTRL0-4 registers. The units for the VSYNC signal must be number of horizontal lines and can be selected using the VSYNC_PULSE_WIDTH_UNIT and VSYNC_PERIOD_UNIT bit fields. The VERTICAL_WAIT_CNT is by default given the same unit as the VSYNC_PERIOD. The DISPLAY CLOCK (pix_clk) frequency is managed by the CCM.
In DOTCLK mode, LCDIF_CTRL_BYPASS_COUNT bit must be set to 1. To end the current transfer, the software should make the DOTCLK_MODE bit 0, so that all data that is currently in the LCDIF LFIFO and TXFIFO is transmitted. Once that transfer is complete, the block will automatically clear the RUN bit and issue the cur_frame_done interrupt.

### 35.5.5.1 Code Example

The following code shows an example for programming a 320x240 display.

```
NOTE
Setting up the display must be done via SPI.

// Note: Common initialization steps in Initializing the LCDIF must also be
// executed along with the following code
BF_CS1 (LCDIF_CTRL, DOTCLK_MODE, 1);
BF_CS1 (LCDIF_CTRL, BYPASS_COUNT, 1); //Always for DOTCLK mode
BF_CS1 (LCDIF_VDCTRL0, VSYNC_OEB, 0); //Vsync is always an output in the DOTCLK mode
BF_CS1 (LCDIF_VDCTRL0, VSYNC_POL, 0, HSYNC_POL, 0, DOTCLK_POL, 0, ENABLE_POL, 0);
BF_CS1 (LCDIF_VDCTRL0, ENABLE_PRESENT, 1);
BF_CS2 (LCDIF_VDCTRL0, VSYNC_PERIOD_UNIT, 1, VSYNC_PULSE_WIDTH_UNIT, 1);
BF_CS1 (LCDIF_VDCTRL1, VSYNC_PERIOD, 280);
BF_CS2 (LCDIF_VDCTRL2, HSYNC_PULSE_WIDTH, 10, HSYNC_PERIOD, 360); //Assuming
// LCD_DATABUS_WIDTH is 24bit
BF_CS2 (LCDIF_VDCTRL3, VSYNC_ONLY, 0);
BF_CS2 (LCDIF_VDCTRL3, HORIZONTAL_WAIT_CNT, 20, VERTICAL_WAIT_CNT, 20);
BF_CS1 (LCDIF_VDCTRL4, DOTCLK_H_VALID_DATA_CNT, 320); //Note that DOTCLK_V_VALID_DATA_CNT is
//implicitly assumed to be HW_LCDIF_TRANSFER_COUNT_V_COUNT
BF_CS1 (LCDIF_VDCTRL4, SYNC_SIGNALS_ON, 1);
BF_CS1 (LCDIF_CTRL, RUN, 1);
```

To stop the transfer completely, the ideal way is to make DOTCLK_MODE = 0. In that case, the block will transmit the contents in the FIFO and reset the RUN bit.

### 35.5.6 LUT

The Lookup Table (LUT) is used to expand the 8 bits pixel to 24 bits pixel before output to external displayer. This module is used when input data from memory is 8-bits in width under limited bandwidth system and external displayer has a 24 bits requirement.

There are two 256x24 bits LUT memory in LCDIF module in case of changing LUT during active display. When using LUT function, it should be initialized through single PIO register writing first. Writing data to register LCDIF_LUT0_DATA will trigger storing data to lut0 memory and increase the lut0 memory address LCDIF_LUT0_ADDR automatically. Writing data again to register LCDIF_LUT0_DATA will store the data to memory and increase the memory address accordingly. The same operation is performed while writing to LCDIF_LUT1_DATA and LCDIF_LUT1_ADDR.
After initialization, LCDIF_CUR_BUF_ADDR bit 0 determines which LUT is used during active display.

Lastly, when there is active display, it will use the lowest 8 bits LCDIF data as LUT address and output the 24 bits from the lookup table.

