The preceding diagram has two examples for the computation of the scaled chroma output pixel. For chroma at output position PsA (vertical position 0.5), interpolation occurs in the X axis using chroma values at column 0 and column 2. However, since line 0 and line 1 have equal chroma values due to chroma line replication, scaling in the Y axis results in replication of chroma values.

For chroma at output position PsB (vertical position 1.5), interpolation occurs in both the X and Y axis. The Y axis is an interpolation since the chroma values copied to scan line 1 and 2 and not the same.

In summary, any output image pixels that map to an odd scan line above and an even scan line below are interpolated vertically. Output image pixels that map to an even scan line above and an odd scan line below are replicated vertically.

### 36.4.7 RGB/YUV444 Image Scaling

For all RGB formats, the RGB pixels are converted up to RGB888 with 8 bits per each color component.
Then each color component is passed to the scaling engine and each component is treated in the same manor. The RGB scaling operation is the same as for the Y scaling operation described in the preceding sections. Also, YUV444 contains a byte for each color plane at each pixel location, so all three color components are scaled in the same manor.

### 36.4.8 Color Space Conversion (CSC)

The CSC unit converts pixels between color spaces. The CSC1 unit is right after the scaling unit and is dedicated to converting from YUV to RGB. All coefficients are programmed as two's compliment numbers and CSC unit can be bypassed if conversion is not desired in the pixel data path.

### 36.4.9 CSC1 Operation

The CSC1 module receives scaled YUV/YCbCr444 pixels from the scale engine and converts the pixels to the RGB888 color space only if CSC1 is enabled.

The CSC1 module will convert only to the RGB color space and it can be bypassed to allow YUV pixels through the data path. These pixels are loaded into the pixel FIFO for processing by subsequent modules in the pixel data path.

The following equations are used to perform YUV/YCbCr -> RGB conversion. The constants will be stored in the PXP control registers as two's compliment values to allow flexibility in the implementation and to allow for differences in the video encode and decode operations. In addition, this provides a software mechanism to manipulate brightness or contrast.

\[
R = C0(Y+Yoffset) + C1(V+UVoffset)
\]

\[
G = C0(Y+Yoffset) + C3(U+UVoffset) + C2(V+UVoffset)
\]

\[
B = C0(Y+Yoffset) + C4(U+UVoffset)
\]

Note: In the equations above, U and V are synonymous with Cb and Cr in regards to the color space format of the source frame buffer.

Saturation of each color channel is checked and corrected for excursions outside the nominal YUV/YCbCr color spaces. Overflow for the three channels are saturated at 0x255 and underflow is saturated at 0x00.

The table below indicates the expected coefficients for YUV and YCbCr modes of operation:
### 36.4.10 YUV versus YCbCr Support

By default, the PXP color space coefficients are set to support the conversion of YUV data to RGB data.

If YCbCr input is present, software must change the coefficient registers appropriately (see the register definitions for values). Software must also set the YCBCR_MODE bit in the COEFF0 register to ensure proper conversion of YUV versus YCBCR data.

### 36.4.11 Alpha Blending/Color Key

Regardless of pixel input format, the PS and AS pixels are normalized to 32-bits, organized as one alpha and three data bytes. Alpha blending occurs in the RGB space, if blending is required, PS pixels should be converted to RGB space. If no alpha blending is required, then YUV pixels can bypass the alpha blending ALU without color space conversion. All pixels are processed by the pixel ALU, but the ALU operations can be disabled to achieve pixel pass through for either PS or AS source pixels.

### 36.4.12 Alpha Blend

The alpha value for an individual pixel represents a mathematical weighting factor applied to the AS pixel. An alpha value of 0x00 corresponds to a transparent pixel and a value of 0xFF corresponds to an opaque pixel.

The effective alpha value for an AS pixel is determined by the AS_CTRL[ALPHA] and AS_CTRL[ALPHA_CTRL] register fields. If AS_CTRL[ALPHA_CTRL] = ALPHA_OVERRIDE, the alpha value for the pixel is taken from the AS_CTRL[ALPHA]. This can be useful for applying a constant alpha to an entire image or for image formats that don't include an alpha value. If AS_CTRL[ALPHA_CTRL] =

</table>
ALPHA_MULTIPLY, the pixel's alpha value will be multiplied by the pixel's ALPHA value in order to allow scaling of the pixel's alpha or to provide better control for pixel formats such as RGB1555, which only contains a single bit of alpha.

For each color channel, the equation used to blend two source pixels is defined below:

\[ \text{Gá} = \text{PIO programmed global alpha (8-bit value)}. \]
\[ \text{Eá} = \text{Embedded alpha associated with AS pixel}. \]
\[ \text{á} = \text{Gá} \times \text{Eá} + 0x80 \]

The result for the red channel as an example:

\[ R[7:0] = (\text{á} \times \text{PS.r}) + ((1 - \text{á}) \times \text{AS.r}) \]

When \( \text{á} \) is 0xff, the PS pixel will not be blended with the AS pixel, but PS will be passed as the output pixel and will not be blended with AS. In this case, AS will be discarded. Likewise, if \( \text{á} \) is 0x00 for a given pixel, PS will be loaded as the output pixel.

AS_CTRL[ALPHA_INVERT] provides the option to invert the final alpha value. This essentially inverts the effect the alpha value has on the AS and PS blending operation.

### 36.4.12.1 Porter-Duff Alpha Blend

Porter-Duff blend includes 12 blending modes to describe digital image composite. These processes include Clear, Source Only, Destination Only, Source Over, Source In, Source Out, Source Atop, Destination Over, Destination In, Destination Out, Destination Atop and XOR. Through these processes it can achieve any 2D image composite.

To control the blending modes, please see the following picture. All the registers showed below are included in HW_PXP_ALPHA_A_CTRL.
image output = s01_alpha × s1_pixel' + s10_alpha × s0_pixel'
alpha output = s10_alpha × s0_alpha'' + s01_alpha × s1_alpha''

36.4.13 Color Key

The color key function is provided to create transparent effects on the output pixel.

Color keying is applied on the input pixels after they are converted to 8-bits for each red, green, and blue color channels (color keys are not applied directly to 16-bit pixel formats but to their corresponding 24-bit representation). A color key range is programmable for both PS and AS pixels. If the PS 24-bit pixel is within the PS color key range, then AS is passed through the pixel pipeline. In this case, alpha blending does NOT occur. Conversely, if PS is within the AS color key range, then PS is passed via the PXP data pipeline. If both PS and AS color key tests pass, then the back ground color register is passed onto following PXP processing components in the pipeline.

The condition for color keying to be satisfied is:
CK0.r.low <= PS.r <= CK0.r.high
CK0.g.low <= PS.g <= CK0.g.high
CK0.b.low <= PS.b <= CK0.b.high

For example, if the "red" 8-bit value for the PS pixel (or PS.r) is between the color key low and high values (CK0.r.l and CK0.r.h), the condition is true for the red color plane. When ALL three color planes meet this condition, then only the PS pixel is loaded into the output register.

To disable color keying, program the low color key register value to 0xff and the high value to 0x00. This will guarantee that the color key range test will never be true.

### 36.4.14 Rotation

There is a single rotation resource integrated into the PXP. The location of this resource within the PXP data path is programmable. Rotation can occur after compositing the AS and PS buffers in the output stage.

As an alternative configuration, the PS buffer can be rotated and later composited with the AS surface that is not rotated. There is a single configuration bit that provides the configuration of where rotation is implemented within the PXP.

To rotate graphics, the hardware must read pixels in one direction across a frame buffer and write them in an alternate orientation. For the 90 and 270 degree cases, this means that lines of pixels must either be read or written vertically in a frame buffer.

![Figure 36-10. Rotation Read and Write](image-url)
In order to rotate efficiently, multiple columns must be rotated to enable the engine to both fetch and store bursts of pixels, thus improving memory performance. The simplest method of doing this is to operate on square blocks of pixels. To rotate the image, each sub-block of pixels must be rotated by the required rotation angle.

![Source buffer](image)

![Destination buffer](image)

When multiple lines are read from the source buffer, data can be both read and written as bursts to the memory controller. In this example, photos are read in a 4x4 pixel block and rotated, improving memory efficiency.

**Figure 36-11. Rotated Sub-blocks**

To manage the rotation process, the source image can be broken into a grid of sub-blocks that have coordinates as shown in the diagram below. In addition to rotating the sub-block, each block must be translated to a new coordinate location. For each of the rotation angles (0, 90, 180, 270), it is possible to define a simple algorithm for computing the new translated grid address. The hardware must then simply compute the memory address from the base grid address for both load and store operations.
When the image is broken into a grid and sub-blocks, each sub-block can be numbered with a coordinate. In addition to being rotated, each sub-block is translated to a new grid coordinate. The new coordinate can easily be calculated from the source coordinate and the angle of rotation.

**Figure 36-12. Grid of Sub-Blocks with Coordinates**

In order to balance the requirements of reasonable burst sizes to the memory controller as well as keep the hardware storage requirements to a minimum, the blending/rotation engine will operate on either 8x8 or 16x16 pixel blocks. When using the Rotate engine with the input fetch engine, you need to program the input fetch engine to work in 8x8 block mode.

**NOTE**

An important artifact of the PXP is when rotating a source image and the output is NOT divisible by the block size selected. The output engine essentially truncates any output pixels after the desired number of pixels has been written. Since the output buffer is written as a horizontal row of blocks, the incorrect pixels could be truncated and the final output image can look shifted. In the case where the block size is programmed to 8x8, and the output size that is programmed is 12x12, then there is a remainder of 4 pixels that will be truncated in either the X and/or Y axis when the PXP operation is complete. The output will be shifted by 4 pixels in this example. To compensate for this, the source base address needs to be adjusted so the correct pixels get truncated and the image does not look shifted. In this example, with 90 degrees of rotation, the PS base address should be adjusted by 4 times the actual PS base address -(4*pitch).
36.4.15 Output Buffer

The output buffer engine accepts data from the PXP pixel pipeline and issues requests to transfer the output pixels to external DRAM or the internal SRAM double buffer row of blocks.

36.4.16 Address calculator

Each of the blocks will manage its own fetch address using a common address calculator block that computes real addresses from a base address and relative block offset from the base.

Each block will then perform the multiple line fetches (or stores) required to perform the operation. This hides all the address buffer computations from the processing blocks and allows each block to simply track the coordinate of the block it is working on.

36.4.17 Block size selection

The PXP can be configured to process blocks that are either 8x8 pixels or 16x16 pixels with the REG_CTRL[BLOCK_SIZE] control bit.

When selecting a 16x16 pixel block size, the accesses to fetch AS and PS images and write the final frame buffer are more efficient since twice as much data is requested and processed per memory request.

When optimizing the system for memory bandwidth and image processing time, configure the PXP to process 16x16 pixel blocks.

36.4.18 Interlaced Video Support

The PXP has some minimal ability to generate interlaced video content from a progressive source. There two available options, based on the bandwidth requirements and how software is managing video frames.

The PXP can either interlace on the input side (by reading every other line of input data) or on the output side (by writing the individual lines of video into two separate fields). Generally, output interleaving should be used since it is the most flexible mode (it allows scaling and full overlay support) and it only requires a single pass of the PXP to generate two separate output fields.
Input interleaving can be beneficial in cases where the PXP is running at 60fps, since it requires fewer fetches to produce the output data. There is no direct hardware support for input interleaving, in that, there is no configuration bit that can be set to alter how the PXP processes a frame for input interleaving. Input interleaving is achieved by simply setting the source frame buffer pitch value to twice the value it would normally be set to for the equivalent progressive frame. The output parameters also need to be consistent with the desired processing effect. For example, the vertical resolution would be set to account for the reduced resolution to process the interlaced input buffers.

### 36.4.19 LCDIF Handshake

The PXP and LCDIF support a mode where the internal SRAM can be used for the frame buffer to minimize external memory bandwidth required.

This is accomplished by creating two buffers in SRAM, a double buffer row of blocks, where each correspond to 8/16-lines of the frame buffer. The buffers must be consecutive and allocated as a single block of data.

![Buffer in OCRAM](image)

**Figure 36-13. Buffer in OCRAM**

The storage required can be calculated for an 8x8 block size as

- storage = 16 (lines) * rotated_row_length * pixel_size

and for 16x16 block size as

- storage = 32 (lines) * rotated_row_length * pixel_size

where pixel_size = 4 for 32bpp or 2 for 16bpp modes. The following table lists the storage requirements for common image sizes using 8x8 block size:

<table>
<thead>
<tr>
<th>Image Size</th>
<th>Storage (16bpp)</th>
<th>Storage (24bpp)</th>
<th>Storage (32bpp)</th>
</tr>
</thead>

<td>20KB</td>
<td>30KB</td>
<td>40KB</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
The following diagram shows how the minimal rotation buffer would be organized. As the engine and LCD progress down the image, they continually swap roles of filling and emptying each eight-line buffer.

![Minimal Rotation Buffer Organization](image)

The LCD controller (our output scanner) would read one buffer as the blending rotation angle files the second buffer. In this manner, the entire rotated frame buffer need not be written to memory.

**Figure 36-14. Minimal Rotation Buffer Organization**

When this mode is enabled, the PXP will process one row of pixel blocks and write the results to the first SRAM buffer (buffer 0). The PXP will then alternate between writing subsequent rows to buffer 0 and buffer 1. After the PXP generates the data for one buffer, the LCDIF will begin reading that buffer and send the contents to the display device. After the LCDIF finishes reading a buffer, it will start displaying from the other buffer while the PXP continues filling the previously processed buffer.
To accomplish the buffer sharing, the PXP and LCDIF will maintain buffer status using a pair of handshake signals. When a buffer is filled by the PXP, it will assert the `pxp_lcdif_bx_ready` (where x is 0 or 1) signal to indicate to the LCDIF that the buffer has valid data. The LCDIF will then release the buffer by asserting the `lcdif_pxp_bx_done` signal.

The basic protocol is shown in the diagram below:

![Buffer Sharing Diagram](image)

**Figure 36-15. PXP and LCDIF Buffer Sharing**

**Figure 36-16. Buffer Sharing Protocol**
The PXP will continue to assert the bx_ready signal until the corresponding bx_done signal is sampled high for one clock cycle. It will then deassert the bn_ready until the next time the buffer has been filled. After the PXP samples the bx_done signal asserted, it is free to begin filling the buffer with the next block size lines of display data. If a buffer has not been released when the PXP is ready to process data for that buffer, it will suspend rendering operations until the buffer has been released by the LCDIF.

### 36.4.20 LCDIF Abort

When the memory subsystem is not loaded, the PXP should be able to render the buffers faster than the LCDIF can drain the buffers.

It is possible under some scenarios (high LCDIF output rates with high memory latency) that the PXP may not be able to keep up with the LCDIF, even in the SRAM mode of operation. When this happens, the LCDIF will signal that it has completed one of the buffers before the other has been rendered by the PXP. This condition will be detected by the PXP's control logic as an "LCDIF Abort", which will cause the PXP to abort processing in the current row and proceed to the following row. It will acknowledge the abort to the LCDIF by raising the buffer_ready signal for the current buffer to enable the LCDIF to begin displaying the partially-filled buffer. While an abort will create artifacts in the video display, it does minimize the artifacts by limiting them to the remaining pixels blocks in the current row versus ruining the entire frame buffer.

![Figure 36-17. LCDIF Abort](image)

### 36.4.21 Theory of Operation

The PXP can be used to accelerate graphics operations by offloading graphics processing from the processor. The block can perform alpha blending and color key substitution on two RGB graphics buffers.

The PXP is organized as having a processed surface (PS) and an alpha surface (AS) that can be blended with the processed surface. There are no restrictions on the location of the AS or PS within the output surface (OS). As the PXP processes NxN blocks, operations...
are performed on a pixel by pixel basis. The AS and PS pixels are alpha blended, color
to key, process by CSC resources as individual pixel components. This allows efficient
block processing with supporting arbitrary alignment for both the AS and PS surfaces.
The resulting pixel block is then written to the corresponding block in the output buffer.

36.4.22  Pixel Handling

All pixels are internally represented as 32-bit values regardless of input or output pixel
formats. The pixels get converted in the AS and PS buffer engines to 24-bit pixel values.
There is also an 8-bit alpha value at stages up to the alpha blender within the PXP for
blending within the RGB color space. Compositing of AS and PS images can only occur
in the RGB color space. If compositing is not required, then YUV pixels can be
transferred and processed at all PXP pixel resource components. The color orientation of
pixels within the PXP can be controlled by the CSC1 resource.

For RGB, input pixels are converted into 32-bit pixel values using the following rules for
both AS and PS:

1. 32-bit ARGB8888 pixels are read directly with no conversion.
2. 32-bit RGB888 pixels are assumed to have an alpha value of 0xFF (full opaque).
3. 6-bit RGB565 and RGB555 values are expanded into the corresponding 24-bit color
   space and assigned an alpha value of 0xFF (opaque). The expansion process
   replicates the upper pixel bits into the lower pixel bits (for instance a 16-bit RGB555
   triplet of 0x1F/0x10/0x07 would be expanded to 0xFF/0x84/0x39).
4. 16-bit RGB1555 values are expanded into the corresponding 24-bit color space and
   assigned an alpha value of either 0x00 or 0xFF, based on the 1-bit alpha value in the
   pixel. The ALPHA_MULTIPLY function is useful in this scenario to allow scaling
   of the opaque pixels to a semi-transparent value.

Alpha values can be passed through the entire PXP data path and output in ARGB888
and ARGB555 pixel modes. Also, output pixels can be assigned an alpha value using the
REG_OUT_CTRL[ALPHA] register. 16-bit pixels values are formed from the most
significant bits of the 24-bit pixel values.

When YUV/YCbCr output formats are selected, all pixels are internally represented as
either RGB or YUV pixels values.
### 36.4.23 Output Buffer Composition

The output buffer will be rendered by composing each pixel block from the associated PS and AS buffers.

The AS pixel buffer can be blended or color-keyed with the associated data from the PS buffer (either the PS image pixels or REG_PS_BACKGROUND register based on PS programmed coordinates).

![Output Buffer Composition](image)

**Figure 36-18. Output Buffer Composition**

### 36.4.24 PS Image Processing

As the PXP processes image buffers, it iterates over the output buffer by fetching the corresponding input buffer blocks and processing the pixels embedded in these.
### 36.4.25 Letterboxing

At each pixel coordinate, the control logic determines if the PS pixel (argument also applies to AS pixels) will be used in rendering the output pixel.

This is determined by checking the output pixel's coordinates against the REG_OUT_PS_ULC and REG_OUT_PS_LRC (ULC and LRC in short) register contents. For pixels outside this region, the PS pixel will be loaded with the pixel value from REG_PS_BACKGROUND, which can be used to effectively control the letterboxing color. There are no block size or block boundary restrictions when setting the ULC or LRC for either the AS or PS. The only restriction is that the ULC and LRC are within the OUT LRC extents.

![PS Image](image)

The region outside the PS coordinates will be filled with the value specified in the PSBACKGROUND register.

**Figure 36-19. OUT Buffer**

### 36.4.26 Clipping source images

A subset of the PS buffer can be used in rendering the output buffer. The PXP_PS_BUF register can indicate an offset into the PS buffer that will be used for display within the OUTPUT buffer.

The pixel at the address defined in the PXP_PS_BUF register will be the pixel that is displayed at the pixel coordinate indicated by PXP_OUT_PS_ULC within the output buffer. Essentially, the PXP_PS_BUF register can be used to establish an offset into the PS buffer thus clipping all PS buffer pixels that are at a lower address. The PXP_PS_PITCH will always indicate the number of bytes that are vertically adjacent in
the PS buffer. The settings in the PXP_PS_BUF, PXP_OUT_PS_ULC, and PXP_OUT_PS_LRC will determine the subset of the PS buffer, or clipped PS source buffer, that will be used in the output buffer.