### 35.5.7 Panel Interface Generator (Pigeon Mode)

There are several panel interface signal outputs (CLK signal not included), each of them with dedicated timing purpose as default. This is called "Legacy Mode". Pigeon Mode is a timing mode which can be independently enabled on any of the timing signals, with a unified flexible configuration. Signals within pigeon mode can be programmed into any supported signals, and are interchangeable. The following are the legacy timing signals which support pigeon mode:

- PIGEON[00] – LCD_DATA16
- PIGEON[01] – LCD_DATA17
- PIGEON[02] – LCD_DATA18
- PIGEON[03] – LCD_DATA19
- PIGEON[04] – LCD_DATA20
- PIGEON[05] – LCD_DATA21
- PIGEON[06] – LCD_DATA22
- PIGEON[07] – LCD_DATA23
- PIGEON[08] – LCD_ENABLE
- PIGEON[09] – LCD_HSYNC
- PIGEON[10] – LCD_VSYNC

Each pigeon signal has one local counter with a configurable start point and incremental condition. It will be compared to configuration register value for signal assertion/de-assertion control, plus delta offset for data alignment and other options like polarity/logic operation. A detailed running scenario is as follows:

1. Start local counter on the MASK rising edge (reference point/start point)
2. Increment on event selected through INC_SEL
3. Count and match SET_CNT: assert signal, reset counter (SET_CNT==0 means assert immediately on MASK's rising edge)
4. Count and match CLR_CNT: de-assert signal, stop counter (CLR_CNT==0 means de-assert on MASK's falling edge)

**NOTE**

When local counter is running, further changes to MASK are not cared unless CLR_CNT==0
MASK is the start point for local counter created using a combination any of the options (ANDed) from below:

1. **STATE_MASK** = (FS\|FB\|FD\|FE) \& (LS\|LB\|LD\|LE)
   
   In this case you have 8 bits to select in which vertical/horizontal state your counter starts ticking. This is the most common use-case because timing signals generally relate to scan states.

   For example, for a line timing signal start on Line Begin phase during Frame Begin/Frame Data lines, use the configuration below:

   ![Table 35-4. State Mask Combinations](image)

<table>
<thead>
<tr>
<th>STATE_MASK</th>
<th>LS</th>
<th>LB=1</th>
<th>LD</th>
<th>LE</th>
</tr>
</thead>
<tbody>
<tr>
<td>FS</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>FB=1</td>
<td></td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FD=1</td>
<td></td>
<td>X</td>
<td></td>
<td></td>
</tr>
<tr>
<td>FE</td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

2. **MASK_CNT/MASK_CNT_SEL** (global counter)

   Sometimes a more accurate reference point is required, such as "line 20 in a frame", or "line 12 in Frame Begin state" or "pixel 23 in LD phase". For such use-cases, several Global Counters shared by all pigeons are provided. Global counter type (line counter/frame counter/state counter, etc.) is selected using MASK_CNT_SEL, when global counter matches the MASK_CNT value. The pigeon local counter will start ticking.

3. Use another pigeon signal as mask (SIG_LOGIC=MASK)

   For some tightly coupled signals it is possible to use one as a reference to generate another.

   INC_SEL- select local counter tick event
   a. pclk - pixel clk
   b. line - line start pulse
   c. frame - frame start pulse
   d. another - another pigeon signal

   OFFSET- offset on pclk basis: Some signals need to come out slightly earlier or later than programmed. For example, the CE type signal usually aligns with the Line Data phase, but some panels need it as one cycle pulse before Line Data. The user can set OFFSET to a negative value to achieve this.

Global counters (selectable through MASK_CNT_SEL):
• HCNT / VCNT : normal pclk counter / line counter
• HSTATE_CNT / VSTATE_CNT: similar to above, but reset when state changes
• HSTATE_CYCLE / VSTATE_CYCLE: (see figure below for definition of CYCLE/PERIOD/CNT)

Some panels have multiple Gate Drivers/Source Drivers, so Frame Data / Line Data state may be further split to match each driver, and signals such as CE[n] are only valid during part n of Line Data. For such signals, use LCDIF_PIGEON_CTRL[*_PERIOD] to specify PERIOD where CNT is reset and CYCLE is included. Then the user can select CYCLE as MASK_CNT to generate mask for CE[n].

• FRAME_CNT / FRAME_CYCLE (only for frame-crossing signals): frame cycle counter doesn't have a reset condition; use LCDIF_PIGEON_CTRL1[FRAME_CNT_CYCLES] to reset it.

![Figure 35-8. Definition of CNT, CYCLE, PERIOD](image)

The following are register settings for the figure above:
• LCDIF_PIGEON_CTRL0[LD_PERIOD]=2
• MASK_CNT_SEL = 1 // HSTATE_CYCLE
• MASK_CNT = 1 // CE[1]
• MASK_CNT = 2 // CE[2]
35.5.8 LCDIF Pin Usage by Interface Mode

The following tables detail how the LCDIF level interface pins are used based on the desired mode of operation. The chip level I/Os should also be configured to be consistent with the desired LCDIF operating mode.

**NOTE**

There is an option to internally mux the HSYNC, DOTCLK and ENABLE signals in the DOTCLK mode by setting the MUX_SYNC_SIGNALS bit in the VDCTRL0 register.

### 35.6 Behavior During Reset

BUS CLOCK (apb_clk) and DISPLAY CLOCK (pix_clk) must be running before making any changes to SFTRST or CLKGATE bits.

A soft reset (SFTRST) can take multiple clock periods to complete, so do not set CLKGATE when setting SFTRST.

The reset process gates the clocks automatically.

### 35.7 LCDIF Memory Map/Register Definition

Some of the LCDIF registers (XXX_SET, XXX_CLR, and XXX_TOG) allow direct bit field masking and access.

- When writing 1 to XXX_SET bit fields, these registers allow setting the masked 1 bit fields, while keeping unchanged all bit fields which remain on 0 logic state.
• When writing 1 to XXX_CLR bit fields, these registers allow clearing the masked 1 bit fields, while keeping unchanged all other bit fields which remained on 0 logic state.

• When writing 1 to XXX_TOG bit fields, these registers allow inverting the logic state of all masked 1 bit fields, while they keep unchanged the remaining bit fields which were kept on 0 logic state.

35.7.1 LCDIF General Control Register (LCDIF_CTRLn)

The LCD Interface Control Register provides overall control of the LCDIF block. The LCDIF Control Register provides a variety of control functions to the programmer. These functions allow the interface to be very flexible to work with a variety of LCD controllers, and to minimize overhead and increase performance of LCD programming. The register has been organized such that switching between the different LCD modes can be done with minimum PIO writes.

35.7.4 LCDIF Horizontal and Vertical Valid Data Count Register (LCDIF_TRANSFER_COUNT)

This register tells the LCDIF how much data will be sent for this frame, or transaction. The total number of words is a product of the V_COUNT and H_COUNT fields. The word size is specified by the WORD_LENGTH field.

This register gives the dimensions of the input frame. For normal operation, but V_COUNT and H_COUNT should be non-zero.

</tr>
</tbody>
</table>

35.7.5 LCD Interface Current Buffer Address Register (LCDIF_CUR_BUF)

This register indicates the address of the current frame being transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the current frame of data being sent out via the LCDIF. When the current frame is done, the LCDIF block will assert the cur_frame_done interrupt for software to take action. The block will also copy the LCDIF_NEXT_BUF_ADDR into this bitfield so that the software can program the next frame address into the LCDIF_NEXT_BUF_ADDR bitfield. This address must always be double-word aligned.
Address: 402B_8000h base + 40h offset = 402B_8040h

</tr>
</tbody>
</table>

#### 35.7.6 LCD Interface Next Buffer Address Register (LCDIF_NEXT_BUF)

This register indicates the address of next frame that will be transmitted by LCDIF.

When the LCDIF is behaving as a master, this address points to the address of the next frame of data that will be sent out via the LCDIF. It is up to the software to make sure that this register is programmed before the end of the current frame, otherwise it might result in old data going out the LCDIF. This address must always be double-word aligned.

Address: 402B_8000h base + 50h offset = 402B_8050h

### LCDIF_NEXT_BUF field descriptions

<table>

#### 35.7.7 LCDIF VSYNC Mode and Dotclk Mode Control Register0 (LCDIF_VDCTRL0n)

This register is used to control the VSYNC and DOTCLK modes of the LCDIF so as to work with different types of LCDs like moving picture displays and delta pixel displays.

This register gives general programmability to the VSYNC signal including polarity, direction, pulse width, etc.
Address: 402B_8000h base + 70h offset + (4d × i), where i=0d to 3d

36.2 Overview

This document describes the micro-architecture for the Pixel Processing Pipeline used to process graphics buffers or composite video and graphics data before sending to an LCD display or TV encoder.