It is important to note that when scaling the PS buffer, the coordinates of the PS buffer within the output buffer need to be consistent with the scaling factors and original PS buffer size.

![Figure 36-20. PS Buffer Scaling](image)

When sourcing a subset of the PS image, it should fall completely within the PS buffer to avoid displaying incorrect data. The following conditions should be met:

\[
x_{\text{base_addr}} + x_{\text{scale}} \times (\text{LRC}_X-\text{ULC}_X) \leq \text{PS}\_\text{pitch}
\]
\[
y_{\text{base_addr}} + y_{\text{scale}} \times (\text{LRC}_Y-\text{ULC}_Y) \leq \text{PS}\_\text{size}
\]

The PXP hardware does not check for these conditions and will render the image as programmed. The following case could indicate invalid programming parameters for the PXP:
36.4.27 Color Key Processing

Pixels may be made transparent to the corresponding AS by using the PS color key registers.

If a PS pixel matches the range specified by the REG_PS_COLORKEYLOW and REG_PS_COLORKEYHIGH registers, the pixel from the associated AS will be displayed. If no AS is present for the pixel, a black pixel will be generated since the default AS pixel is 0x00000000 (transparent black pixel).

The most common use for this is when a bitmap does not support an alpha-field or for applications such as "green screen" where an image is substituted for a solid background color.
Figure 36-22. The PS image (player) and AS image (stadium)

The green portion of the background image can be color keyed to display the contents of the AS buffer for locations that match the color range. For this example, the color range is:

PS Colorkey: 00<R<80 70<G<ff 00<B<80

The resulting image becomes:

Figure 36-23. Resulting Image
36.4.28  In Place Processing (PS buffer is destination buffer)

The PXP also has the ability to process an image and write the resulting buffer back to the original PS buffer. This is referred to as "in place" rendering.

This could be useful for basic blit operations into the PS buffer. IN_PLACE operations are achieved by programming the OUT base address to the pixel location in the PS buffer that marks the upper left pixel of the update region. The actual region that is updated should be indicated by programming the ULC = (0,0) and the LRC = (X,Y). The region bounded by the coordinates will be updated, and the rest of the PS buffer will not be modified.

36.4.29  Alpha Surface (AS) Processing

The AS surface has a complete set of registers that determines how the AS effects the final OUT surface.

Most of the registers that exist for the PS surface also are defined for the AS surface where applicable. This is provided to replicate the SW interface for each PS and AS processes.

36.4.30  Alpha Handling

Alpha values in the AS are embedded in the source image pixels. For AS pixel formats that do not support an alpha value, the pixel is assigned an alpha value of 0xFF (opaque).

This can be modified by the AS control by setting either the ALPHA_MULTIPLY or ALPHA OVERRIDE bit in the associated AS_CTRL register. If ALPHA_MULTIPLY is enabled, the 8-bit ALPHA value from the AS_CTRL register is multiplied by the source alpha before blending with the PS image. If the ALPHA_OVERRIDE bit is set, the 8-bit ALPHA value is simply substituted for the pixel.

36.4.31  Color Key Processing (AS_CTRL)

The AS_CTRL register also contains an ENABLE_COLORKEY bit that can be used to enable or disable color key substitution for the AS.
When enabled, the pixel values are compared to the ASCOLORKEYLOW and ASCOLORKEYHIGH registers to determine if a match has occurred. When an AS pixel matches the color key range, the pixel from the AS image is considered transparent and the corresponding PS pixel is rendered. If both the PS and AS pixels match their corresponding color key ranges, the AS pixel is displayed unmodified.

AS color keys are handled in a manner similar to PS color keys. The same images used in the PS color key example could be used with the images swapped. In this case, matches on the AS image to the ASCOLORKEY register would display the PS pixels.

### 36.5 Output Image Processing

Several PXP options affect the resulting output image.

#### 36.5.1 Output Image Size

The PXP generates an output image in the resolution programmed by the REG_OUT_LRC. As the PXP processes pixels, it iterates over the NxN blocks (in output scan-block order) based on the final image resolution.

#### 36.5.2 Output Format

The result of PXP operations are written to the buffer pointed to by the REG_OUT_BUF/REG_OUT_BUF2 registers. The pixel format is controlled by the REG_OUT_CTRL[FORMAT] bit-field.

32-bit pixels are formed directly from the internal 24-bit representations and 16-bit pixel formats are generated by truncating the internal 24-bit values to the appropriate number of bits. For formats supporting an alpha value, the PXP assigns the alpha using the 8-bit value in the REG_OUT_CTRL[ALPHA] field. For ARGB1555, the most significant alpha bit is appended to the output pixel. Also, for ARGB4444, the most significant nibble is appended to the output pixel. Single and dual buffer YUV output formats are also available. Since each pixel in the data path is represented by a full YUV444 24bpp value, decimation reduces the output in cases of YUV422/420 output formats.
36.5.3 Rotation/Flip operations

The PXP supports four rotation angles in conjunction with vertical and horizontal flip options. The flip operations effectively take place before the rotation.

Rotations of 0, 90, 180, and 270 degrees are supported and any combination of rotation and flip are supported. There is no performance difference between any of these modes of operation.

36.6 Queuing PXP transactions

The PXP supports a primitive ability to queue up one operation while the current operation is running. This is enabled through the use of the REG_NEXT register.

When this register is written, it enables the PXP to reload its current register contents with the data found at the location pointed to by this address when it completes processing of the current frame. This feature may be useful in helping to reduce the interrupt latency in servicing the PXP, especially in cases where the PXP and LCDIF are using the on-chip SRAM buffer handshake (since the PXP must begin generating next frame data immediately).

If the PXP is idle when the REG_NEXT register is written, the PXP treats this as an indication that it should immediately load the values at the pointer and begin processing the frame. This ability should allow software to use the same routines when programming the PXP (so that the first frame doesn't differ from subsequent frames).

When loading values from the NEXT register, all registers in the PXP are reloaded. Some register loads have no effect.

After writing the REG_NEXT register, the PXP will set the REG_NEXT[ENABLED] bit of the REG_NEXT register to indicate that the next command has been queued. Software should first check the status of this bit to ensure that a previous command has not been enabled. Likewise, after programming the first frame in a sequence of frames, software should poll this bit until it is sampled logic 1'b0 before queuing the next operation.

The PXP will issue interrupts from frames as they complete, regardless of whether they were started by writing the control registers directly or using the REG_NEXT register. When software receives an interrupt, it should check/clear the PXP's status register as normal, poll the REG_PXP[ENABLED] bit, and then issue the next operation. A queued operation may be cancelled by issuing a CLEAR operation to the REG_PXP[ENABLED] register bit. The SET and TOGGLE operations should never be used with this register.
36.7 Error Handling

The PXP does minimal checking on the control registers, so it is important that these are correctly specified. The PXP does monitor the bus transactions for errors and will report errors in the status register.

Upon receipt of a bus error, the PXP will set the ERROR interrupt and abort any further operations. Bus errors can be generated from any system access that results in an error response returned from the internal SIM Bus errors in the PXP are signaled as either a read or a write error, but do not indicate the failing address. Software may deduce the failing address from the current block status indicators.

36.7.1 Known PXP Limitations/Issues

The PXP has the following known limitations:

1. When using the NEXT register, the interrupt enable setting should remain the same for all frames. If not, the PXP will change the interrupt enable register value and possible cause the loss of an interrupt.
2. Rotations of 180/270 are not supported when performing LCD handshakes

### 36.8.1 Control Register 0 (PXP_CTRL0)

The CTRL register contains controls for the PXP module.

PXP_CTRL: 0x000
PXP_CTRL_SET: 0x004
PXP_CTRL_CLR: 0x008
PXP_CTRL_TOG: 0x00C

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

**EXAMPLE**

```c
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```
PXP Memory Map/Register Definition

Address: \(402B_{16}.4000h\) base + 0h offset + \((4d \times i)\), where \(i=0d\) to \(3d\)

### PXP_CTRLn field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 SFTRST</td>
<td>Set this bit to zero to enable normal PXP operation. Set this bit to one (default) to disable clocking with the PXP and hold it in its reset (lowest power) state. This bit can be turned on and then off to reset the PXP block to its default state.</td>
</tr>
<tr>
<td>30 CLKGATE</td>
<td>This bit must be set to zero for normal operation. When set to one it gates off the clocks to the block.</td>
</tr>
<tr>
<td>29 RSVD4</td>
<td>Reserved, always set to zero.</td>
</tr>
<tr>
<td>28 EN_REPEAT</td>
<td>Enable the PXP to run continuously. When this bit is set, the PXP will repeat based on the current configuration register settings. If this bit is not set, the PXP will complete the process and enter the idle state ready to accept the next frame to be processed. This bit should be set when the LCDIF handshake mode is enabled so that the next frame is automatically generated for the next screen refresh cycle. If it is not set and the handshake mode is enabled, the CPU will have to initiate the PXP for the next refresh cycle. When the PXP NEXT feature is used, it has priority over the REPEAT mode, in that the new register settings are fetched first, and then the next PXP operation will continue.</td>
</tr>
<tr>
<td>27–24 RSVD3</td>
<td>Reserved, always set to zero.</td>
</tr>
<tr>
<td>23 BLOCK_SIZE</td>
<td>Select the block size to process.</td>
</tr>
<tr>
<td>22 ROT_POS</td>
<td>This bit controls where rotation will occur in the PXP datapath. Setting this bit to 1'b0 will place the rotation resources at the output stage of the PXP data path. Image compositing will occur before pixels are processed for rotation. Setting this bit to a 1'b1 will place the rotation resources before image composition. Only the PS can be rotated in this configuration and AS will not be rotated.</td>
</tr>
<tr>
<td>21–12 RSVD1</td>
<td>Reserved, always set to zero.</td>
</tr>
<tr>
<td>11 VFLIP</td>
<td>Indicates that the output buffer should be flipped vertically (effect applied before rotation).</td>
</tr>
<tr>
<td>10 HFLIP</td>
<td>Indicates that the output buffer should be flipped horizontally (effect applied before rotation).</td>
</tr>
<tr>
<td>9–8 ROTATE</td>
<td>Indicates the clockwise rotation to be applied at the output buffer. The rotation effect is defined as occurring after the FLIP_X and FLIP_Y permutation.</td>
</tr>
<tr>
<td>7–5 Reserved</td>
<td>This read-only field is reserved and always has the value 0.</td>
</tr>
<tr>
<td>4 ENABLE_LCD_HANDSHAKE</td>
<td>Enable handshake with LCD controller. When this is set, the PXP will not process an entire framebuffer, but will instead process rows of NxN blocks in a double-buffer handshake with the LCDIF. This enables the use of the onboard SRAM for a partial frame buffer.</td>
</tr>
<tr>
<td>3 Reserved</td>
<td>This field is reserved.</td>
</tr>
<tr>
<td>2 NEXT_IRQ_ENABLE</td>
<td>Next command interrupt enable. When set, the PXP will issue an interrupt when a queued command initiated by a write to the PXP_NEXT register has been loaded into the PXP's registers. This interrupt also indicates that a new command may now be queued.</td>
</tr>
</tbody>
</table>

Table continues on the next page...
### PXP_CTRL field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IRQ_ENABLE</td>
<td>Interrupt enable. NOTE: When using the PXP_NEXT functionality to reprogram the PXP, the new value of this bit will be used and may therefore enable or disable an interrupt unintentionally.</td>
</tr>
<tr>
<td>ENABLE</td>
<td>Enables PXP operation with specified parameters. The ENABLE bit will remain set while the PXP is active and will be cleared after the current operation completes. Software should use the IRQ bit in the PXP_STAT when polling for PXP completion.</td>
</tr>
</tbody>
</table>

### 36.8.2 Status Register (PXP_STATn)

The PXP Interrupt Status register provides interrupt status information.

- **PXP_STAT**: 0x010
- **PXP_STAT_SET**: 0x014
- **PXP_STAT_CLR**: 0x018
- **PXP_STAT_TOG**: 0x01C

This register provides PXP interrupt status and the current X/Y block coordinate that is being processed.

**EXAMPLE**

```c
PXP_STAT_CLR(BM_PXP_STAT_IRQ);  // clear CSC interrupt
```

Address: 402B_4000h base + 10h offset + (4d × i), where i=0d to 3d

---

```plaintext
Bit 31 30 29 28 27 26 25 24 | 23 22 21 20 19 18 17 16

<tr>
<td>1 AXI_WRITE_ERROR</td>
<td>Indicates P XP encountered an AXI write error and processing has been terminated.</td>
</tr>
<tr>
<td>0 IRQ</td>
<td>Indicates current P XP interrupt status. The IRQ is routed through the pxp_irq when the IRQ_ENABLE bit in the control register is set.</td>
</tr>
</tbody>
</table>

36.8.3 Output Buffer Control Register (P XP_OUT_CTRLn)

The OUT_CTRL register contains controls for the Output Buffer.

P XP_OUT_CTRL: 0x020
The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

EXAMPLE

```c
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);
```

Address: 402B_4000h base + 20h offset + (4d × i), where i=0d to 3d

![Memory Map Diagram]
### PXP_OUT_CTRL\_n field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–24 ALPHA</td>
<td>When generating an output buffer with an alpha component, the value in this field will be used when enabled to override the alpha passed through the pixel data pipeline.</td>
</tr>
<tr>
<td>23 ALPHA_OUTPUT</td>
<td>Indicates that alpha component in output buffer pixels should be overwritten by PXP_OUT_CTRL[ALPHA]. If 0, retain their alpha value from the computed alpha for that pixel.</td>
</tr>
<tr>
<td>22–10 RSVD1</td>
<td>Reserved, always set to zero.</td>
</tr>
<tr>
<td>9–8 INTERLACED_OUTPUT</td>
<td>Determines how the PXP writes it's output data. Output interlacing should not be used in conjunction with input interlacing. Splitting frames into fields is most efficient using output interlacing. 2-plane output formats AND interlaced output is NOT supported.</td>
</tr>
<tr>
<td>7–5 RSVD0</td>
<td>Reserved, always set to zero.</td>
</tr>
<tr>
<td>FORMAT</td>
<td>Output framebuffer format. The UV byte lanes are synonymous with CbCr byte lanes for YUV output pixel formats. For example, the YUV2P420 format should be selected when the output is YCbCr 2-plane 420 output format.</td>
</tr>
<tr>
<td></td>
<td>0x0 PROGRESSIVE — All data written in progressive format to the OUTBUF Pointer.</td>
</tr>
<tr>
<td></td>
<td>0x1 FIELD0 — Interlaced output: only data for field 0 is written to the OUTBUF Pointer.</td>
</tr>
<tr>
<td></td>
<td>0x2 FIELD1 — Interlaced output: only data for field 1 is written to the OUTBUF2 Pointer.</td>
</tr>
<tr>
<td></td>
<td>0x3 INTERLACED — Interlaced output: data for field 0 is written to OUTBUF and data for field 1 is written to OUTBUF2.</td>
</tr>
<tr>
<td></td>
<td>0x0 ARGB8888 — 32-bit pixels</td>
</tr>
<tr>
<td></td>
<td>0x4 RGB888 — 32-bit pixels (unpacked 24-bit pixel in 32 bit DWORD.)</td>
</tr>
<tr>
<td></td>
<td>0x5 RGB888P — 24-bit pixels (packed 24-bit format)</td>
</tr>
<tr>
<td></td>
<td>0x8 ARGB1555 — 16-bit pixels</td>
</tr>
<tr>
<td></td>
<td>0x9 ARGB4444 — 16-bit pixels</td>
</tr>
<tr>
<td></td>
<td>0xC RGB565 — 16-bit pixels</td>
</tr>
<tr>
<td></td>
<td>0x10 YUV1P444 — 32-bit pixels (1-plane XYUV unpacked)</td>
</tr>
<tr>
<td></td>
<td>0x12 UYY1P422 — 16-bit pixels (1-plane U0,Y0,V0,Y1 interleaved bytes)</td>
</tr>
<tr>
<td></td>
<td>0x13 VYY1P422 — 16-bit pixels (1-plane V0,Y0,U0,Y1 interleaved bytes)</td>
</tr>
<tr>
<td></td>
<td>0x14 Y8 — 8-bit monochrome pixels (1-plane Y luma output)</td>
</tr>
<tr>
<td></td>
<td>0x15 Y4 — 4-bit monochrome pixels (1-plane Y luma, 4 bit truncation)</td>
</tr>
<tr>
<td></td>
<td>0x18 YUV2P422 — 16-bit pixels (2-plane UV interleaved bytes)</td>
</tr>
<tr>
<td></td>
<td>0x19 YUV2P420 — 16-bit pixels (2-plane UV)</td>
</tr>
<tr>
<td></td>
<td>0x1A YVU2P422 — 16-bit pixels (2-plane VU interleaved bytes)</td>
</tr>
<tr>
<td></td>
<td>0x1B YVU2P420 — 16-bit pixels (2-plane VU)</td>
</tr>
</tbody>
</table>

### 36.8.4 Output Frame Buffer Pointer (PXP_OUT_BUF)

Output Framebuffer Pointer. This register points to the beginning of the output frame buffer. This pointer is used for progressive format and field 0 when generating interlaced output.
This register is used by the logic to point to the current output location for the output frame buffer.

**EXAMPLE**

```c
PXP_OUT_BUF_WR( buffer );
```

Address: 402B_4000h base + 30h offset = 402B_4030h

</tbody>
</table>

### 36.8.5 Output Frame Buffer Pointer #2 (PXP_OUT_BUF2)

Output Framebuffer Pointer #2. This register points to the beginning of the output frame buffer for either field 1 when generating interlaced output or for the UV buffer when in YUV 2-plane output modes. Both interlaced output AND 2-plane output modes are not supported in a single PXP operation. This register is not used as the pointer to the second buffer when in LCDIF_HANDSHAKE mode.

This register is used by the logic to point to the current output location for the field 1 or UV output frame buffer.

**EXAMPLE**

```c
PXP_OUT_BUF_WR( field0 );  // buffer for interlaced field 0
PXP_OUT_BUF2_WR( field1 ); // buffer for interlaced field 1
```

Address: 402B_4000h base + 40h offset = 402B_4040h

36.8.6 Output Buffer Pitch (PXP_OUT_PITCH)

This register contains the output buffer pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in output pixel address calculations.

**EXAMPLE**

```c
PXP_OUT_PITCH_WR( 68 * 4 );  // The output buffer pitch is 68 pixels times 32 bits per pixel
```

Address: 402B_4000h base + 50h offset = 402B_4050h

</tr>
</tbody>
</table>

36.8.7 Output Surface Lower Right Coordinate (PXP_OUT_LRC)

This register contains the size, or lower right coordinate, of the output buffer NOT rotated. It is implied that the upper left coordinate of the output surface is always [0,0]. When rotating the framebuffer, the PXP will automatically swap the X/Y, or WIDTH/HEIGHT, to accomodate the rotated size.

This register sets the size of the output frame buffer in pixels, not blocks. The frame buffer need not be a multiple of NxN pixels. Partial blocks will be written for output frame buffer sizes that are not divisable by N pixels in either dimension.

**EXAMPLE**

```c
PXP_OUT_LRC[X]=319;   // set width of output frame buffer to 320 pixels
PXP_OUT_LRC[Y]=243;  // set height of output frame buffer to 244 pixels which is not divisible by block size N
PXP_OUT_LRC_WR( BF_PXP_OUT_LRC_X(319)  |  BF_PXP_OUT_LRC_Y(243) );
```

</tr>
</tbody>
</table>

36.8.8 Processed Surface Upper Left Coordinate (PXP_OUT_PS_ULC)

This register contains the upper left pixel coordinate for the Processed Surface in the OUTPUT buffer.

This register contains the upper left coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. If the value of the PXP_OUT_PS_ULC is greater than the PXP_OUT_LRC, then no PS pixels will be fetched from memory, but only PXP_PSBACKGROUND pixels will be processed by the PS engine. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP_OUT_LRC extents will use the PS to render pixels into the output buffer.

**EXAMPLE**

PXP_OUT_PS_ULC_WR(0x0002_0002); // Processed Surface upper left coordinate at (X,Y) = 2,2. The PS surface will not effect pixels in the first and second row and column of the output buffer.

</tbody>
</table>

### 36.8.9 Processed Surface Lower Right Coordinate (PXP_OUT_PS_LRC)

This register contains the lower right extent for the Processed Surface in the OUTPUT buffer.

This register contains the lower right coordinate of the Processed Surface in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the PS upper left coordinates, less than or equal to the PS lower right coordinates, and within the PXP_OUT_LRC extents will use the PS to render pixels into the output buffer.

**EXAMPLE**

```c
PXP_OUT_PS_ULC_WR(0, 0x03FF_03FF); // With this UL/LR pair of pixel coordinates, only one pixel at OUT[X,Y]=1023,1023 will use the PS to contribute to its value.
PXP_OUT_PS_LRC_WR(0, 0x03FF_03FF);
```

### 36.8.10 Alpha Surface Upper Left Coordinate (PXP_OUT_AS_ULC)

This register contains the upper left location for the Alpha Surface in the output buffer.

This register contains the upper left coordinate of AS in the output frame buffer (in pixels). Values that are within the PXP_OUT_LRC X,Y extents are valid. The lowest valid value for these fields is 0,0. Pixel locations that are greater than or equal to the upper left coordinates will use the AS to render pixels in the output buffer.

**EXAMPLE**

```
PXP_OUT_AS_ULC_WR(0,0x0001_0001); // Alpha Surface upper left coordinate at (X,Y) = 1,1. The AS surface will not effect pixels in the first row or first column of the output buffer.
```

Address: 402B_4000h base + 90h offset = 402B_4090h

#### 36.8.12 Processed Surface (PS) Control Register (PXP_PS_CTRLn)

The PS_CTRL register contains controls for the Processed Surface Buffer.

- **PXP_PS_CTRL**: 0x0B0
- **PXP_PS_CTRL_SET**: 0xb4
- **PXP_PS_CTRL_CLR**: 0xB8
- **PXP_PS_CTRL_TOG**: 0xBC

The Control register contains the primary controls for the PXP block. The present bits indicate which of the sub-features of the block are present in the hardware.

**EXAMPLE**

```c
PXP_CTRL_SET(BM_PXP_CTRL_SFTRST);  
PXP_CTRL_CLR(BM_PXP_CTRL_SFTRST | BM_PXP_CTRL_CLKGATE);  
```

Address: 402B_4000h base + B0h offset + (4d × i), where i=0d to 3d

</table>
36.8.13 PS Input Buffer Address (PXP_PS_BUF)

PS Input Buffer Address. This should be programmed to the starting address of the RGB data or Y (luma) data for the PS plane.

This register contains the pointer to the Luma/RGB buffer. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

PXP_PS_BUF_WR(image_rgb); // RGB image
PXP_PS_BUF_WR(image_y);   // Y (luma) image data
PXP_PS_UBUF_WR(image_u);  // U (Cb) image data
PXP_PS_VBUF_WR(image_v);  // V (Cr) image data

Address: 402B_4000h base + C0h offset = 402B_40C0h

36.8.14 PS U/Cb or 2 Plane UV Input Buffer Address (PXP_PS_UBUF)

PS Chroma (U/Cb/UV) Input Buffer Address. This register points to the beginning of the PS U/Cb input buffer. In two plane operation, this register points to the beginning of the PS UV chroma input buffer.

This register contains the pointer to the Chroma U/Cb or 2 plane UV buffer. This register is unused when processing 1-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

EXAMPLE

PXP_PS_BUF_WR(image_y);   // Y (luma) image data
PXP_PS_UBUF_WR(image_u);  // U (Cb) image data
PXP_PS_VBUF_WR(image_v);  // V (Cr) image data
Address: 402B_4000h base + D0h offset = 402B_40D0h

#### 36.8.15 PS V/Cr Input Buffer Address (PXP_PS_VBUF)

PS Chroma (V/Cr) Input Buffer Address. This register points to the beginning of the PS V/Cr input buffer. In one or two plane operation, this register is not used. In monochrome modes Y8 and Y4, the low 16 bits are used as the U/V data in the datapath instead of sourcing U/V data from external buffers. In this case, it represents a fixed value for U/V data.

This register contains the pointer to the Chroma V/Cr buffer. For Y8/Y4 modes, the low 16 bits are used as the monochrome U and V values in the data path. Bits [15:8] represent the U data byte, and bits [7:0] represent the V data byte. Other than with Y8/Y4 input buffer formats, this register is unused when processing 1 or 2-plane buffer formats. If the application requires an offset into the PS buffer, then this address can be set so that the desired offset is achieved. Any byte address is valid. For best performance, 64B alignment is recommended.

**EXAMPLE**

```c
PXP_PS_BUF_WR(image_y); // Y (luma) image data
PXP_PS_UBUF_WR(image_u); // U (Cb) image data
PXP_PS_VBUF_WR(image_v); // V (Cr) image data
```

Address: 402B_4000h base + E0h offset = 402B_40E0h

</tbody>
</table>
36.8.16 Processed Surface Pitch (PXP_PS_PITCH)

This register contains the processed surface pitch in bytes.

Any byte value will indicate the vertical pitch of the PS source frame buffer. This value will be used in PS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input PS surface. For multi-plane formats, the Y buffer pitch should be programmed. For 2-plane YUV422, the UV pitch is the same as the Y pitch. For 3-plane YUV422, the U and V pitch is 1/2 the Y pitch. For 2-plane YUV420, the UV pitch is 1/2 the Y pitch. For 3-plane YUV420, the U and V pitch is 1/4 the Y pitch. All source buffers should comply with these U and V resolution reductions with respect to their Y source buffers.

**EXAMPLE**

```
PXP_PS_PITCH_WR( 64 * 4 );  // The output buffer pitch is 64 pixels times 32 bits per pixel
```

Address: 402B_4000h base + F0h offset = 402B_40F0h

36.8.17 PS Background Color (PXP_PSBACKGROUND)

PS Background Pixel Color. This register provides a pixel value used when processing pixels outside of the region specified by the PS Coordinate registers. This value can effectively be used to set the color of the letterboxing region around the PS image.

This register contains a pixel value to be used for any PS pixels that fall outside the PS extents. This is effectively a background or letterbox color. The CSC1 control and datapath pixel format should be considered when selecting the background color.

**EXAMPLE**
PXP_PS_BACKGROUND_WR(0x00000000); // letterbox is black
PXP_PS_BACKGROUND_WR(0x00800000); // letterbox is dark red
PXP_PS_BACKGROUND_WR(0x00008000); // letterbox is dark green
PXP_PS_BACKGROUND_WR(0x00000080); // letterbox is dark blue

Address: 402B_4000h base + 100h offset = 402B_4100h

</tr>
</tbody>
</table>

36.8.18 PS Scale Factor Register (PXP_PS_SCALE)

PS Scale Factor. This register provides the scale factor for the PS buffer.

The maximum down scaling factor is 1/2 such that the output image in either axis is 1/2 the size of the source. The maximum up scaling factor is 2^12 for either axis. The reciprocal of the scale factor should be loaded into this register. To reduce the PS buffer by a factor of two in the output frame buffer, a value of 0.0000_0000_0000 should be loaded into this register. To scale up by a factor of 4, the value of 0.0100_0000_0000, should be loaded into this register. To scale up by 8/5, the value of 0.1010_0000_0000 should be loaded.

EXAMPLE

PXP_PS_SCALE_WR(0x10001000); // 1:1 scaling (0x1.000)
PXP_PS_SCALE_WR(0x08000800); // 2x scaling (0x0.800)
PXP_PS_SCALE_WR(0x20002000); // 1/2x scaling (0x2.000)

</table>

**36.8.19 PS Scale Offset Register (PXP_PS_OFFSET)**

PS Scale Offset. This register provides the initial scale offset for the PS buffer.

---

i.MX RT1060 Processor Reference Manual, Rev. 2, 12/2019

1944

NXP Semiconductors
The X and Y offset provides the ability to access the source image with a per sub-pixel granularity. This provides the capability to use all source pixels to effect the output PS image. The fixed offset values can be used for sub-pixel adjustments in the bilinear scaling filter. For example, when scaling an image down by a factor of 2, an initial offset of 0x0 would result in sub-sampling every other pixel. If a fixed offset of 0x800 (1/2), all pixels are used in scaling the final output pixel value. In this case, the first output pixel would be the sum of (1/2*P0) + (1/2*P1). This fixed offset is applied after the decimation filter stage, and before the bilinear filter stage.

**EXAMPLE**

```
PXP_PS_SCALE_WR(0x2000_2000); // 1/2x scaling (0x2.000)
PXP_PS_OFFSET_WR(0x0800_0800); // half-pixel offset in both X and Y to ensure averaging versus pixel decimation
```

Address: 402B_4000h base + 120h offset = 402B_4120h

**36.8.20 PS Color Key Low (PXP_PS_CLRKEYLOW)**

This register contains the color key low value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP_PS_CLRKEYLOW and PXP_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP_PS_BACKGROUND color is passed down the pixel pipeline.

**EXAMPLE**
36.8.21 PS Color Key High (PXP_PS_CLRKEYHIGH)

This register contains the color key high value for the PS buffer.

When processing an image, if the PXP finds a pixel in the PS buffer with a color that falls in the range between PXP_PS_CLRKEYLOW and PXP_PS_CLRKEYHIGH, it will insert the pixel from the AS channel. If the current AS pixel is letterboxed or if the AS also matches its colorkey range, the PXP_PS_BACKGROUND color is passed down the pixel pipeline.

EXAMPLE

```
// colorkey values between
PXP_PS_CLRKEYLOW_WR (0x008000); // medium green and
PXP_PS_CLRKEYHIGH_WR(0x00FF00); // light green
```

Address: 402B_4000h base + 140h offset = 402B_4140h

### 36.8.23 Alpha Surface Buffer Pointer (PXP_AS_BUF)

Alpha Surface 0 Buffer Address Pointer. This register points to the beginning of the Alpha Surface 0 input buffer.

This register is used to indicate the base address of the AS buffer.

**EXAMPLE**

```c
u32* alpha_ptr;
PXP_ASn_WR(0,alpha_ptr);
```

Address: 402B_4000h base + 160h offset = 402B_4160h

### PXP_AS_BUF field descriptions

<table>

</tr>
</tbody>
</table>
36.8.24 Alpha Surface Pitch (PXP_AS_PITCH)

This register contains the alpha surface pitch in bytes.

Any byte value will indicate the vertical pitch. This value will be used in AS pixel address calculations. This value has no relation to the UL and LR registers. It specifies how many bytes are between two vertically adjacent pixels in the input AS surface.

**EXAMPLE**

```
PXP_AS_PITCH_WR( 1920 * 4 ); // The output buffer pitch is HD resolution at 32 bits per pixel
```

Address: 402B_4000h base + 170h offset = 402B_4170h

| Bit | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

</tbody>
</table>

36.8.25 Overlay Color Key Low (PXP_AS_CLRKEYLOW)

This register contains the color key low value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

**EXAMPLE**

```
PXP_AS_CLRKEYLOW_WR (0x000000); // black and
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red
```
Address: 402B_4000h base + 180h offset = 402B_4180h

| Bit | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 23  | 22  | 21  | 20  | 19  | 18  | 17  | 16  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| R   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| W   |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |     |
| Reset | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   | 0   |

**36.8.26 Overlay Color Key High (PXP_AS_CLRKEYHIGH)**

This register contains the color key high value for the AS buffer.

When processing an image, the if the PXP finds a pixel in the current overlay image with a color that falls in the range from the ASCOLORKEYLOW to ASCOLORKEYHIGH range, it will use the PS pixel value for that location. If no PS image is present or if the PS image also matches its colorkey range, the PS background color is used. Colorkey operations are higher priority than alpha or ROP operations.

**EXAMPLE**

```c
// colorkey values between
PXP_AS_CLRKEYLOW_WR (0x000000); // black and
PXP_AS_CLRKEYHIGH_WR(0x800000); // medium red
```

Address: 402B_4000h base + 190h offset = 402B_4190h

**PIXEL**

High range of RGB color key applied to AS buffer. Each overlay has an independent colorkey enable.
36.8.27  Color Space Conversion Coefficient Register 0
(PXP_CSC1_COEF0)

This register contains color space conversion coefficients in two's compliment notation.

The coefficient 0 register contains coefficients used in the color space conversion algorithm. The Y and UV offsets are added to the source buffer to normalize them before the conversion. C0 is the coefficient that is used to multiply the luma component of the data for all three RGB components.

EXAMPLE

```c
// The equations used for Colorspace conversion are:
//     R = C0*(Y+YOFFSET) + C1(V+UV_OFFSET)
//     G = C0*(Y+YOFFSET) + C3(U+UV_OFFSET) + C2(V+UV_OFFSET)
//     R = C0*(Y+YOFFSET) + C4(U+UV_OFFSET)

PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 402B_4000h base + 1A0h offset = 402B_41A0h

<td>Two's compliment Y multiplier coefficient. YUV=0x100 (1.000) YCbCr=0x12A (1.164)</td>
</tr>
<tr>
<td>17–9 UV_OFFSET</td>
<td>Two's compliment phase offset implicit for CbCr data. Generally used for YCbCr to RGB conversion. YCbCr=0x180, YUV=0x000 (typically -128 or 0x180 to indicate normalized -0.5 to 0.5 range)</td>
</tr>
<tr>
<td></td>
<td>Y_OFFSET Two's compliment amplitude offset implicit in the Y data. For YUV, this is typically 0 and for YCbCr, this is typically -16 (0x1F0)</td>
</tr>
</tbody>
</table>

### 36.8.28 Color Space Conversion Coefficient Register 1 (PXP_CSC1_COEF1)

This register contains color space conversion coefficients in two's compliment notation.

The Coefficient 1 register contains coefficients used in the color space conversion algorithm. C1 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the red component. C4 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the blue component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

**EXAMPLE**

```
PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```
36.8.29  Color Space Conversion Coefficient Register 2 (PXP_CSC1_COEF2)

This register contains color space conversion coefficients in two's compliment notation.

The Coefficient 2 register contains coefficients used in the color space conversion algorithm. C2 is the coefficient that is used to multiply the chroma (Cr/V) component of the data for the green component. C3 is the coefficient that is used to multiply the chroma (Cb/U) component of the data for the green component. Both values should be coded as a two's compliment fixed point number with 8 bits right of the decimal.

**EXAMPLE**

```c
// NOTE: The default values for the CSCCOEF2 register are incorrect. C2 should be 0x76B and C3 should be 0x79C for proper operation.

PXP_CSCCOEF0_WR(0x04030000); // YUV coefficients: C0, Yoffset, UVoffset
PXP_CSCCOEF1_WR(0x01230208); // YUV coefficients: C1, C4
PXP_CSCCOEF2_WR(0x076B079b); // YUV coefficients: C2, C3
```

Address: 402B_4000h base + 1C0h offset = 402B_41C0h

</tr>
</tbody>
</table>

### 36.8.31 Next Frame Pointer (PXP_NEXT)

This register contains a pointer to a data structure used to reload the PXP registers at the end of the current frame.

To enable this functionality, software must write this register while the PXP is processing the current data frame (if the PXP is currently idle, this will also initiate an immediate load of registers from the pointer). The process of writing this register (WRITE operation) will set a semaphore in hardware to notify the control logic that a register...
reload operation must be performed when the current frame processing is complete. At
the end of a frame, the PXP will fetch the register settings from this location, signal an
interrupt to software, then proceed with rendering the next frame of data. Software may
cancel the reload operation by issuing a CLEAR operation to this register. SET and
TOGGLE operations should not be used when addressing this register. All registers will
be reloaded with the exception of the following: STAT, CSCCOEFn, NEXT. All other
registers will be loaded in the order they appear in the register map. After the pointer's
contents have been loaded into the PXP's registers, the NEXT_IRQ interrupt will be
issued (see the PXP_STATUS register).

EXAMPLE

```c
// create register command structure in memory
u32* pxp_commands0[48], pxp_commands1;
    u32 rc;

    // initialize control structure for frame 0
    pxp_commands0[0] = ...; // CTRL
    pxp_commands0[1] = ...; // OUT Buffer
    ...
    pxp_commands0[47] = ..; // Overlay7 param2
   
    // initialize control structure for frame 1
    pxp_commands1[0] = ...; // CTRL
    pxp_commands1[1] = ...; // OUT Buffer
    ...
    pxp_commands1[47] = ..; // Overlay7 param2

    // poll until a command isn't queued
    while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED);
    PXP_NEXT_WR(pxp_commands0); // enable PXP operation 0 via command pointer

    // poll until first command clears
    while (rc=PXP_NEXT_RD() & BM_PXP_NEXT_ENABLED);
    PXP_NEXT_WR(pxp_commands1); // enable PXP operation 1 via command pointer
```

Address: 402B_4000h base + 400h offset = 402B_4400h
### PXP_NEXT field descriptions

Chapter 37
Audio Overview

37.1 Audio Overview

The audio subsystem consists of the following modules: SAI-1, SAI-2, SAI-3, SPDIF and MQS. In addition, the IOMUX must be appropriately configured to get signals in and out of the chip.

Audio Module Overview provides an overview of each of the audio modules, followed by a module-specific section.

37.1.1 Audio Module Overview

The following figure shows a high level block diagram of the audio subsystem.
SAIn are synchronous serial interfaces used to transfer audio data. They can be accessed by both the eDMA and ARM CPUs. Their input/output are connected to the pads through IOMUX.

MQS (medium quality speaker) is used to convert the I2S audio data from SAI to PWM signals that can drive external speaker directly. Its audio source comes from SAI-3 and its output is connected to pads through IOMUX.

The Sony/Philips digital interface (SPDIF) audio module is a stereo transceiver that allows the processor to receive and transmit digital audio over it. The SPDIF receiver section includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency. A recovered clock is provided by the SPDIF receiver section and may be used to drive both internal and external components in the system.

The audio interfaces are summarized as the table below.

**Table 37-1. Audio Interface Summary**

<table>

</tr>
</tbody>
</table>

SAI-1 is used for multi-channel audio interface, which supports up to 8-channels audio input or 8-channels audio output at 384 kHz/32-bit. SAI-2, SAI-3 can be used for stereo audio input and output up to 384 kHz/32-bit. Also SAI-3 is able to drive MQS directly as a low-cost audio output.

To reduce IO count and keep the flexibilities of supporting multiple RX and TX data lines application, SAI-1 has following options on data pin multiplexing.

Table 37-2. SAI-1 TX/RX Data Multiplexing

SAI-1 to IOMUXC connection is implemented as shown in the diagram below.

Figure 37-2. SAI-1 TX/RX Data Multiplexing

Detailed clock multiplexing scheme is shown in the following figure.
### 37.1.2 Medium Quality Sound (MQS)

MQS is used to generate medium quality audio via a standard GPIO in the pinmux. The user can connect stereo speakers or headphones to a power amplifier without an additional DAC chip.