It is used to minimize the memory footprint required for the display pipeline and provide an area and performance optimized to both SDRAM-less and SRAM-based systems.

The PXP integrates of several independent processing stages into a cohesive strategy to create flexible pixel pipeline.

The PXP combines the following into a single processing engine:

- Scaling
- Color Space Conversion (CSC)
- Rotation
By integrating multiple blocks, intermediate buffer operations to external memory are removed, reducing external memory bandwidth, power, and software control complexity. The PXP block diagram is shown below.

Figure 36-1. PXP Architecture

### 36.3 Clocks

The following table describes the clock sources for PXP. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

### 36.4 Top-level architecture

The PXP consist of several pipelined blocks that perform the video source frame scaling, color space conversion, alpha-blending/color key algorithm, secondary CSC, pixel correction.
The entire pipeline operate within the requirements of the PXP architecture, and perform operations on either 8x8 or 16x16 pixel blocks in the representative source buffers. The entire pipeline operate within the context of two iteration counters that iterate through the appropriate grid of input blocks to produce the rotated output grid blocks in scan-line order.

Figure 36-1 shows the high-level architecture of the scaling, color space conversion, blending, pixel correction, rotation engines. The Alpha Surface Engine fetches one RGB graphics plane alpha surface (AS). The scaling engine fetches a single processed surface (PS), which can be blended with the AS surface. Although the PXP processes NxN pixel macro blocks, each of the AS or PS surfaces can have any pixel alignment within the output buffer. There are no restrictions and any pixel coordinates within the output buffer are valid. The upper left origin of the output buffer is defined as pixel 0,0. The upper left and lower right coordinates for each of the AS and PS are inclusive within the output buffer.

Figure 36-2 represents a sample output buffer configuration with both an AS and PS included. The alignment of each AS and PS within the output buffer can be at any arbitrary pixel locations. For example, the PS has an upper left coordinate (ULC) of 2,2 and a lower right coordinate (LRC) at pixel 13,13. The maximum value for the ULC and LRC for each of the AS and PS is bounded by the LRC of the output buffer, 15,15 for this example.
The AS engine supports RGB pixel formats, and the PS engine supports RGB, YUV, and YCbCr pixel formats. The CSC1 can be used to convert to RGB pixel formats so that the PS surface can be blended with the AS surfaces in the compositing engine in the RGB color space. There is a single rotation engine in the PXP with a programmable location with two possible rotations, one after PS processing, other just before the transfer to display buffer. Rotation can occur after image composition or at the output of the PS engine. In the first scenario, all the data produced by the AS and PS engines is rotated. When the rotation module is programmed to rotate only PS images, the AS is not rotated, and AS pixels are combined with rotated PS surfaces.

### 36.4.1 Processing Details

The PXP architecture has been driven primarily by the requirement that the output buffer must be processed and rotated without intermediate frame buffer stored in external memory.
This reduces the use of external memory bandwidth requirements thus reducing overall system power consumed.

Since the output of the rotation block must be NxN pixel blocks in scan order, the entire pipeline will operate on NxN pixel blocks. In essence, the pipeline will be able to operate on blocks in a random access fashion, but the entire pipeline will operate within the context of two iteration counters that will iterate through the horizontal and vertical input blocks to generate the required output block.

**Processing Pipeline**

The control block will coordinate the processing of the pixel blocks within the source and destination image buffers. It begins by issuing a command to each stage of the pipeline requesting that operations be done for the block at offset x, y. When the block accepts the command, it asserts its acknowledge signal for a single cycle to indicate the acceptance and allow the control unit to move to the next block.

When the PS and AS fetch engines have received a command, they will fetch the required data and place it into their fetch buffers. If compositing the RGB AS surface with the PS surface, then the output of the PS engine needs to be converted to the RGB color space using CSC1, since all compositing occurs in the RGB color space. For YUV output pixel formats, the CSC1 unit can be enabled to convert pixels into the RGB space for subsequent compositing with AS pixels. If the final output color space is YUV and there is no compositing required (AS not present, for example), then the CSC unit can be bypassed and the pixel data path will pass the YUV pixels to the rotation engine. For YUV output formats, scaling operations, and rotation operations are still valid, but blending RGB AS surfaces with YUV PS surfaces is NOT supported.

The alpha blender/color key module will process a pixel any time that both inputs present valid data.