- 2-channel, LSB-valid 16 bit, MSB shift-out first serial data (sdata)
- Frame sync aligned with the left channel data
- 44 kHz or 48 kHz I2S signals from SAI3
• SNR target as no more than 20 dB for the signals below 10 kHz
• Signals over 10 kHz have worse THD+N values

### 37.1.3 Synchronous Audio Interface (SAI)

- Transmitter with independent Bit Clock and Frame Sync supporting 1 data line
- Receiver with independent Bit Clock and Frame Sync supporting 1 data line
- Maximum Frame Size of 32 Words
- Word size programmable from 8-bits to 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous FIFO for each Transmit and Receive data line
- Graceful restart after FIFO Error

### 37.1.4 Sony/Philips Digital Interface (SPDIF)

The Sony/Philips Digital Interface (SPDIF) module is a stereo transceiver that allows the processor to receive and transmit digital audio over it using the IEC60958 standard, consumer format. The chip provides a single SPDIF receiver with one input, and one SPDIF transmitter with one output.

The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and features a frequency measurement block that allows the precise measurement of the incoming sampling frequency.

The clock recovered by the SPDIF receiver is provided to drive both internal and external components in the system such as the SPDIF transmitter, ESAI ports, as well as external A/Ds or D/As, with clocking control provided via related registers.

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter. The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in two 16-word-deep FIFOs, one FIFO for the left channel, the other FIFO for the right channel. The FIFOs support programmable watermark levels so that FIFO Full service request can be triggered when the combined number of data words stored in both FIFOs is 2, 8, 16 or 32 words. It is recommended to program the watermark level to trigger a FIFO Full service request when 16 word locations are filled. For optimal performance when servicing the FIFO Full service request, the FIFOs should be read alternately, starting with the left channel FIFO. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.
For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers, and the data is stored in two 16-word-deep FIFOs, one for the right channel, the other for the left channel. The FIFOs support programmable watermark levels so that FIFO Empty service request can be triggered when the combined number of empty data words locations in both FIFOs is 8, 16, 24 or 32 words. It is recommended to program the watermark level to trigger a FIFO Empty service request when 16 word locations are empty. For optimal performance when servicing the FIFO Empty service request, the FIFOs should be written alternately, starting with the left channel FIFO. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates an SPDIF output bitstream in the biphase mark format (IEC 60958), which consists of audio data, channel status and user bits.

The data handled by the SPDIF module is 24-bit wide. The 24-bit SPDIF data is aligned in the 24 least significant bits of the 32-bit shared peripheral bus data word. The 8 most significant bits of the 32-bit word are ignored by the SPDIF Transmitter when data is being stored in the Transmit FIFOs from the peripheral bus. The 8 most significant bits of the 32-bit word are zeroed by the SPDIF Receiver module when the data is being read from the Receiver FIFOs to the peripheral bus.

Note that 16-bit data is left-aligned in the 24-bit word format of the SPDIF. This means that when receiving 16-bit data, it will be located in the middle two bytes of the 32-bit peripheral bus data word, while the 8 bits of the MSB and the 8 bits of the LSB will be zero. When 16-bit data is to be transmitted, the 32-bit word to be written to the SPDIF Transmit FIFOs should be created as follows: the 16-bit data should be located in the middle two bytes of the 32-bit data word and the 8 bits of the LSB must be set to zero, while the 8 bits of the MSB will be ignored.

The SPDIF Transmit clock is generated by the SPDIF internal clock generator module and the clock sources are from outside of the SPDIF block. The clock sources should provide a clock that is at least 64 x Fs, where Fs is the sampling frequency. The external clock source should provide at least 128 x Fs. Clocks of higher frequency may be provided as long as the multiplication factor is a power of 2 (for example, 128x, 256x or 512x). Also, clock frequency precision of 100ppm or better should be provided.

**NOTE**
Number of TX and RX data lines for SAI1 and SAI2/SAI3 are 4, and 1 respectively.

**NOTE**
In this device, it does NOT support synchronous mode between different SAI peripherals.

For more details about the features and clocking of different SAI instances, see the Audio Subsystem Overview section.
38.2 Introduction

The I²S (or I2S) module provides a synchronous audio interface (SAI) that supports full-duplex serial interfaces with frame synchronization such as I²S, AC97, TDM, and codec/DSP interfaces.

38.2.1 Features

Note that some of the features are not supported across all SAI instances; see the chip-specific information in the first section of this chapter.

- Transmitter with independent bit clock and frame sync supporting 4 data lines
- Receiver with independent bit clock and frame sync supporting 4 data lines
- Each data line can support a maximum Frame size of 32 words
- Word size of between 8-bits and 32-bits
- Word size configured separately for first word and remaining words in frame
- Asynchronous 32 x 32-bit FIFO for each transmit and receive data line
- Supports graceful restart after FIFO error
- Supports automatic restart after FIFO error without software intervention
- Supports packing of 8-bit and 16-bit data into each 32-bit FIFO word
- Supports combining multiple data line FIFOs into single data line FIFO

38.2.2 Block diagram

The following block diagram also shows the module clocks.
38.2.3 Modes of operation

Module power modes include Run mode, Stop modes, and Debug mode.

38.2.3.1 Run mode

In Run mode, the SAI transmitter and receiver operate normally.
### 38.2.3.2 Stop modes

In Stop mode, the SAI transmitter and/or receiver can continue operating provided the appropriate Stop Enable bit is set (TCSR[STOPE] and/or RCSR[STOPE], respectively), and provided the transmitter and/or receiver is/are using an externally generated bit clock or an Audio Master Clock that remains operating in Stop mode. The SAI transmitter and/or receiver can generate an asynchronous interrupt to wake the CPU from Stop mode.

In Stop mode, if the Transmitter Stop Enable (TCSR[STOPE]) bit is clear, the transmitter is disabled after completing the current transmit frame, and, if the Receiver Stop Enable (RCSR[STOPE]) bit is clear, the receiver is disabled after completing the current receive frame. Entry into Stop mode is prevented (not acknowledged) while waiting for the transmitter and receiver to be disabled at the end of the current frame.

### 38.2.3.3 Debug mode

In Debug mode, the SAI transmitter and/or receiver can continue operating provided the Debug Enable bit is set. When TCSR[DBGE] or RCSR[DBGE] bit is clear and Debug mode is entered, the SAI is disabled after completing the current transmit or receive frame. The transmitter and receiver bit clocks are not affected by Debug mode.

### 38.3 External signals

*Table continues on the next page...*
38.4 Functional description

This section provides a complete functional description of the block.

38.4.1 SAI clocking

The SAI clocks include:

- The audio master clock
- The bit clock
- The bus clock

38.4.1.1 Audio master clock

The audio master clock is used to generate the bit clock when the receiver or transmitter is configured for an internally generated bit clock. The transmitter and receiver can independently select between the bus clock and up to three audio master clocks to generate the bit clock.

The audio master clock generation and selection is chip-specific. Refer to chip-specific clocking information about how the audio master clocks are generated.

38.4.1.2 Bit clock

The SAI transmitter and receiver support asynchronous free-running bit clocks that can be generated internally from an audio master clock or supplied externally. There is also the option for synchronous bit clock and frame sync operation between the receiver and transmitter or between multiple SAI peripherals.

- If both transmitter and receiver are configured for asynchronous operation, then the transmitter and receiver will each use their own bit clock and frame sync.
• If the *transmitter* is configured for asynchronous mode and the receiver is configured for synchronous mode, then both transmitter and receiver will use the *transmitter* bit clock and frame sync.

• If the *receiver* is configured for asynchronous mode and the transmitter is configured for synchronous mode, then both transmitter and receiver will use the *receiver* bit clock and frame sync.

Note that the software configures synchronous or asynchronous mode, and that choice selects the bit clock/frame sync used.

Externally generated bit clocks must be:

• Enabled before the SAI transmitter or receiver is enabled
• Disabled after the SAI transmitter or receiver is disabled and completes its current frames

If the SAI transmitter or receiver is using an externally generated bit clock in asynchronous mode and that bit clock is generated by an SAI that is disabled in stop mode, then the transmitter or receiver should be disabled by software before entering stop mode. This issue does not apply when the transmitter or receiver is in a synchronous mode because all synchronous SAIs are enabled and disabled simultaneously.

### 38.4.1.3 Bus clock

The bus clock is used by the control and configuration registers and to generate synchronous interrupts and DMA requests.

**NOTE**

Although there is no specific minimum bus clock frequency specified, the bus clock frequency must be fast enough (relative to the bit clock frequency) to ensure that the FIFOs can be serviced, without generating either a transmitter FIFO underrun or receiver FIFO overflow condition.

### 38.4.2 SAI resets

The SAI is asynchronously reset on system reset. The SAI has a software reset and a FIFO reset.
38.4.2.1 Software reset

The SAI transmitter includes a software reset that resets all transmitter internal logic, including the bit clock generation, status flags, and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

The SAI receiver includes a software reset that resets all receiver internal logic, including the bit clock generation, status flags and FIFO pointers. It does not reset the configuration registers. The software reset remains asserted until cleared by software.

38.4.2.2 FIFO reset

The SAI transmitter includes a FIFO reset that synchronizes the FIFO write pointer to the same value as the FIFO read pointer. This empties the FIFO contents and is to be used after TCSR[FEF] is set, and before the FIFO is re-initialized and TCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI transmitter can also reset the FIFO of individual data channels by setting the appropriate TCR3[CFR] bit. This should only be done when the corresponding TCR3[TCE] bit is clear.

The SAI receiver includes a FIFO reset that synchronizes the FIFO read pointer to the same value as the FIFO write pointer. This empties the FIFO contents and is to be used after the RCSR[FEF] is set and any remaining data has been read from the FIFO, and before the RCSR[FEF] is cleared. The FIFO reset is asserted for one cycle only.

The SAI receiver can also reset the FIFO of individual data channels by setting the appropriate RCR3[CFR] bit. This should only be done when the corresponding RCR3[RCE] bit is clear.

38.4.3 Synchronous modes

The SAI transmitter and receiver can operate synchronously to each other.

38.4.3.1 Synchronous mode

The SAI transmitter and receiver can be configured to operate with synchronous bit clock and frame sync.

If the transmitter bit clock and frame sync are to be used by both the transmitter and receiver:
• The transmitter must be configured for asynchronous operation and the receiver for synchronous operation.
• In synchronous mode, the receiver is enabled only when both the transmitter and receiver are enabled.
• It is recommended that the transmitter is the last enabled and the first disabled.

If the receiver bit clock and frame sync are to be used by both the transmitter and receiver:

• The receiver must be configured for asynchronous operation and the transmitter for synchronous operation.
• In synchronous mode, the transmitter is enabled only when both the receiver and transmitter are both enabled.
• It is recommended that the receiver is the last enabled and the first disabled.

When operating in synchronous mode, only the bit clock, frame sync, and transmitter/receiver enable are shared. The transmitter and receiver otherwise operate independently, although configuration registers must be configured consistently across both the transmitter and receiver.

### 38.4.4 Frame sync configuration

When enabled, the SAI continuously transmits and/or receives frames of data. Each frame consists of a fixed number of words and each word consists of a fixed number of bits. Within each frame, any given word can be masked causing the receiver to ignore that word and the transmitter to tri-state for the duration of that word.

The frame sync signal is used to indicate the start of each frame. A valid frame sync requires a rising edge (if active high) or falling edge (if active low) to be detected and the transmitter or receiver cannot be busy with a previous frame. A valid frame sync is also ignored (slave mode) or not generated (master mode) for the first four bit clock cycles after enabling the transmitter or receiver.

The transmitter and receiver frame sync can be configured independently with any of the following options:

• Externally generated or internally generated
• Active high or active low
• Assert with the first bit in frame or asserts one bit early
• Assert for a duration between 1 bit clock and the first word length
• Frame length from 1 to 32 words per frame
• Word length to support 8 to 32 bits per word
• First word length and remaining word lengths can be configured separately
• Words can be configured to transmit/receive MSB first or LSB first

These configuration options cannot be changed after the SAI transmitter or receiver is enabled.

38.4.5 Data FIFO

Each transmit and receive channel includes a FIFO of size 32 x 32-bit. The FIFO data is accessed using the SAI Transmit/Receive Data Registers.

38.4.5.1 Data alignment

Data in the FIFO can be aligned anywhere within the 32-bit wide register through the use of the First Bit Shifted configuration field, which selects the bit index (between 31 and 0) of the first bit shifted.

Examples of supported data alignment and the required First Bit Shifted configuration are illustrated in Figure 38-2 for LSB First configurations and Figure 38-3 for MSB First configurations.

![Table: How data is written to the FIFO, using First Bit Shifted field (FBT)](image)

Figure 38-3. SAI first bit shifted, MSB first

### 38.4.5.2 FIFO pointers

When writing to a Transmit Data Register (TDR\(n\)), the Write FIFO Pointer (WFP) of the corresponding Transmit FIFO Register (TFR\(n\)) increments after each valid write. The SAI supports 8-bit, 16-bit and 32-bit writes to the Transmit Data Register and the FIFO pointer will increment after each individual write. Note that 8-bit writes should only be used when transmitting up to 8-bit data; 16-bit writes should only be used when transmitting up to 16-bit data.

- If the Transmit FIFO is full, then writes to a Transmit Data Register are ignored.
- If the Transmit FIFO is empty, then to avoid a FIFO underrun, the Transmit Data Register must be written at least 3 bit clocks before the start of the next unmasked word. Before enabling the transmitter, the Transmit FIFO should be initialized with data (since after the transmitter is enabled, the transmitter will start a new frame, and if no data is in the FIFO, then the transmitter will immediately give an error).

When reading a Receive Data Register (RDR\(n\)), the Read FIFO Pointer (RFP) of the corresponding Receive FIFO Register (RFR\(n\)) increments after each valid read. The SAI supports 8-bit, 16-bit and 32-bit reads from the RDR and the FIFO pointer will increment after each individual read. Note that 8-bit reads should only be used when receiving up to 8-bit data; 16-bit reads should only be used when receiving up to 16-bit data.
• If the Receive FIFO is empty, then reads from a Receive Data Register are ignored.
• If the Receive FIFO is full, then to avoid a FIFO overrun, the Receive Data Register must be read at least 3 bit clocks before the end of an unmasked word.

38.4.5.3 FIFO packing

FIFO packing supports storing multiple 8-bit or 16-bit data words in one 32-bit FIFO word for the transmitter and/or receiver. While this can be emulated by adjusting the number of bits per word and number of words per frame (for example, one 32-bit word per frame versus two 16-bit words per frame), FIFO packing does not require even multiples of words per frame and fully supports word masking. When FIFO packing is enabled, the FIFO pointers only increment when the full 32-bit FIFO word has been written (transmit) or read (receive) by software, supporting scenarios where different words within each frame are loaded/stored in different areas of memory.

When 16-bit FIFO packing is enabled for transmit, the transmit shift register is loaded at the start of each frame and after every second unmasked transmit word. The first word transmitted is taken from 16-bit word at byte offset $0$ (first bit is selected by TCFG5[FBT] must be configured within this 16-bit word) and the second word transmitted is taken from the 16-bit word at byte offset $2$ (first bit is selected by TCSR5[FBT][3:0]). The transmitter will transmit logic zero until the start of the next word once the 16-bit word has been transmitted.

When 16-bit FIFO packing is enabled for receive, the receive shift register is stored after every second unmasked received word, and at the end of each frame if there is an odd number of unmasked received words in each frame. The first word received is stored in the 16-bit word at byte offset $0$ (first bit is selected by RCFG5[FBT] and must be configured within this 16-bit word) and the second word received is stored in the 16-bit word at byte offset $2$ (first bit is selected by RCSR5[FBT][3:0]). The receiver will ignore received data until the start of the next word once the 16-bit word has been received.

The 8-bit FIFO packing is similar to 16-bit packing except four words are loaded or stored into each 32-bit FIFO word. The first word is loaded/stored in byte offset $0$, second word in byte offset $1$, third word in byte offset $2$ and fourth word in byte offset $3$. The TCFG5[FBT] and/or RCFG5[FBT] must be configured within byte offset $0$. 
38.4.5.4 FIFO Combine

FIFO combining mode allows the separate FIFOs for multiple data channels to be used as a single FIFO for either software accesses or a single data channel or both. Note that the enabled data channels must be contiguous and data channel 0 must be enabled when FIFO Combine mode is enabled.

Combining FIFOs for software access (writing transmit FIFO registers, reading receive FIFO registers) allows a DMA controller or software to read or write multiple FIFOs without incrementing the address that is accessed. Once enabled, the first software access to a FIFO register will access the first enabled channel FIFO, while the second access to a FIFO register will access the second enabled channel FIFO. This continues until software accesses the last enabled channel FIFO and the pointer resets back to the first enabled channel FIFO. To reset the pointer manually, software can reset the FIFOs or disable the FIFO combining on software accesses.

Combining FIFOs for transmit data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with identical data output on each enabled data channel. The transmit shift registers for all enabled data channels are loaded at the start of each frame and every N unmasked words (where N is the number of enabled data channels). The first word transmitted is loaded from the first enabled channel FIFO, while the second word transmitted is loaded from the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always loaded from the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Combining FIFOs for receive data channels allows one data channel to use the FIFOs of all enabled channel FIFOs, with received data from channel 0 stored into each enabled data channel. The receive shift register for all enabled data channels are stored after every N unmasked words (where N is the number of enabled data channels). The first word received is stored to the first enabled channel FIFO, while the second word received is stored to the second enabled channel FIFO, and so on until the end of the frame. Since the first word in each frame is always stored the first enabled data channel, it is recommended that the number of unmasked words in each frame is evenly divisible by the number of enabled data channels.

Note that combining FIFOs for data channels will load or store each channel FIFO at the same time. This means that FIFO error conditions are only checked every N words (where N is the number of enabled data channels) and that the FIFO warning and request flags will assert if any of the enabled data channel meets the warning flag or request flag conditions.
38.4.6  Word mask register

The SAI transmitter and receiver each contain a word mask register, namely TMR and RMR, that can be used to mask any word in the frame. Because the word mask register is double buffered, software can update it before the end of each frame to mask a particular word in the next frame.

The TMR causes the Transmit Data pin to be tri-stated for the length of each selected word and the transmit FIFO is not read for masked words.

The RMR causes the received data for each selected word to be discarded and not written to the receive FIFO.

38.4.7  Interrupts and DMA requests

The SAI transmitter and receiver generate separate interrupts and separate DMA requests, but support the same status flags. Asynchronous versions of the transmitter and receiver interrupts are generated to wake up the CPU from stop mode.

38.4.7.1  FIFO request flag

The FIFO request flag is set based on the number of entries in the FIFO and the FIFO watermark configuration.

The transmit FIFO request flag is set when the number of entries in any of the enabled transmit FIFOs is less than or equal to the transmit FIFO watermark configuration and is cleared when the number of entries in each enabled transmit FIFO is greater than the transmit FIFO watermark configuration.

The receive FIFO request flag is set when the number of entries in any of the enabled receive FIFOs is greater than the receive FIFO watermark configuration and is cleared when the number of entries in each enabled receive FIFO is less than or equal to the receive FIFO watermark configuration.

The FIFO request flag can generate an interrupt or a DMA request.

38.4.7.2  FIFO warning flag

The FIFO warning flag is set based on the number of entries in the FIFO.
The transmit warning flag is set when the number of entries in any of the enabled transmit FIFOs is empty and is cleared when the number of entries in each enabled transmit FIFO is not empty.

The receive warning flag is set when the number of entries in any of the enabled receive FIFOs is full and is cleared when the number of entries in each enabled receive FIFO is not full.

The FIFO warning flag can generate an Interrupt or a DMA request.