A handshake will be created between each stage and a pipeline controller to handle the advance of the pipeline and generation of the iteration counters. The pipeline controller will also maintain the interlocks with the LCD interface for the case where the LCD display and pixel processing pipeline use the SRAM to maintain the double buffer block intermediate buffer.

### 36.4.2 Scaling Operation

The scaling engine operates on YUV (or YCbCr) 422 or 420 and any RGB formatted pixels. Each color plane is sourced from color planes indicated by different base address registers.
The scaling source data can be stored as 3 individual planes for each Y, U, and V data, stored as two planes as a single Y and interleaved UV plane, or stored as a single plane with YUV/RGB interleaved on a per byte basis.

The scaled output image is presented to the CSC module as YUV444 or RGB888 pixels with a single byte for each color channel. The scaler can reduce an input image by a maximum factor of 16. In this case, the output image will be 1/16 the dimension of the input image in each of the X and Y axis. There are no limits, essentially, on increasing the source image size. The theoretical maximum increase is 4096 since a 12 bit fractional step function is used when scaling an input image. Scaling in either axis, X or Y is independent, so a source image can appear stretched in either direction.

All source images pass through the scale engine. The PXP alpha blend module and AS pixel streams are in the RGB888 format, so PS pixel buffers must be converted to the RGB888 format for alpha blending. The scaling engine works with the CSC1 module to translate YUV/YCbCr pixel formats to RGB888 for output frame buffer compositing using the alpha blender. The CSC1 unit can be bypassed so compositing can occur in the alpha engine.

The scaling operation is divided into two scaling steps. The first step is a decimation scaler, and the second step is a bilinear filter. The decimation filter provide a maximum down scaling factor of 8, and the subsequent bilinear filter provides a maximum scaling factor of 2. Combined, the maximum scaling factor can be up to 16. The decimation and bilinear scaling engines are independently programmable. There is also an initial offset that is programmable to allow more source data to be considered in the bilinear scaling engine.

### 36.4.3 Decimation Image Scaling

The first of two scaling engines is the decimation filter.

The intent of the decimation filter is to use as much source data as is possible to create the output image frame buffer. The decimation filter simply discards certain pixels from the source PS image depending on the reduction selected.

For RGB pixel formats, each color channel is treated equally since there is the same amount of pixel data within each color plane. For YUV422/420 formats, the chroma samples are already subsampled by 2. In these decimation scenarios, the chroma decimation factor is adjusted to account for the pre-decimation of the chroma samples. For example, since YUV422 is already sub-sampled by 2 horizontally, an X decimation factor of 2 does not apply to the YUV422 pixels in the X direction. All the chroma samples are passed on to the bilinear filter in this case. As another example, an X
decimation factor of 4 will decimate the chroma samples by 2, since this factor combined with the pre-decimation factor of 2 in the pixel source buffers totals an overall decimation factor of 4.

The following example will show which pixels (in green) in a source RGB buffer that are passed to the bilinear filter for an X decimation factor of 2 and a Y decimation factor of 4. All pixels coincident with dashed lines are discarded.

Figure 36-3. RGB decimation X/2, Y/4
Using the same decimation factor as the above scenario for RGB pixels, but using YUV420 source buffers, it can be shown that the decimation factor for the Y and UV components of data are decimated differently. This is due to the pre-decimation of the chroma samples in the source frame buffers. Figure 4: YUV420 decimation X /2, Y /4 indicates that the U/V samples in the X direction are not decimated, but the Y samples in the X direction are decimated by the factor of 2.

Figure 36-4. YUV420 decimation X /2, Y /4
36.4.4 Bilinear Image Scaling Filter

The PXP implements a bilinear scaling filter to resize an input image to a different resolution for display output.

The bilinear filter is a weighted average of the four nearest pixels that can be sourced to approximate the pixel in the output frame buffer.

When scaling YUV data, the UV values are offset by 0x80 (top bit inverted) to shift the signed UV bits into an unsigned equivalent with a range of 0 to 255. YCbCr data does not have to be shifted since it is defined as an unsigned byte. The REG_CSC1_COEF0[YCBCR_MODE] bit controls whether this operation is applied to the input UV bytes.

After scaling, the offset is removed so that the range for UV data is signed from -128 to 127.

The reason for this adjustment is based on the implementation of an unsigned scaling engine, and therefore, is to ensure that the scaled values are handled properly. Consider the following table:

<table>
<thead>
<tr>
<th>Format</th>
<th>pixel0</th>
<th>pixel1</th>
<th>average</th>
<th>Result</th>
</tr>
</thead>
<tbody>
<tr>
<td>decimal</td>
<td>-2</td>
<td>+2</td>

</tr>
</tbody>
</table>

To compute the output pixel value at position as indicated by P, consider the diagram below.
A step function is used to indicate the position of the pixel "P" in the output frame. This position may not coincide with a single pixel position in the input frame buffer. In this case, the four closest pixels in the input frame are used to approximate the value of the pixel in the output frame.

The PXP scaler first computes a linear filter in the X axis to create the two intermediate pixel values Px0 and Px1. The step function's X fractional component is used to provide the weighting factor for blending p00 with p10 to provide Px0. Likewise, Px1 is also derived from a linear filter using p01 and p11.

The equations for Px0 and Px1 are as follows:

\[
Px0 = p00(1-Rx) + p10Rx
\]
\[
Px1 = p01(1-Rx) + p11Rx
\]

The PXP scaler uses the intermediate X pixels Px0 and Px1 and implements a bilinear filter on these two pixel values to produce the final pixel value at position P. The remainder of the step function for the Y axis is used to compute the weighted average pixel result. The equation for final filtered pixel is:

\[
P = Px0(1-Ry) + Px1Ry
\]
36.4.5 YUV 4:2:2 Image Scaling

The following figure illustrates the positioning of YUV samples for the 4:2:2 formats. There are twice as many Y luma samples then U and V chroma samples horizontally.

Consider the scaled output pixel Ps (pixel scaled) which has an accumulated step function of X=1.5 and Y=0.5. The remainder for the step function is Rx = 0.5 and Ry = 0.5. Or, the sub pixel position of output pixel Ps is half way between line 0 and 1 and half way between column 1 and 2.

The Y output component of Ps is simply the bilinear function of the four nearest Y samples from the input image. Specifically, the Y values at [1,0], [2,0], [1,1], and [2,1] are used to compute the Y for Ps.

For the U and V components of Ps, there are no samples present in the column position 1. The bilinear filter uses chroma components located at [0,0], [2,0], [0,1] and [2,1]. Since the chroma components are not sub sampled vertically, the remainder used to combine pixels vertically is Ry=0.5 (the same as for Y). However, horizontally, the scaling engine shifts the remainder by a factor of 2. So an X axis step function value of X=1.5 has a remainder Rx=0.75. Source chroma values are not replicated, they are completely interpolated using the four nearest chroma samples to approximate U and V at Ps.
The following figure illustrates the positioning of YUV samples for the 4:2:0 formats. Chroma is sub sampled both horizontally and vertically. In this format, the chroma frame buffers contain ¼ the data that the luma frame buffers store.

![Diagram of YUV Sample Positioning, 4:2:0](image)

**Figure 36-7. YUV Sample Positioning, 4:2:0**

The Y output component for all scaled pixels in 4:2:0 formats are the same as for the 4:2:2 pixel formats.

The U and V output components have two considerations when computing the output pixel Ps.

1. All chroma samples from the input source image are shifted left and up by ½ a sample position of the input pixel matrix.
2. Odd scan lines are replicated using the previous even chroma scan line values. So, output image chroma values that map between even to odd scan lines are replicated in the vertical axis. In contrast, output image chroma values between odd to even scan lines are interpolated vertically.

The chroma values are interpolated horizontally as in the 4:2:2 pixel format.

As an example, consider the interpolated pixel Ps in the 4:2:0 diagram above. For the Y component, the interpolated output luma is a function of the Y values in the source frame buffer at position [1,0], [2,0], [1,1], [2,1].
For the U and V interpolated samples, the chroma values on scan line position 0.5 are shifted so that they coincide with the even luma sample points. They are also replicated so that a single chroma scan line is used twice. The chroma scan line at 0.5 is replicated to represent the 4:2:2 sample points for scan line 0 and 1. The chroma scan line at 2.5 is replicated to represent the 4:2:2 sample points for scan line 2 and 3. This pattern of chroma replication occurs for the entire source frame buffer during the scaling operation.