### 38.4.7.3 FIFO error flag

The transmit FIFO error flag is set when any of the enabled transmit FIFOs underflow. After it is set, all enabled transmit channels will transmit zero data before TCSR[FEF] is cleared.

When TCR4[FCONT] is set, the FIFO will continue transmitting data following an underflow without software intervention. To ensure that data is transmitted in the correct order, the transmitter will continue from the same word number in the frame that caused the FIFO to underflow, but only after new data has been written to the transmit FIFO. Software should still clear the TCSR[FEF] flag, but without reinitializing the transmit FIFOs.

RCSR[FEF] is set when any of the enabled receive FIFOs overflow. After it is set, all enabled receive channels discard received data until RCSR[FEF] is cleared and the next receive frame starts. All enabled receive FIFOs should be emptied before RCSR[FEF] is cleared.

When RCR4[FCONT] is set, the FIFO will continue receiving data following an overflow without software intervention. To ensure that data is received in the correct order, the receiver will continue from the same word number in the frame that caused the FIFO to overflow, but only after data has been read from the receive FIFO. Software should still clear the RCSR[FEF] flag, but without emptying the receive FIFOs.

The FIFO error flag can generate only an interrupt.

### 38.4.7.4 Sync error flag

The sync error flag, TCSR[SEF] or RCSR[SEF], is set when configured for an externally generated frame sync and the external frame sync asserts when the transmitter or receiver is busy with the previous frame. The external frame sync assertion is ignored and the sync error flag is set. When the sync error flag is set, the transmitter or receiver continues checking for frame sync assertion when idle or at the end of each frame.
The sync error flag can generate an interrupt only.

### 38.4.7.5 Word start flag

The word start flag is set at the start of the second bit clock for the selected word, as configured by the Word Flag register field.

The word start flag can generate an interrupt only.

### 38.5 Memory map and register definition

A read or write access to an address from offset 0x100 and above will result in a bus error.

### 38.5.1 I2S register descriptions

### 38.5.1.4.3 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 31    | Transmitter Enable  
Enables/disables the transmitter. When software clears this field, the transmitter remains enabled, and this bit remains set, until the end of the current frame.  
0b - Transmitter is disabled.  
1b - Transmitter is enabled, or transmitter has been disabled and has not yet reached end of frame. |
| 30    | Stop Enable  
Configures transmitter operation in Stop mode.  
0b - Transmitter disabled in Stop mode.  
1b - Transmitter enabled in Stop mode. |
| 29    | Debug Enable  
Enables/disables transmitter operation in Debug mode. The transmit bit clock is not affected by debug mode.  
0b - Transmitter is disabled in Debug mode, after completing the current frame.  
1b - Transmitter is enabled in Debug mode. |
| 28    | Bit Clock Enable  
Enables the transmit bit clock, separately from the TE. This field is automatically set whenever TE is set. When software clears this field, the transmit bit clock remains enabled, and this bit remains set, until the end of the current frame.  
0b - Transmit bit clock is disabled.  
1b - Transmit bit clock is enabled. |
| 27-26 | Reserved |
| 25    | FIFO Reset  
Empties the FIFO, and sets the FIFO read and write pointers to the same value, which may or may not be zero. Reading this field will always return zero. FIFO pointers should only be reset when the transmitter is disabled or the FIFO error flag is set.  
0b - No effect.  
1b - FIFO reset. |
| 24    | Software Reset |

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| SR    | When set, resets the internal transmitter logic including the FIFO read and write pointers. Software-visible registers are not affected, except for the status registers.  
  - 0b - No effect.  
  - 1b - Software reset. |
| 23-21 | Reserved |
| 20    | Word Start Flag  
  - Indicates that the start of the configured word has been detected. Write a logic 1 to this field to clear this flag.  
  - 0b - Start of word not detected.  
  - 1b - Start of word detected. |
| 19    | Sync Error Flag  
  - Indicates that an error in the externally-generated frame sync has been detected. Write a logic 1 to this field to clear this flag.  
  - 0b - Sync error not detected.  
  - 1b - Frame sync error detected. |
| 18    | FIFO Error Flag  
  - Indicates that an enabled transmit FIFO has underrun. Write a logic 1 to this field to clear this flag.  
  - 0b - Transmit underrun not detected.  
  - 1b - Transmit underrun detected. |
| 17    | FIFO Warning Flag  
  - Indicates that an enabled transmit FIFO is empty.  
  - 0b - No enabled transmit FIFO is empty.  
  - 1b - Enabled transmit FIFO is empty. |
| 16    | FIFO Request Flag  
  - Indicates that the number of words in an enabled transmit channel FIFO is less than or equal to the transmit FIFO watermark.  
  - 0b - Transmit FIFO watermark has not been reached.  
  - 1b - Transmit FIFO watermark has been reached. |
| 15-13 | Reserved |
| 12    | Word Start Interrupt Enable  
  - Enables/disables word start interrupts.  
  - 0b - Disables interrupt.  
  - 1b - Enables interrupt. |
| 11    | Sync Error Interrupt Enable  
  - Enables/disables sync error interrupts.  
  - 0b - Disables interrupt.  
  - 1b - Enables interrupt. |
| 10    | FIFO Error Interrupt Enable  
  - Enables/disables FIFO error interrupts.  
  - 0b - Disables the interrupt.  
  - 1b - Enables the interrupt. |
| 9     | FIFO Warning Interrupt Enable  
  - Enables/disables FIFO warning interrupts.  
  - 0b - Disables the interrupt.  
  - 1b - Enables the interrupt. |

<td>Synchronous Mode</td>
</tr>
</tbody>
</table>

Table continues on the next page...
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| SYNC  | Configures between asynchronous and synchronous modes of operation. When configured for a synchronous mode of operation, the receiver must be configured for asynchronous operation.  
  0b - Asynchronous mode.  
  1b - Synchronous with receiver. |
| 29    | Bit Clock Swap  
  This field swaps the bit clock used by the transmitter. When the transmitter is configured in asynchronous mode and this bit is set, the transmitter is clocked by the receiver bit clock (RX_BCLK). This allows the transmitter and receiver to share the same bit clock, but the transmitter continues to use the transmit frame sync (TX_SYNC).  
  When the transmitter is configured in synchronous mode, the transmitter BCS field and receiver BCS field must be set to the same value. When both are set, the transmitter and receiver are both clocked by the transmitter bit clock (TX_BCLK) but use the receiver frame sync (RX_SYNC).  
  0b - Use the normal bit clock source.  
  1b - Swap the bit clock source. |
| 28    | Bit Clock Input  
  When this field is set and using an internally generated bit clock in either synchronous or asynchronous mode, the bit clock actually used by the transmitter is delayed by the pad output delay (the transmitter is clocked by the pad input as if the clock was externally generated). This has the effect of decreasing the data input setup time, but increasing the data output valid time.  
  The slave mode timing from the datasheet should be used for the transmitter when this bit is set. In synchronous mode, this bit allows the transmitter to use the slave mode timing from the datasheet, while the receiver uses the master mode timing. This field has no effect when configured for an externally generated bit clock.  
  0b - No effect.  
  1b - Internal logic is clocked as if bit clock was externally generated. |
| 27-26 | MCLK Select  
  Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.  
  **NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the meaning of each option.  
  00b - Bus Clock selected.  
  01b - Master Clock (MCLK) 1 option selected.  
  10b - Master Clock (MCLK) 2 option selected.  
  11b - Master Clock (MCLK) 3 option selected. |
| 25    | Bit Clock Polarity  
  Configures the polarity of the bit clock.  
  0b - Bit clock is active high with drive outputs on rising edge and sample inputs on falling edge.  
  1b - Bit clock is active low with drive outputs on falling edge and sample inputs on rising edge. |
| 24    | Bit Clock Direction  
  Configures the direction of the bit clock.  
  0b - Bit clock is generated externally in Slave mode.  
  1b - Bit clock is generated internally in Master mode. |
| 23-8  | Reserved |
| 7-0   | Bit Clock Divide  
  Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is \((\text{DIV} + 1) \times 2\). |

38.5.1.7.3 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>Reserved</td>
</tr>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>27-24</td>
<td>Channel FIFO Reset</td>
</tr>
<tr>
<td>CFR</td>
<td></td>
</tr>
</tbody>
</table>

Resets the FIFO pointers for a specific channel. Reading this field will always return zero. FIFO pointers should only be reset when a channel is disabled or the FIFO error flag is set.

The width of CFR field = the number of transmit channels (call it N). For example, if CFR is 2 bits wide, then bit position 24 refers to transmit channel 1 FIFO pointer and bit position 25 refers to transmit channel 2 FIFO pointer. Setting bit 24 resets transmit channel 1 FIFO pointer, and setting bit 25 enables transmit channel 2 FIFO pointer. Setting bit N will reset transmit channel N FIFO pointer.

0b - No effect.
1b - Transmit data channel N FIFO is reset.

NOTE: This field is not supported in every instance. The following table includes only supported registers.

### 38.5.1.12 SAI Transmit Mask Register (TMR)

#### 38.5.1.12.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>TMR</td>
<td>60h</td>
</tr>
</tbody>
</table>

#### 38.5.1.12.2 Function

This register is double-buffered and updates:

1. When TCSR[TE] is first set
2. At the end of each frame.

This allows the masked words in each frame to change from frame to frame.

#### 38.5.1.12.3 Diagram

</tr>
<tr>
<td></td>
<td>1b - Internal logic is clocked as if bit clock was externally generated.</td>
</tr>
<tr>
<td>27-26</td>
<td>MCLK Select</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
### Field | Function
--- | ---
Selects the audio Master Clock option used to generate an internally generated bit clock. This field has no effect when configured for an externally generated bit clock.

**NOTE:** Depending on the device, some Master Clock options might not be available. See the chip-specific information for the availability and chip-specific meaning of each option.

00b - Bus Clock selected.
01b - Master Clock (MCLK) 1 option selected.
10b - Master Clock (MCLK) 2 option selected.
11b - Master Clock (MCLK) 3 option selected.

25 | Bit Clock Polarity
--- | ---
Configures the polarity of the bit clock.

0b - Bit Clock is active high with drive outputs on rising edge and sample inputs on falling edge.
1b - Bit Clock is active low with drive outputs on falling edge and sample inputs on rising edge.

24 | Bit Clock Direction
--- | ---
Configures the direction of the bit clock.

0b - Bit clock is generated externally in Slave mode.
1b - Bit clock is generated internally in Master mode.

7-0 | Bit Clock Divide
--- | ---
Divides down the audio master clock to generate the bit clock when configured for an internal bit clock. The division value is \( (DIV + 1) \times 2 \).

</tbody>
</table>

*Table continues on the next page...*
### Field Function

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| FCONT  | Configures when the SAI will continue receiving after a FIFO error has been detected.  
|        | 0b - On FIFO error, the SAI will continue from the start of the next frame after the FIFO error flag has been cleared.  
|        | 1b - On FIFO error, the SAI will continue from the same word that caused the FIFO error to set after the FIFO warning flag has been cleared. |
| 27-26  | FIFO Combine Mode                                                         |
|        | When FIFO combine mode is enabled for FIFO reads, software reading any FIFO data register will alternate the read among the enabled data channel FIFOs. For example, if two data channels are enabled then the first read will be performed to the first enabled data channel FIFO and the second read will be performed to the second enabled data channel FIFO. Resetting the FIFO or disabling FIFO combine mode for FIFO reads will reset the pointer back to the first enabled data channel.  
|        | When FIFO combine mode is enabled for FIFO writes from the receive shift registers, the first enabled data channel input will alternate between the enabled data channel FIFOs. For example, if two data channels are enabled then the first unmasked received word will be stored in the first enabled data channel FIFO and the second unmasked received word will be stored in the second enabled data channel FIFO. Since the first word of the frame is always stored in the first enabled data channel FIFO, it is recommended that the number of unmasked words per frame is evenly divisible by the number of enabled data channels. |
| NOTE:  | This field is not supported in every instance. The following table includes only supported registers. |

### Field supported in | Field not supported in
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>

00b - FIFO combine mode disabled.  
01b - FIFO combine mode enabled on FIFO writes (from receive shift registers).  
10b - FIFO combine mode enabled on FIFO reads (by software).  
11b - FIFO combine mode enabled on FIFO writes (from receive shift registers) and reads (by software).  

<table>
<thead>
<tr>
<th>25-24</th>
<th>FIFO Packing Mode</th>
</tr>
</thead>
</table>
| FPACK | Enables packing of 8-bit data or 16-bit data into each 32-bit FIFO word. If the word size is greater than 8-bit or 16-bit then only the first 8-bit or 16-bits are stored to the FIFO. The first word in each frame always starts with a new 32-bit FIFO word and the first bit shifted must be configured within the first packed word. When FIFO packing is enabled, the FIFO read pointer will only increment when the full 32-bit FIFO word has been read by software.  
|       | 00b - FIFO packing is disabled  
|       | 01b - Reserved.  
|       | 10b - 8-bit FIFO packing is enabled  
|       | 11b - 16-bit FIFO packing is enabled |
| 23-21 | Reserved |
| 20-16 | Frame Size    |
| FRSZ  | Configures the number of words in each frame. The value written must be one less than the number of words in the frame. For example, write 0 for one word per frame. The maximum supported frame size is 32 words. |
| 15-13 | Reserved |

39.2 Overview

Medium quality sound (MQS) is used to generate medium quality audio via a standard GPIO in the pinmux, allowing the user to connect stereo speakers or headphones to a power amplifier without an additional DAC chip.

MQS accepts the following inputs:

- 2-channel, LSB-valid 16-bit, MSB shift-out first serial data (sdata)
- Frame sync asserting with the first bit of the frame (fs)
- Bit clock used to shift data out on the positive clock edge (bclk)

The 44 kHz or 48 kHz input signals from SAI3 are in left_justified format. MQS provides the SNR target as no more than 20 dB for the signals below 10 kHz. The signals above 10 kHz will have worse THD+N values.
MQS provides only simple audio reproduction. No internal pop, click or distortion artifact reduction methods are provided.

### 39.2.1 Block Diagram

**Figure 39-1. Block Diagram**

MQS has the following sub-modules:

1. **Channel Split**: Splits the I2S signals into separate left channel and right channel audio data.
2. **Noise Shaping**: Uses the sigma-delta algorithm to generate low-resolution, very high sampling audio, while the audio sampling rate is increased.
3. **PWM generation**: Generates the bit stream to the GPIO, which is then used to drive the amplifier and then to drive the external speakers or headphones.
4. **mclk generation**: Used to generate the master clock (mclk). The frequency of mclk is determined by the final bit duration of PWM generation module.
5. **mclk control**: Used as a metronome to co-ordinate the different functional blocks working synchronously.
6. **Reset and Enable**: Used to generate the reset and enable logic to different clock domains.
39.3 External Signals

The following table describes the external signals of MQS:

<table>
<thead>
<tr>
<th>Signal</th>
<th>Description</th>
<th>Pad</th>

</tr>
</tbody>
</table>
39.5  Programming Considerations

MQS has no internal programmable registers. But it does have some programmability from IOMUXC_GPR2.

<table>
<thead>
<tr>
<th>Register Bits</th>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IOMUXC_GPR2[26]</td>

</tr>
<tr>
<td></td>
<td></td>
<td>1—64, 0—32.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1—Enable MQS, 0—Disable MQS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>1—Enable software reset for MQS, 0—Exit software reset for MQS</td>
</tr>
<tr>
<td></td>
<td></td>
<td>0—mclk frequency = hmclk frequency; 1—mclk frequency = ½<em>hmclk frequency; 2—mclk frequency = 1/3</em>hmclk frequency; ...; n—mclk frequency = 1/(n+1)*hmclk frequency</td>
</tr>
</tbody>
</table>

39.5.1  Usage Model

Due to the different devices connected to MQS, and different high frequency behaviors of the connected analog circuits, the user needs choose the appropriate MQS_CLK_DIV and MQS_OVERSAMPLE values for the best audible effects.

40.2 Overview

The Sony/Philips Digital Interface (SPDIF) audio block is a stereo transceiver that allows the processor to receive and transmit digital audio.

The SPDIF transceiver allows the handling of both SPDIF channel status (CS) and User (U) data and includes a frequency measurement block that allows the precise measurement of an incoming sampling frequency.

A recovered clock is provided to drive both internal components in the system, such as SAI ports, and external components, such as A/Ds or D/As, with clocking control provided via related registers.
As the SPDIF internal data width is 24-bit, the eight most-significant bits of all registers return zeros.

The figure below shows a block diagram of the SPDIF transceiver data paths (receiver and transmitter) and its interface.
Figure 40-1. SPDIF Transceiver Data Interface Block Diagram
40.3 External Signals

</tbody>
</table>

40.5 Functional Description

The SPDIF is composed of two parts: SPDIF Receiver and SPDIF Transmitter.

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in the SPDIF Rx left and right FIFOs. The Channel Status and User Bits are also extracted from each frame and placed in the corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.
For the SPDIF transmitter, the audio data is provided by the processor via the SPDIFTxLeft and SPDIFTxRight registers. The Channel Status bits are also provided via the corresponding registers. The SPDIF transmitter generates a SPDIF output bitstream in the biphase mark format (IEC60958), which consists of audio data, channel status and user bits.

In the SPDIF transmitter, the IEC60958 biphase bit stream is generated on both edges of the SPDIF Transmit clock. The SPDIF Transmit clock is generated by the SPDIF internal clock generate block and the sources are from outside of the SPDIF block. For the SPDIF receiver, it can recover the SPDIF Rx clock. Figure 1 shows the clock structure of the SPDIF transceiver.

![Figure 40-2. SPDIF Transceiver Clock Diagram](image)

### 40.5.1 SPDIF Receiver

The SPDIF receiver extracts the audio data from each SPDIF frame and places the data in Rx left and right FIFOs.
The Tx left and right FIFOs are 16-deep and 24-bit-wide (equal to the audio data width). The Channel Status and User Bits are also extracted from each frame and placed in corresponding registers. The SPDIF receiver also provides a bypass option for direct transfer of the SPDIF input signal to the SPDIF transmitter.

The SPDIF receiver handles the main data audio stream and recovers the bit clock from the SPDIF input signal. The sample rate can be determined from the frequency measuring block. Additionally, the receiver supports the SPDIF C and U channels. The SPDIF C and U channel data is interfaced directly to memory-mapped registers.

All the data registers are controlled by the Interrupt Control Block and transferred to the memory-mapped IP bus.

The following functions are performed by the SPDIF receiver:

- Audio Data Reception see Audio Data Reception
- Channel Status bits Reception see Channel Status Reception
- U Channel bits Reception see User Bit Reception
- Validity Flag Reception see Validity Flag Reception
- SPDIF Receiver Exception support see SPDIF Receiver
- SPDIF Lock Detection

40.5.1.1 Audio Data Reception

The SPDIF Receiver block extracts the audio data from the IEC60958 stream, and outputs this via Rx left and right FIFOs to the memory-mapped registers SPDIFRxLeft and SPDIFRxRight.

Data from the SPDIF receiver is buffered in receive FIFO, and can be read by the processor from the memory-mapped registers.

- **SPDIF receiver data registers - Behavior on overrun, underrun**

The SPDIF Data Receive registers (SPDIFRxLeft and SPDIFRxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFOs. To prevent this from happening, hardware has been added to the device. Two mechanisms to prevent mismatch between the FIFOs are available.
If a SPDIF Data Rx FIFO overrun occurs on e.g. the right half of the FIFO, the sample that caused the overrun is not written to the right half (due to overrun). Special hardware will make sure the next sample is not written to the left half of the FIFO. If the overrun occurs on the left half of the FIFO, the next sample is not written to the right half of the FIFO.

- **SPDIF receiver data registers - Automatic resynchronization of FIFOs**

An automatic FIFO resynchronization feature is available. It can be enabled and disabled separately for every FIFO. If it is enabled, the hardware will check to see if the left and right FIFOs are in sync. If that is not the case, it will set the filling pointer of the right FIFO to be equal to the filling pointer of the left FIFO.

![State Diagram](image)

**Figure 40-3. FIFO Auto-resync Controller State Machine**

The operation is explained from the state diagram shown above. Every FIFO auto-resync controller has a state machine with 3 states: Off, StandBy and On. In the On state, the filling of the left FIFO is compared with the filling of right, and if they are not equal, right is made equal to left, and an interrupt is generated.

The controller will stay in Off state when the feature is disabled. When not disabled, the state machine will go to Off state on any processor read or write to the FIFO. It will go from On or Off to Standby on any left sample read from SPDIF Tx FIFOs, or on any left sample write to SPDIF Rx FIFOs. The controller will go from Standby to On on any right.
sample read from SPDIF Tx FIFO, or on any right sample write to SPDIF Rx FIFO. There is a control bit in the SPDIFConfig register to enable/disable the feature for the SPDIF Rx FIFO and SPDIF Tx FIFO.

### 40.5.1.1.1 Application Note

The automatic FIFO resynchronization can be switched on, and will avoid all mismatches between left and right FIFOs, if the software obeys the following rules: 1. When the left data is read or written to the left FIFO, in the same place of the program, data must be read or written to the right FIFO. Maximum time difference between left and right is 1/2 sample clock. (E.g. if sample frequency is 44 Khz, approximately 10 micro-seconds. For 88 Khz, approximately 5 micro-seconds.) 2. Write/read data to FIFO s at least 2 samples at the time. If there is a mismatch Left-Right, the resync logic may go on only 1 sample clock after last data is read/written to the FIFO. Also acceptable is polling the FIFO, if at least part of the time 2 samples will be read/written to it.

- **SPDIF receiver - Additional features**

There are three exceptions associated with the SPDIF Receivers FIFOs

- full
- under/overrun
- resync

When the "full" condition is set for processor data input registers, the processor should read data from the FIFO, before overrun occurs. When "full" is set, and the FIFO contains e.g. 6 samples, it is acceptable for the software to read first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 6 samples from the RIGHT address, followed by 6 samples from the LEFT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. There is no order specified.

The implementation for SPDIF Rx is a double FIFO, one for left and one for right. "full" is set when both FIFOs are full. "underrun, overrun" are set when one of the FIFOs do underrun or do overrun. The resync interrupt means hardware took special action to resynchronize left and right FIFOs.

The FIFO level at which the "full" interrupt is generated, is programmable via the Full Select field in the SPDIFConfigReg register.

**Rx FIFO on and Rx FIFO reset.**

Two additional control fields of the SPDIF Rx FIFO are the on/off select and FIFO reset fields.

If on/off select is set to off, all-zero will be read from the FIFO, irrespective of the data received over the SPDIF interface.
If FIFO reset is set, the FIFO is blocked at "1 sample in FIFO". In this, the full interrupt will be on if FullSelect is set to "00". If FullSelect is set to any other value, interrupt will be off. The other interrupts are always off.

40.5.1.2  Channel Status Reception

A total of 48 channel status bits are received in two registers. No interpretation is performed by the SPDIF receiver block.

Channel Status Bits are ordered first bit left. CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFRxCCChannel_h. CS-channel bit "23" is considered the LSB bit 0 in the register. C-channel bit 24 to 47 is seen as [23:0] bits of register SPDIFRxCCChannel_l.

40.5.1.2.1  Channel Status Interrupt

When the value of a new SPDIF "CS" channel status frame is loaded in the register, an interrupt is generated. The interrupt is cleared when the processor writes the corresponding bit in the InterruptStat register.

40.5.1.3  User Bit Reception

There are two modes for U Channel reception, CD and non-CD. As is decided by USyncMode (bit 1 of CDText_Control register).

- **Behavior of U Channel receive interface on incoming CD U Channel Sub-code in SPDIF receiver.**

This mode is selected if UsyncMode, bit 1 in register CD Text control is set "1".

The CD sub-code stream embedded into the SPDIF U channel consists of a sequence of packets. Every packet is made up 98 "symbols". The first two symbols of every packet are "sync symbols", the other 96 symbols are "data symbols".

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

Data symbols are coming in MSB first. The MSB is the leading one.

When a "long pause" is seen between 2 subsequent "data symbols", the SPDIF receiver will assume the reception of one or more "sync symbols". Table below gives details.
<table>
<thead>
<tr>
<th>Number of U Channel zero bits</th>
<th>Corresponding number of sync symbols</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-1</td>
<td>Unpredictable, not allowed</td>
</tr>
<tr>

<td>0</td>
</tr>
<tr>
<td>11-22</td>
<td>1</td>
</tr>
<tr>
<td>23-34</td>
<td>2</td>
</tr>
<tr>
<td>35-46</td>
<td>3</td>
</tr>
<tr>
<td>&gt;45</td>
<td>Unpredictable, not allowed</td>
</tr>
</tbody>
</table>

The recognition of the number of sync symbols derives from the fact that the U channel transmitter in the CD channel decoder will transmit one symbol on average every 12 SPDIF channel bits. On this average rate, there is a maximum tolerance of 5%.

The SPDIF receiver is tolerant of symbol errors. Due to the physical nature of the transmission of the data over the CD disc, not more than 1 out of any 5 consecutive user channel symbols may be in error. The error may cause a change in data value, which is not detected by this interface, or it may cause a data symbol to be seen as a sync symbol, or a sync symbol to be seen as a data symbol. However, not more than 1 out of any 5 consecutive user channel symbols should be affected in this way.

The SPDIF U channel circuitry recognizes the 98-symbol packet structure, and sends the 96 symbol payload to the processor application. The 96 symbol payload is transmitted to the processor via 2 registers:

- The SPDIFRxUChannel register. In this register, data is presented 3 symbols at the time to the processor. Every time 3 new valid symbols, received on the SPDIF U Channel are present, the UChannelRxFull interrupt is asserted. For one 98-symbol packet, 96 symbols are carried across SPDIFRxUChannel. To transfer all this data, 32 UChannelRxFull interrupts are generated.
- The QChannelReceive register. In this register, only the Q bit of the packet is accumulated. Operation is similar to UChannelReceive. Because only Q-bit is transferred, only 96 Q-bits are transferred for any 98-symbol packet. To transfer this data, 4 QChannelRxFull interrupts are generated. When QChannelRxFull occurs, it is coincident with UChannelRxFull. There is only one QChannelRxFull for every 8 UChannelRxFull. The convention is that most significant data is transmitted first, and is left-aligned in the registers.
- Timing regarding packet boundary is extracted by hardware. The last UChannelRxFull corresponding to a given packet should be coincident with the last QChannelRxFull. In this last U, Q channel interrupt, symbols 95-98 are received, Q channel bits 67-98. The interrupts are coincident with UQSyncFound, flagging last symbols of the current frame.
• When the start of the new packet is found before the current packet is complete (less than 98 symbols in the packet), the UQFrameError interrupt is set. The application software should read out UChannelReceive and QchannelReceive registers, discard the value, and assume the start of a new packet.

• As already said, packet sync extraction is tolerant for single-symbol errors. Packet sync detection is based on the recognition of the sequence data-sync-sync-data in the symbol stream, because this is the only syncing sequence that is not affected by single errors. If the sync symbols are not found 98 symbols after the previous occurrence, it is assumed to be destroyed by channel error, and a new sync symbols is interpolated.

• Normally, only data bytes are passed to the application software. Every databyte will have its most significant bit set. If sync symbols are passed to the application software, they are seen as all-zero symbols. Sync symbols can only end up in the data stream due to channel error.

• **Behavior of U Channel receive interface on incoming non-CD data.**

This mode is selected if UsyncMode, bit 1 in register CD Text control is set '0'.

In non-CD mode, the SPDIF U channel stream is recognized as a sequence of "data symbols". No packet recognition is done.

Any sequence found in the SPDIF U channel stream starting with a leading one, followed by 7 information bits, is recognized as a "data symbol". Subsequent data symbols are separated by "pauses". During the "pause", "zero bits" are seen on the SPDIF U channel.

3 consecutive data symbols seen in the SPDIF U Channel stream are grouped together into the SPDIFRxUChannel register. First symbol is left, last symbol is right aligned. When SPDIFRxUChannel contains 3 new data symbols, UChannelRxFull is asserted.

In this mode, the operation of QchannelRx and associated interrupt QchannelRxFull is reserved, undefined. And the operation of UQFrameError and UQSyncFound is also reserved, undefined.

The U channel is extracted, and output by the SPDIF Rx on SPDIFRxUChannel-Stream.

When incoming SPDIF data parity error or bit error is detected, and if the next SPDIF word for that channel is error-free, the SPDIF word in error is replaced with the average of the previous word and next word. When incoming SPDIF data parity error or bit error is detected, and the next SPDIF word is in error, the previous SPDIF word is repeated.
40.5.1.4 Validity Flag Reception

An interrupt is associated with the Validity flag. (interrupt 16 - SPDFValNoGood). This interrupt is set every time a frame is seen on the SPDIF interface with the validity bit set to "invalid".

40.5.1.5 SPDIF Receiver Interrupt Exception Definition

Several SPDIF exceptions can trigger an interrupt.

They are:

- Control Status channel change. Set when SPDIFRxChannel_1 register is updated. The register is updated for every new C-Channel received. The exception is reset on write to InterruptClear register.
- SPDIF Illegal Symbol. Set on reception of illegal symbol during SPDIF receive. Reset by writing register InterruptClear.
- SPDIF bit error. Set on reception of bit error. (Parity bit does not match). Reset on write to InterruptClear register.
- Receive data FIFO full. Set when SPDIF receive data FIFO is full.
- Receive data FIFO underrun/overrun. Set when there is a underrun/overrun on the SPDIF receive data FIFO.
- Receive data FIFO resynchronization. Set when a resynchronization event occurs on the SPDIF receive data FIFO.
- Receive U Channel buffer full. Set when next 24 bits of U channel code are available.
- Receive Q Channel buffer overrun. Set when Q channel buffer overrun.
- Receive U Channel buffer overrun. Set on U channel buffer overrun.
- Receive Q Channel buffer full. Set when next 24 bits of Q channel code are available.
- Receive UQ sync found. Set when UQ channel sync found.
- Receive UQ frame error. Set when UQ frame error found.

---

1. The SPDIF input is a bi-phase/mark modulated signal. The time between any two successive transitions of the SPDIF signal is always 1, 2 or 3 SPDIF symbol periods long. The SPDIF receiver will parse the stream, and split it in so-called symbols. It recognizes s1, s2 and s3 symbols, depending on the length of the symbols. Not all sequences of these symbols are allowed. To give an example, a sequence s2-s1-s1-s2 cannot occur in a no-error SPDIF signal. If the receiver finds such an illegal sequence, the illegal symbol interrupt is set. No corrective action is undertaken. When the interrupt occurs, this means that (a) The SPDIF signal is destroyed by noise (b) The SPDIF frequency changed.
40.5.1.6 Standards Compliance

The SPDIF interface is compatible with the Tech 3250-E standard of the European Broadcasting Union, except clause 6.3.3 and the IEC60958-3 Ed2 for relevant topics.

Supported input frequency range is 12 Khz up to 96 Khz. (fully compliant) and 96 Khz up to 176 Khz (Can interface with compliant SPDIF transmitter within same cabinet, making reasonable assumptions on jitter added due to interconnecting wire.)

Tolerated jitter on SPDIF input signals are 0.25 bit peak-peak for high frequencies. There is no jitter limit for low frequencies. The user channel extraction in CD mode is capable of coping with single-symbol errors, and still retrieve U channel frames on correct boundaries. This capability is required for reliable reception of CD-Text from some Philips CD channel decoders. This capability was deemed more important than compliance with the IEC60958 annex A.3 standard, and for this reason user channel reception is not compliant with IEC60958 annex A.3. However, the interface is capable to receive U channel inserted by a typical CD channel decoder. Also, in this case, it is more robust and tolerant for channel error than what is required by IEC60958 annex A.3.

40.5.1.7 SPDIF PLOCK Detection and Rxclk Output

Using the high speed system clock, the internal DPLL can extract the bit clock (advanced pulse) from the input bitstream. When this internal DPLL is locked, the LOCK bit of PhaseConfig Register will be set, and the SPDIF Lock output pin SPDIF_LOCK will be asserted.

After DPLL has locked, the pulses are generated, and the average pulse rate is 128 x the sampling frequency. (For a 44.1 Khz input sampling frequency, the average pulse rate = 128 x 44.1 Khz.) The pulse signal is used in the FreqMeas circuit to generate the frequency measurement result.

40.5.1.8 Measuring Frequency of SPDIF_RxClk

The internal DPLL can extract the bit clock (advanced plus) from the input bitstream. To do that, it is necessary to measure the frequency of the incoming signal in relationship with the system clock (BUS_CLK).

Associated with it are two registers, PhaseConfig and FreqMeas. The circuit will measure the frequency of the incoming clock as a function of the BUS_CLK. The circuit is a second-order filter. The output is a value represented by an unsigned number stored in the 24-bit FreqMeas register, giving the frequency of the source as a function of the BUS_CLK.
FreqMeas[23:0] = FreqMeas_CLK / BUS_CLK * 2^{10} * GAIN.

For example, if the GAIN is selected as 8*(2^{10}) (PhaseConfig[5:3] = 3'b011), the actual result
FreqMeas_CLK / BUS_CLK is equal to FreqMeas[23:0] / 2^{23}.

40.5.2  SPIDIF Transmitter

Audio data for the SPIDIF transmitter is provided by processor via the SPDIFTxLeft and SPDIFTxRight registers.

Clocking for SPIDIF transmitter is selected through a multiplexer from several clock sources (see TxClk_Source for clock source inputs). The SPIDIF transmitter clock source can be divided down as needed using Txclk_DF. The SPIDIF transmitter output can be chosen from either the SPIDIF transmitter block, directly from the SPIDIF receiver (via the output multiplexer), or disabled.

The SPIDIF transmitter generates a SPIDIF output bitstream in IEC60958 biphase mark format, consisting of audio data, channel status.

40.5.2.1  Audio Data Transmission

Audio data for the SPIDIF transmitter is provided by the processor via SPDIFTxLeft and SPDIFTxRight registers. They send audio data to Tx left and right FIFOs. The Tx left and right FIFOs are also 16-deep and 24-width (equal to the audio data width).

- **SPIDIF transmitter data registers - Behavior on overrun, underrun**

The SPIDIF Data Transmit registers (SPDIFTxLeft and SPDIFTxRight) have individual FIFOs for left and right channel. As a result, there is always the possibility that left and right FIFOs may go out of sync due to FIFO underruns and FIFO overruns that affect only one part (left or right) of any FIFO. To prevent this from happening, hardware has been added on the device. Two mechanisms to prevent mismatch between the FIFOs are available.

If SPIDIF Tx FIFO underruns on the right half of the FIFO, no sample leaves that FIFO (because it was already empty). Special hardware will make sure that the next sample read from the left FIFO will not leave the FIFO (no read strobe is generated). If the underrun occurs on the left half of the FIFO, next read strobe to the right FIFO is blocked.

- **SPIDIF transmitter data registers - Automatic resynchronization of FIFOs**
See Audio Data Reception.

- **SPDIFTxLeft, SPDIFTxRight details**

With SPDIF Tx FIFOs three exceptions are associated.

- empty
- under/overrun
- resync

When the empty condition is set for processor data output registers, the processor should write data to the FIFO, before underrun occurs. When empty is set and, for instance, 6 samples need to be written, it is acceptable for the software to write first 6 samples from the LEFT address, followed by 6 samples from the RIGHT address, or 1 sample LEFT, followed by 1 sample RIGHT repeated 6 times. Left should be written before right. The implementation of all data out FIFOs is a double FIFO, one for left and one for right. Empty is set when both FIFOs are empty. Underrun, overrun are set when one of the FIFOs do underrun or do overrun. Resync is set when the hardware resynchronizes left and right FIFOs.

On receiving underrun, overrun interrupt, synchronization between Left and Right words in the FIFOs may be lost. Synchronization will not be lost when the underrun or overrun comes from the IEC60958 side of the FIFO. If the processor reads or writes more data from, for example, left than from right, synchronization will be lost. If automatic resynchronization is enabled, and if the software obeys the rules to let this work, resynchronization will be automatic.

### 40.5.2.2 Channel Status Transmission

A total of 48 Consumer channel status bits are transmitted from two registers. Channel Status Bits are ordered first bit left.

CS-channel MSB bit "0" is located in bit position 23 in the memory-mapped register SPDIFTxCChannelCons_h. CS-channel bit "23" is considered bit 0 in the register. C-channel bits 24-47 are seen as MSB-LSB bits of register SPDIFTxCChannelCons_l.

### 40.5.2.3 Validity Flag Transmission

The validity bit setting is performed via bit 5 of the SPDIF_SCR register.

41.2 Introduction

The MAC-NET core, in conjunction with a 10/100-Mbit/s MAC, implements layer 3 network acceleration functions. These functions are designed to accelerate the processing of various common networking protocols, such as IP, TCP, UDP, and ICMP, providing wire speed services to client applications.

41.3 Overview

The core implements a dual-speed 10/100-Mbit/s Ethernet MAC compliant with the IEEE802.3-2002 standard. The MAC layer provides compatibility with half- or full-duplex 10/100-Mbit/s Ethernet LANs.
The MAC operation is fully programmable and can be used in Network Interface Card (NIC), bridging, or switching applications. The core implements the remote network monitoring (RMON) counters according to IETF RFC 2819.

The core also implements a hardware acceleration block to optimize the performance of network controllers providing TCP/IP, UDP, and ICMP protocol services. The acceleration block performs critical functions in hardware, which are typically implemented with large software overhead.

The core implements programmable embedded FIFOs that can provide buffering on the receive path for lossless flow control.

Advanced power management features are available with magic packet detection and programmable power-down modes.

A unified DMA (uDMA), internal to the ENET module, optimizes data transfer between the ENET core and the SoC, and supports an enhanced buffer descriptor programming model to support IEEE 1588 functionality.

The programmable Ethernet MAC with IEEE 1588 integrates a standard IEEE 802.3 Ethernet MAC with a time-stamping module. The IEEE 1588 standard provides accurate clock synchronization for distributed control nodes for industrial automation applications.

### 41.3.1 Features

The MAC-NET core includes the following features.

#### 41.3.1.1 Ethernet MAC features

- Implements the full 802.3 specification with preamble/SFD generation, frame padding generation, CRC generation and checking
- Supports zero-length preamble
- Dynamically configurable to support 10/100-Mbit/s operation
- Supports 10/100 Mbit/s full-duplex and configurable half-duplex operation
- Compliant with the AMD magic packet detection with interrupt for node remote power management
- Seamless interface to commercial ethernet PHY devices via one of the following:
  - a 4-bit Media Independent Interface (MII) operating at 2.5/25 MHz.
  - a 4-bit non-standard MII-Lite (MII without the CRS and COL signals) operating at 2.5/25 MHz.
  - a 2-bit Reduced MII (RMII) operating at 50 MHz.
- Simple 64-Bit FIFO user-application interface
- CRC-32 checking at full speed with optional forwarding of the frame check sequence (FCS) field to the client
- CRC-32 generation and append on transmit or forwarding of user application provided FCS selectable on a per-frame basis
- In full-duplex mode:
  - Implements automated pause frame (802.3 x31A) generation and termination, providing flow control without user application intervention
  - Pause quanta used to form pause frames — dynamically programmable
  - Pause frame generation additionally controllable by user application offering flexible traffic flow control
  - Optional forwarding of received pause frames to the user application
  - Implements standard flow-control mechanism
- In half-duplex mode: provides full collision support, including jamming, backoff, and automatic retransmission
- Supports VLAN-tagged frames according to IEEE 802.1Q
- Programmable MAC address: Insertion on transmit; discards frames with mismatching destination address on receive (except broadcast and pause frames)
- Programmable promiscuous mode support to omit MAC destination address checking on receive
- Multicast and unicast address filtering on receive based on 64-entry hash table, reducing higher layer processing load
- Programmable frame maximum length providing support for any standard or proprietary frame length
- Statistics indicators for frame traffic and errors (alignment, CRC, length) and pause frames providing for IEEE 802.3 basic and mandatory management information database (MIB) package and remote network monitoring (RFC 2819)
- Simple handshake user application FIFO interface with fully programmable depth and threshold levels
- Provides separate status word for each received frame on the user interface providing information such as frame length, frame type, VLAN tag, and error information
- Multiple internal loopback options
- MDIO master interface for PHY device configuration and management supports two programmable MDIO base addresses, and standard (IEEE 802.3 Clause 22) and extended (Clause 45) MDIO frame formats
- Supports legacy FEC buffer descriptors
- Interrupt coalescing reduces the number of interrupts generated by the MAC, reducing CPU loading
41.3.1.2  **IP protocol performance optimization features**

- Operates on TCP/IP and UDP/IP and ICMP/IP protocol data or IP header only
- Enables wire-speed processing
- Supports IPv4 and IPv6
- Transparent passing of frames of other types and protocols
- Supports VLAN tagged frames according to IEEE 802.1q with transparent forwarding of VLAN tag and control field
- Automatic IP-header and payload (protocol specific) checksum calculation and verification on receive
- Automatic IP-header and payload (protocol specific) checksum generation and automatic insertion on transmit configurable on a per-frame basis
- Supports IP and TCP, UDP, ICMP data for checksum generation and checking
- Supports full header options for IPv4 and TCP protocol headers
- Provides IPv6 support to datagrams with base header only — datagrams with extension headers are passed transparently unmodified/unchecked
- Provides statistics information for received IP and protocol errors
- Configurable automatic discard of erroneous frames
- Configurable automatic host-to-network (RX) and network-to-host (TX) byte order conversion for IP and TCP/UDP/ICMP headers within the frame
- Configurable padding remove for short IP datagrams on receive
- Configurable Ethernet payload alignment to allow for 32-bit word-aligned header and payload processing
- Programmable store-and-forward operation with clock and rate decoupling FIFOs

41.3.1.3  **IEEE 1588 features**

- Supports all IEEE 1588 frames.
- Allows reference clock to be chosen independently of network speed.
- Software-programmable precise time-stamping of ingress and egress frames
- Timer monitoring capabilities for system calibration and timing accuracy management
- Precise time-stamping of external events with programmable interrupt generation
- Programmable event and interrupt generation for external system control
- Supports hardware- and software-controllable timer synchronization.
- Provides a 4-channel IEEE 1588 timer. Each channel supports input capture and output compare using the 1588 counter.

41.6 Memory map/register definition

ENET registers must be read or written with 32-bit accesses. Non-32 bit accesses will terminate with an error.

Reserved bits should be written with 0 and ignored on read. Unused registers read zero and a write has no effect.

This table shows Ethernet registers organization.

41.6.1 Interrupt Event Register (ENETx_EIR)

When an event occurs that sets a bit in EIR, an interrupt occurs if the corresponding bit in the interrupt mask register (EIMR) is also set. Writing a 1 to an EIR bit clears it; writing 0 has no effect. This register is cleared upon hardware reset.

**NOTE**

TxBD[INT] and RxBD[INT] must be set to 1 to allow setting the corresponding EIR register flags in enhanced mode, ENET_ECR[EN1588] = 1. Legacy mode does not require these flags to be enabled.

</table>
| 18 PLR | Payload Receive Error  
Indicates a frame was received with a payload length error. See Frame Length/Type Verification: Payload Length Check for more information. |
| 17 WAKEUP | Node Wakeup Request Indication  
Read-only status bit to indicate that a magic packet has been detected. Will act only if ECR[MAGICEN] is set. |
| 16 TS_AVAIL | Transmit Timestamp Available  
Indicates that the timestamp of the last transmitted timing frame is available in the ATSTMP register. |
| 15 TS_TIMER | Timestamp Timer  
The adjustable timer reached the period event. A period event interrupt can be generated if ATCR[PEREN] is set and the timer wraps according to the periodic setting in the ATPER register. Set the timer period value before setting ATCR[PEREN]. |

41.6.2 Interrupt Mask Register (ENETx_EIMR)

EIMR controls which interrupt events are allowed to generate actual interrupts. A hardware reset clears this register. If the corresponding bits in the EIR and EIMR registers are set, an interrupt is generated. The interrupt signal remains asserted until a 1 is written to the EIR field (write 1 to clear) or a 0 is written to the EIMR field.

<tbody>
<tr>
<td>0</td>
<td>The corresponding interrupt source is masked.</td>
</tr>
<tr>
<td>1</td>
<td>The corresponding interrupt source is not masked.</td>
</tr>
</tbody>
</table>

27 TXF

TXF Interrupt Mask
Corresponds to interrupt source EIR[TXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

0 The corresponding interrupt source is masked.
1 The corresponding interrupt source is not masked.

26 TXB

TXB Interrupt Mask
Corresponds to interrupt source EIR[TXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

0 The corresponding interrupt source is masked.
1 The corresponding interrupt source is not masked.

25 RXF

RXF Interrupt Mask
Corresponds to interrupt source EIR[RXF] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXF field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

24 RXB

RXB Interrupt Mask
Corresponds to interrupt source EIR[RXB] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RXB field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

23 MII

MII Interrupt Mask
Corresponds to interrupt source EIR[MII] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR MII field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

22 EBERR

EBERR Interrupt Mask
Corresponds to interrupt source EIR[EBERR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR EBERR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

21 LC

LC Interrupt Mask
Corresponds to interrupt source EIR[LC] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR LC field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared.

| 20 RL | RL Interrupt Mask  
Corresponds to interrupt source EIR[RL] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR RL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. |
| 19 UN | UN Interrupt Mask  
Corresponds to interrupt source EIR[UN] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR UN field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. |
| 18 PLR | PLR Interrupt Mask  
Corresponds to interrupt source EIR[PLR] and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR PLR field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. |
| 17 WAKEUP | WAKEUP Interrupt Mask  
Corresponds to interrupt source EIR[WAKEUP] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR WAKEUP field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. |
| 16 TS_AVAIL | TS_AVAIL Interrupt Mask  
Corresponds to interrupt source EIR[TS_AVAIL] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_AVAIL field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. |
| 15 TS_TIMER | TS_TIMER Interrupt Mask  
Corresponds to interrupt source EIR[TS_TIMER] register and determines whether an interrupt condition can generate an interrupt. At every module clock, the EIR samples the signal generated by the interrupting source. The corresponding EIR TS_TIMER field reflects the state of the interrupt signal even if the corresponding EIMR field is cleared. |

<tr>
<td>9 Reserved</td>
<td>This field is reserved. Always write 0 to this field.</td>
</tr>
</tbody>
</table>
| 8 DBSWP | Descriptor Byte Swapping Enable  
Swaps the byte locations of the buffer descriptors.  
**NOTE:** This field must be written to 1 after reset.  
0 The buffer descriptor bytes are not swapped to support big-endian devices.  
1 The buffer descriptor bytes are swapped to support little-endian devices. |
| 7 Reserved | This field is reserved. Always write 0 to this field. |
| 6 DBGEN | Debug Enable  
Enables the MAC to enter hardware freeze mode when the device enters debug mode.  
0 MAC continues operation in debug mode.  
1 MAC enters hardware freeze mode when the processor is in debug mode. |
| 5 Reserved | This field is reserved. This write-only field is reserved. It must always be written with the value 0. |
| 4 EN1588 | EN1588 Enable  
Enables enhanced functionality of the MAC.  
0 Legacy FEC buffer descriptors and functions enabled.  
1 Enhanced frame time-stamping functions enabled. |
| 3 SLEEP | Sleep Mode Enable  
0 Normal operating mode.  
1 Sleep mode. |
| 2 MAGICEN | Magic Packet Detection Enable  
Enables/disables magic packet detection.  
**NOTE:** MAGICEN is relevant only if the SLEEP field is set. If MAGICEN is set, changing the SLEEP field enables/disables sleep mode and magic packet detection.  
**NOTE:** EIMR[WAKEUP] must be written to one if Magic packet wakeup is programmed to wake up the chip from low power mode.  
0 Magic detection logic disabled.  
1 The MAC core detects magic packets and asserts EIR[WAKEUP] when a frame is detected. |

<tr>
<td>1 ETHERN</td>
<td>Ethernet Enable</td>
</tr>
<tr>
<td>Enables/disables the Ethernet MAC. When the MAC is disabled, the buffer descriptors for an aborted transmit frame are not updated. The uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers. Hardware clears this field under the following conditions:</td>
<td></td>
</tr>
<tr>
<td>• RESET is set by software</td>
<td></td>
</tr>
<tr>
<td>• An error condition causes the EBERR field to set.</td>
<td></td>
</tr>
</tbody>
</table>

**NOTE:**

- ETHERN must be set at the very last step during ENET configuration/setup-initialization, only after all other ENET-related registers have been configured.
- If ETHERN is cleared to 0 by software then next time ETHERN is set, the EIR interrupts must cleared to 0 due to previous pending interrupts.

| 0 Reception immediately stops and transmission stops after a bad CRC is appended to any currently transmitted frame. |
| 1 MAC is enabled, and reception and transmission are possible. |

| 0 RESET | Ethernet MAC Reset |
| When this field is set, it clears the ETHERN field. |

### 41.6.6 MII Management Frame Register (ENETx_MMFR)

Writing to MMFR triggers a management frame transaction to the PHY device unless MSCR is programmed to zero.

If MSCR is changed from zero to non-zero during a write to MMFR, an MII frame is generated with the data previously written to the MMFR. This allows MMFR and MSCR to be programmed in either order if MSCR is currently zero.

If the MMFR register is written while frame generation is in progress, the frame contents are altered. Software must use the EIR[MII] interrupt indication to avoid writing to the MMFR register while frame generation is in progress.

**41.6.7 MII Speed Control Register (ENETx_MSCR)**

MSCR provides control of the MII clock (MDC pin) frequency and allows a preamble drop on the MII management frame.

The MII_SPEED field must be programmed with a value to provide an MDC frequency of less than or equal to 2.5 MHz to be compliant with the IEEE 802.3 MII specification. The MII_SPEED must be set to a non-zero value to source a read or write management frame. After the management frame is complete, the MSCR register may optionally be cleared to turn off MDC. The MDC signal generated has a 50% duty cycle except when MII_SPEED changes during operation. This change takes effect following a rising or falling edge of MDC.

For example, if the internal module clock (that is, peripheral bus clock) is 25 MHz, programming MII_SPEED to 0x4 results in an MDC as given in the following equation:

\[
\text{MII clock frequency} = \frac{25 \text{ MHz}}{((4 + 1) \times 2)} = 2.5 \text{ MHz}
\]

The following table shows the optimum values for MII_SPEED as a function of IPS bus clock frequency.

10–8 HOLDTIME

Hold time On MDIO Output

IEEE802.3 clause 22 defines a minimum of 10 ns for the hold time on the MDIO output. Depending on the host bus frequency, the setting may need to be increased.

000 1 internal module clock cycle
001 2 internal module clock cycles
010 3 internal module clock cycles
111 8 internal module clock cycles

7 DIS_PRE

Disable Preamble

Enables/disables prepending a preamble to the MII management frame. The MII standard allows the preamble to be dropped if the attached PHY devices do not require it.

0 Preamble enabled.
1 Preamble (32 ones) is not prepended to the MII management frame.

6–1 MII_SPEED

MII Speed

Controls the frequency of the MII management interface clock (MDC) relative to the internal module clock. A value of 0 in this field turns off MDC and leaves it in low voltage state. Any non-zero value results in the MDC frequency of:

1/(MII_SPEED + 1) x 2) of the internal module clock frequency

0 Reserved

This field is reserved. This read-only field is reserved and always has the value 0.
41.6.8 MIB Control Register (ENETx_MIBC)

MIBC is a read/write register controlling and observing the state of the MIB block. Access this register to disable the MIB block operation or clear the MIB counters. The MIB_DIS field resets to 1.

41.6.9  Receive Control Register (ENETx_RCR)

Address: 402D_4000h base + 84h offset = 402D_4084h
## ENETx_RCR field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31 GRS | Graceful Receive Stopped  
Read-only status indicating that the MAC receive datapath is stopped. |
| 30 NLC | Payload Length Check Disable  
Enables/disables a payload length check.  
0 The payload length check is disabled.  
1 The core checks the frame's payload length with the frame length/type field. Errors are indicated in the EIR[PLR] field. |
| 29–16 MAX_FL | Maximum Frame Length  
Resets to decimal 1518. Length is measured starting at DA and includes the CRC at the end of the frame. Transmit frames longer than MAX_FL cause the BABT interrupt to occur. Receive frames longer than MAX_FL cause the BABR interrupt to occur and set the LG field in the end of frame receive buffer descriptor. The recommended default value to be programmed is 1518 or 1522 if VLAN tags are supported. |
| 15 CFEN | MAC Control Frame Enable  
Enables/disables the MAC control frame.  
0 MAC control frames with any opcode other than 0x0001 (pause frame) are accepted and forwarded to the client interface.  
1 MAC control frames with any opcode other than 0x0001 (pause frame) are silently discarded. |
| 14 CRCFWD | Terminate/Forward Received CRC  
Specifies whether the CRC field of received frames is transmitted or stripped.  
**NOTE:** If padding function is enabled (PADEN = 1), CRCFWD is ignored and the CRC field is checked always terminated and removed.  
0 The CRC field of received frames is transmitted to the user application.  
1 The CRC field is stripped from the frame. |
| 13 PAUFWD | Terminate/Forward Pause Frames  
Specifies whether pause frames are terminated or forwarded.  
0 Pause frames are terminated and discarded in the MAC.  
1 Pause frames are forwarded to the user application. |
| 12 PADEN | Enable Frame Padding Remove On Receive  
Specifies whether the MAC removes padding from received frames.  
0 No padding is removed on receive by the MAC.  
1 Padding is removed from received frames. |
| 11–10 Reserved | This field is reserved.  
This write-only field is reserved. It must always be written with the value 0. |
| 9 RMII_10T | Enables 10-Mbit/s mode of the RMII  
0  100-Mbit/s operation.  
1  10-Mbit/s operation. |

<td>MII_MODE &lt;br&gt;Media Independent Interface Mode &lt;br&gt;This field must always be set. &lt;br&gt;0 Reserved. &lt;br&gt;1 MII or RMII mode, as indicated by the RMII_MODE field.</td>
</tr>
<tr>
<td>1</td>
<td>DRT &lt;br&gt;Disable Receive On Transmit &lt;br&gt;0 Receive path operates independently of transmit (i.e., full-duplex mode). Can also be used to monitor transmit activity in half-duplex mode. &lt;br&gt;1 Disable reception of frames while transmitting. (Normally used for half-duplex mode.)</td>
</tr>
<tr>
<td>0</td>
<td>LOOP &lt;br&gt;Internal Loopback &lt;br&gt;This is an MII internal loopback, therefore MII_MODE must be written to 1 and RMII_MODE must be written to 0. &lt;br&gt;0 Loopback disabled. &lt;br&gt;1 Transmitted frames are looped back internal to the device and transmit MII output signals are not asserted. DRT must be cleared.</td>
</tr>
</tbody>
</table>
41.6.10 Transmit Control Register (ENETx_TCR)

TCR is read/write and configures the transmit block. This register is cleared at system reset. FDEN can only be modified when ECR[ETHEREN] is cleared.

Address: 402D_4000h base + C4h offset = 402D_40C4h

<table>

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 0     | TxBD[TC] controls whether the frame has a CRC from the application.  
| 1     | The transmitter does not append any CRC to transmitted frames, as it is expecting a frame with CRC from the application. |
| 8     | ADDINS Set MAC Address On Transmit  
|       | 0 The source MAC address is not modified by the MAC.  
|       | 1 The MAC overwrites the source MAC address with the programmed MAC address according to ADDSEL. |
| 7–5   | ADDSEL Source MAC Address Select On Transmit  
|       | If ADDINS is set, indicates the MAC address that overwrites the source MAC address.  
| 000   | Node MAC address programmed on PADDR1/2 registers.  
| 100   | Reserved.  
| 101   | Reserved.  
| 110   | Reserved. |
| 4     | RFC_PAUSE Receive Frame Control Pause  
|       | This status field is set when a full-duplex flow control pause frame is received and the transmitter pauses for the duration defined in this pause frame. This field automatically clears when the pause duration is complete. |
| 3     | TFC_PAUSE Transmit Frame Control Pause  
|       | Pauses frame transmission. When this field is set, EIR[GRA] is set. With transmission of data frames stopped, the MAC transmits a MAC control PAUSE frame. Next, the MAC clears TFC_PAUSE and resumes transmitting data frames. If the transmitter pauses due to user assertion of GTS or reception of a PAUSE frame, the MAC may continue transmitting a MAC control PAUSE frame.  
| 0     | No PAUSE frame transmitted.  
| 1     | The MAC stops transmission of data frames after the current transmission is complete. |
| 2     | FDEN Full-Duplex Enable  
|       | If this field is set, frames transmit independent of carrier sense and collision inputs. Only modify this bit when ECR[ETHEREN] is cleared. |
| 1     | Reserved  
|       | This write-only field is reserved. It must always be written with the value 0. |
| 0     | GTS Graceful Transmit Stop  
|       | When this field is set, MAC stops transmission after any frame currently transmitted is complete and EIR[GRA] is set. If frame transmission is not currently underway, the GRA interrupt is asserted immediately. After transmission finishes, clear GTS to restart. The next frame in the transmit FIFO is then transmitted. If an early collision occurs during transmission when GTS is set, transmission stops after the collision. The frame is transmitted again after GTS is cleared. There may be old frames in the transmit FIFO that transmit when GTS is reasserted. To avoid this, clear ECR[ETHEREN] following the GRA interrupt. |
41.6.11 Physical Address Lower Register (ENETx_PALR)

PALR contains the lower 32 bits (bytes 0, 1, 2, 3) of the 48-bit address used in the address recognition process to compare with the destination address (DA) field of receive frames with an individual DA. In addition, this register is used in bytes 0 through 3 of the six-byte source address field when transmitting PAUSE frames.

41.6.13 Opcode/Pause Duration Register (ENETx_OPD)

OPD is read/write accessible. This register contains the 16-bit opcode and 16-bit pause duration fields used in transmission of a PAUSE frame. The opcode field is a constant value, 0x0001. When another node detects a PAUSE frame, that node pauses transmission for the duration specified in the pause duration field. The lower 16 bits of this register are not reset and you must initialize it.

41.6.20 Transmit FIFO Watermark Register (ENETx_TFWR)

If TFWR[STRFWD] is cleared, TFWR[TFWR] controls the amount of data required in the transmit FIFO before transmission of a frame can begin. This allows you to minimize transmit latency (TFWR = 00 or 01) or allow for larger bus access latency (TFWR = 11) due to contention for the system bus. Setting the watermark to a high value minimizes the risk of transmit FIFO underrun due to contention for the system bus. The byte counts associated with the TFWR field may need to be modified to match a given system requirement, for example, worst-case bus access latency by the transmit data uDMA channel.

When the FIFO level reaches the value the TFWR field and when the STR_FWD is set to ‘0’, the MAC transmit control logic starts frame transmission even before the end-of-frame is available in the FIFO (cut-through operation).

If a complete frame has a size smaller than the threshold programmed with TFWR, the MAC also transmits the Frame to the line.

To enable store and forward on the Transmit path, set STR_FWD to ‘1’ In this case, the MAC starts to transmit data only when a complete frame is stored in the Transmit FIFO.
41.6.21 Receive Descriptor Ring Start Register (ENETx_RDSR)

RDSR points to the beginning of the circular receive buffer descriptor queue in external memory. This pointer must be 64-bit aligned (bits 2–0 must be zero); however, for optimal performance the pointer should be 512-bit aligned, that is, evenly divisible by 64.

**NOTE**

This register must be initialized prior to operation
Address: 402D_4000h base + 180h offset = 402D_4180h

### 41.6.23 Maximum Receive Buffer Size Register (ENETx_MRBR)

The MRBR is a user-programmable register that dictates the maximum size of all receive buffers. This value should take into consideration that the receive CRC is always written into the last receive buffer.

- **R_BUF_SIZE** is concatenated with the four least-significant bits of this register and are used as the maximum receive buffer size.
- To allow one maximum size frame per buffer, MRBR must be set to RCR[MAX_FL] or larger.
- To properly align the buffer, MRBR must be evenly divisible by 64. To ensure this, set the lower two bits of **R_BUF_SIZE** to zero. The lower four bits of this register are already set to zero by the device.
- To minimize bus usage (descriptor fetches), set MRBR greater than or equal to 256 bytes.

**NOTE**
This register must be initialized before operation.

Address: 402D_4000h base + 188h offset = 402D_4188h

**RX_ALMOST_EMPTY** Value Of The Receive FIFO Almost Empty Threshold

Value, in 64-bit words, of the receive FIFO almost empty threshold. When the FIFO level reaches the value programmed in this field and the end-of-frame has not been received for the frame yet, the core receive read control stops FIFO read (and subsequently stops transferring data to the MAC client application). It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO. A minimum value of 4 should be set.

### 41.6.27 Receive FIFO Almost Full Threshold (ENETx_RAFL)

Address: 402D_4000h base + 19Ch offset = 402D_419Ch

41.6.30  Transmit FIFO Almost Full Threshold (ENETx_TAFL)

Address: 402D_4000h base + 1A8h offset = 402D_41A8h

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–8</td>
<td>Reserved</td>
</tr>
<tr>
<td>TX_ALMOST_FULL</td>
<td>Value Of The Transmit FIFO Almost Full Threshold</td>
</tr>
</tbody>
</table>

Value, in 64-bit words, of the transmit FIFO almost full threshold. A minimum value of six is required. A recommended value of at least 8 should be set allowing a latency of two clock cycles to the application. If more latency is required the value can be increased as necessary (latency = TAFL - 5).

When the FIFO level comes close to the maximum, so that there is no more space for at least TX_ALMOST_FULL number of words, the pin ff_tx_rdy is deasserted. If the application does not react on this signal, the FIFO write control logic, to avoid FIFO overflow, truncates the current frame and sets the error status. As a result, the frame will be transmitted with an GMII/MII error indication. See Transmit FIFO for more information.

NOTE: A FIFO overflow is a fatal error and requires a global reset on the transmit datapath or at least deassertion of ETHEREN.

41.6.31  Transmit Inter-Packet Gap (ENETx_TIPG)

Address: 402D_4000h base + 1ACh offset = 402D_41ACh

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–5</td>
<td>Reserved</td>
</tr>
<tr>
<td>IPG</td>
<td>Transmit Inter-Packet Gap</td>
</tr>
</tbody>
</table>

Indicates the IPG, in bytes, between transmitted frames. Valid values range from 8 to 26. If the written value is less than 8 or greater than 26, the internal (effective) IPG is 12.

NOTE: The IPG value read will be the value that was written, even if it is out of range.
41.6.32  Frame Truncation Length (ENETx_FTRL)

Address: 402D_4000h base + 1B0h offset = 402D_41B0h

| Bit | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

</tr>
</tbody>
</table>

41.6.33  Transmit Accelerator Function Configuration (ENETx_TACC)

TACC controls accelerator actions when sending frames. The register can be changed before or after each frame, but it must remain unmodified during frame writes into the transmit FIFO.

The TFWR[STRFWD] field must be set to use the checksum feature.

Address: 402D_4000h base + 1C0h offset = 402D_41C0h

| Bit | 31  | 30  | 29  | 28  | 27  | 26  | 25  | 24  | 15  | 14  | 13  | 12  | 11  | 10  | 9   | 8   | 7   | 6   | 5   | 4   | 3   | 2   | 1   | 0   |

### ENETx_TACC field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31–5  | Reserved
|       | This field is reserved. This write-only field is reserved. It must always be written with the value 0. |
| 4     | PROCHK
|       | Enables insertion of protocol checksum.  
|       | 0  Checksum not inserted.  
|       | 1  If an IP frame with a known protocol is transmitted, the checksum is inserted automatically into the frame. The checksum field must be cleared. The other frames are not modified. |
| 3     | IPCHK
|       | Enables insertion of IP header checksum.  
|       | 0  Checksum is not inserted.  
|       | 1  If an IP frame is transmitted, the checksum is inserted automatically. The IP header checksum field must be cleared. If a non-IP frame is transmitted the frame is not modified. |
| 2–1   | Reserved
|       | This field is reserved. This write-only field is reserved. It must always be written with the value 0. |
| 0     | SHIFT16
|       | TX FIFO Shift-16  
|       | 0  Disabled.  
|       | 1  Indicates to the transmit data FIFO that the written frames contain two additional octets before the frame data. This means the actual frame begins at bit 16 of the first word written into the FIFO. This function allows putting the frame payload on a 32-bit boundary in memory, as the 14-byte Ethernet header is extended to a 16-byte header. |

41.6.88  Octet Count for Frames Received without Error Statistic Register (ENETx_IEEE_R_OCTETS_OK)

Address: 402D_4000h base + 2E0h offset = 402D_42E0h

ENETx_IEEE_R_OCTETS_OK field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>COUNT</td>
<td>Number of octets for frames received without error</td>
</tr>
</tbody>
</table>
| NOTE:| Counts total octets (includes header and FCS fields). Does not increment for the broadcast frames when broadcast reject is enabled and promiscuous mode is disabled within the receive control register (RCR).

41.6.89  Adjustable Timer Control Register (ENETx_ATCR)

ATCR command fields can trigger the corresponding events directly. It is not necessary to preserve any of the configuration fields when a command field is set in the register, that is, no read-modify-write is required.

NOTE

The CAPTURE and RESTART fields and bits 12 and 10 must be 0 in order to write to the other fields in this register.

Address: 402D_4000h base + 400h offset = 402D_4400h
## ENETx_ATCR field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–14 Reserved</td>
<td>This field is reserved. This read-only field is reserved and always has the value 0.</td>
</tr>
</tbody>
</table>
| 13 SLAVE | Enable Timer Slave Mode  
0 The timer is active and all configuration fields in this register are relevant.  
1 The internal timer is disabled and the externally provided timer value is used. All other fields, except CAPTURE, in this register have no effect. CAPTURE can still be used to capture the current timer value. |
| 12 Reserved | This field is reserved. Always write 0 to this field. |
| 11 CAPTURE | Capture Timer Value  
When this field is set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes.  
0 No effect.  
1 The current time is captured and can be read from the ATVR register. |
| 10 Reserved | This field is reserved. Always write 0 to this field. |
| 9 RESTART | Reset Timer  
Resets the timer to zero. This has no effect on the counter enable. If the counter is enabled when this field is set, the timer is reset to zero and starts counting from there. When set, all other fields are ignored during a write. This field automatically clears to 0 after the command completes. RESTART should be used when the timer is enabled. |
| 8 Reserved | This field is reserved. |
| 7 PINPER | Enables event signal output assertion on period event.  
**NOTE**: Not all devices contain the event signal output. See the chip configuration details.  
0 Disable.  
1 Enable. |
| 6 Reserved | This field is reserved. |
| 5 Reserved | This field is reserved.  
**NOTE**: This field must be written always with one. |
| 4 PEREN | Enable Periodical Event |

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFFSET</td>
<td>Offset value for one-shot event generation. When the timer reaches the value, an event can be generated to reset the counter. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds.</td>
</tr>
</tbody>
</table>

### 41.6.92 Timer Period Register (ENETx_ATPER)

Address: 402D_4000h base + 40Ch offset = 402D_440Ch

#### ENETx_ATPER field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| PERIOD | Value for generating periodic events. Each instance the timer reaches this value, the period event occurs and the timer restarts. If the increment value in ATINC is given in true nanoseconds, this value is also given in true nanoseconds. The value should be initialized to 1,000,000,000 (1×10⁹) to represent a timer wrap around of one second. The increment value set in ATINC should be set to the true nanoseconds of the period of clock ts_clk, hence implementing a true 1 second counter.  

**NOTE:** The value of PERIOD has the following constraint:  
\[ 2^{32} - \text{ENET_ATINC}[\text{INC\_COR}] - 3 \times \text{ENET_ATINC}[\text{INC}] \geq \text{PERIOD} > 0. \]

</thead>
<tbody>
<tr>
<td>TCC</td>
<td>Timer Capture Compare</td>
</tr>
<tr>
<td></td>
<td>This register is double buffered between the module clock and 1588 clock domains.</td>
</tr>
<tr>
<td></td>
<td>When configured for compare, the 1588 clock domain updates with the value in the module clock domain whenever the Timer Channel is first enabled and on each subsequent compare. Write to this register with the first compare value before enabling the Timer Channel. When the Timer Channel is enabled, write the second compare value either immediately, or at least before the first compare occurs. After each compare, write the next compare value before the previous compare occurs and before clearing the Timer Flag.</td>
</tr>
</tbody>
</table>
ENET<sub>x</sub>_TCCR<sub>n</sub> field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>The compare occurs one 1588 clock cycle after the IEEE 1588 Counter increments past the compare value in the 1588 clock domain. If the compare value is less than the value of the 1588 Counter when the Timer Channel is first enabled, then the compare does not occur until following the next overflow of the 1588 Counter. If the compare value is greater than the IEEE 1588 Counter when the 1588 Counter overflows, or the compare value is less than the value of the IEEE 1588 Counter after the overflow, then the compare occurs one 1588 clock cycle following the overflow. When configured for capture, the value of the IEEE 1588 Counter is captured into the 1588 clock domain and then updated into the module clock domain, provided the Timer Flag is clear. Always read the capture value before clearing the Timer Flag.</td>
</tr>
</tbody>
</table>

41.7 Functional description

This section provides a complete functional description of the MAC-NET core.

41.7.1 Ethernet MAC frame formats

The IEEE 802.3 standard defines the Ethernet frame format as follows:

- Minimum length of 64 bytes
- Maximum length of 1518 bytes excluding the preamble and the start frame delimiter (SFD) bytes

An Ethernet frame consists of the following fields:

- Seven bytes preamble
- Start frame delimiter (SFD)
- Two address fields
- Length or type field
- Data field
- Frame check sequence (CRC value)
Optionally, MAC frames can be VLAN-tagged with an additional four-byte field inserted between the MAC source address and the type/length field. VLAN tagging is defined by the IEEE P802.1q specification. VLAN-tagged frames have a maximum length of 1522 bytes, excluding the preamble and the SFD bytes.

**Figure 41-3. VLAN-tagged MAC frame format overview**

**Table 41-6. MAC frame definition**

<table>
<thead>
<tr>
<th>Term</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frame length</td>
<td>Defines the length, in octets, of the complete frame without preamble and SFD. A frame has a valid length if it contains at least 64 octets and does not exceed the programmed maximum length.</td>
</tr>
<tr>
<td>Payload length</td>
<td>The length/type field indicates the length of the frame's payload section. The most significant byte is sent/received first.</td>
</tr>
<tr>
<td></td>
<td>• If the length/type field is set to a value less than 46, the payload is padded so that the minimum frame length requirement (64 bytes) is met. For VLAN-tagged frames, a value less than 42 indicates a padded frame.</td>
</tr>
<tr>
<td></td>
<td>• If the length/type field is set to a value larger than the programmed frame maximum length (e.g. 1518) it is interpreted as a type field.</td>
</tr>
<tr>
<td>Destination and source address</td>
<td>48-bit MAC addresses. The least significant byte is sent/received first and the first two least significant bits of the MAC address distinguish MAC frames, as detailed in MAC address check.</td>
</tr>
</tbody>
</table>
Note

Although the IEEE specification defines a maximum frame length, the MAC core provides the flexibility to program any value for the frame maximum length.

41.7.1.1 Pause Frames

The receiving device generates a pause frame to indicate a congestion to the emitting device, which should stop sending data.

Pause frames are indicated by the length/type set to 0x8808. The two first bytes of a pause frame following the type, defines a 16-bit opcode field set to 0x0001 always. A 16-bit pause quanta is defined in the frame payload bytes 2 (P1) and 3 (P2) as defined in the following table. The P1 pause quanta byte is the most significant.

</tbody>
</table>

There is no payload length field found within a pause frame and a pause frame is always padded with 42 bytes (0x00).

If a pause frame with a pause value greater than zero (XOFF condition) is received, the MAC stops transmitting data as soon the current frame transfer is completed. The MAC stops transmitting data for the value defined in pause quanta. One pause quanta fraction refers to 512 bit times.

If a pause frame with a pause value of zero (XON condition) is received, the transmitter is allowed to send data immediately (see Full-duplex flow control operation for details).

41.7.1.2 Magic packets

A magic packet is a unicast, multicast, or broadcast packet, which carries a defined sequence in the payload section.
Magic packets are received and inspected only under specific conditions as described in Magic packet detection.

The defined sequence to decode a magic packet is formed with a synchronization stream which consists of six consecutive 0xFF bytes, and is followed by sequence of sixteen consecutive unicast MAC addresses of the node to be awakened.

This sequence can be located anywhere in the magic packet payload. The magic packet is formed with a standard Ethernet header, optional padding, and CRC.

### 41.7.2 IP and higher layers frame format

The following sections use the term datagram to describe the protocol specific data unit that is found within the payload section of its container entity.

For example, an IP datagram specifies the payload section of an Ethernet frame. A TCP datagram specifies the payload section within an IP datagram.

#### 41.7.2.1 Ethernet types

IP datagrams are carried in the payload section of an Ethernet frame. The Ethernet frame type/length field discriminates several datagram types.

The following table lists the types of interest:

<table>
<thead>
<tr>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x8100</td>
<td>VLAN-tagged frame. The actual type is found 4 octets later in the frame.</td>
</tr>
<tr>
<td>0x0800</td>
<td>IPv4</td>
</tr>
<tr>
<td>0x0806</td>
<td>ARP</td>
</tr>
<tr>
<td>0x86DD</td>
<td>IPv6</td>
</tr>
</tbody>
</table>

#### 41.7.2.2 IPv4 datagram format

The following figure shows the IP Version 4 (IPv4) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words. The first byte sent/received is the leftmost byte of the first word (in other words, version/IHL field).

The IP header can contain further options, which are always padded if necessary to guarantee the payload following the header is aligned to a 32-bit boundary.
The IP header is immediately followed by the payload, which can contain further protocol headers (for example, TCP or UDP, as indicated by the protocol field value). The complete IP datagram is transported in the payload section of an Ethernet frame.

Table 41-9. IPv4 header format

<table>
<thead>
<tr>

<td>Identifier of protocol that follows in the datagram.</td>
</tr>
<tr>
<td>Header checksum</td>
<td>Checksum of IP header. For computational purposes, this field's value is zero.</td>
</tr>
<tr>
<td>Source address</td>
<td>Source IP address.</td>
</tr>
<tr>
<td>Destination address</td>
<td>Destination IP address.</td>
</tr>
</tbody>
</table>

41.7.2.3 IPv6 datagram format

The following figure shows the IP version 6 (IPv6) header, which is located at the beginning of an IP datagram. It is organized in 32-bit words and has a fixed length of ten words (40 bytes). The next header field identifies the type of the header that follows the IPv6 header. It is defined similar to the protocol identifier within IPv4, with new definitions for identifying extension headers. These headers can be inserted between the IPv6 header and the protocol header, which will shift the protocol header accordingly. The accelerator currently only supports IPv6 without extension headers (in other words, the next header specifies TCP, UDP, or IMCP).
The first byte sent/received is the leftmost byte of the first word (in other words, version/traffic class fields).

![Figure 41-4. IPv6 header format](image)

<table>
<thead>
<tr>
<th>Field name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Version</td>
<td>4-bit IP version information. 0x6 for all IPv6 frames.</td>
</tr>
<tr>
<td>Traffic class</td>
<td>8-bit field defining the traffic class.</td>
</tr>
<tr>

<td>20-bit flow label identifying frames of the same flow.</td>
</tr>
<tr>
<td>Payload length</td>
<td>16-bit length of the datagram payload in bytes. It includes all octets following the IPv6 header.</td>
</tr>
<tr>
<td>Next header</td>
<td>Identifies the header that follows the IPv6 header. This can be the protocol header or any IPv6 defined extension header.</td>
</tr>
<tr>
<td>Hop limit</td>
<td>Hop counter, decremented by one by each station that forwards the frame. If hop limit is 0 the frame must be discarded.</td>
</tr>
<tr>
<td>Source address</td>
<td>128-bit IPv6 source address.</td>
</tr>
<tr>
<td>Destination address</td>
<td>128-bit IPv6 destination address.</td>
</tr>
</tbody>
</table>

### 41.7.2.4 Internet Control Message Protocol (ICMP) datagram format

An internet control message protocol (ICMP) is found following the IP header, if the protocol identifier is 1. The ICMP datagram has a four-octet header followed by additional message data.

![Table 41-12. ICMP header format](image)
Table 41-13. IP header fields

<td>Code</td>
<td>8-bit code that is related to the message type</td>
</tr>
<tr>
<td>Checksum</td>
<td>16-bit one's complement checksum over the complete ICMP datagram</td>
</tr>
</tbody>
</table>

41.7.2.5 User Datagram Protocol (UDP) datagram format

A user datagram protocol header is found after the IP header, when the protocol identifier is 17.

The payload of the datagram is after the UDP header. The header byte order follows the conventions given for the IP header above.

Table 41-14. UDP header format

## 41.7.3 IEEE 1588 message formats

The following sections describe the IEEE 1588 message formats.

### 41.7.3.1 Transport encapsulation

The precision time protocol (PTP) datagrams are encapsulated in Ethernet frames using the UDP/IP transport mechanism, or optionally, with the newer 1588v2 directly in Ethernet frames (layer 2).

Typically, multicast addresses are used to allow efficient distribution of the synchronization messages.

#### 41.7.3.1.1 UDP/IP

The 1588 messages (v1 and v2) can be transported using UDP/IP multicast messages.
Table 41-18 shows IP multicast groups defined for PTP. The table also shows their respective MAC layer multicast address mapping according to RFC 1112 (last three octets of IP follow the fixed value of 01-00-5E).

<table>
<thead>
<tr>
<th>Name</th>
<th>IP Address</th>
<th>MAC Address mapping</th>
</tr>
</thead>
<tbody>
<tr>
<td>DefaultPTPdomain</td>
<td>224.0.1.129</td>
<td>01-00-5E-00-01-81</td>
</tr>
<tr>
<td>AlternatePTPdomain1</td>
<td>224.0.1.130</td>
<td>01-00-5E-00-01-82</td>
</tr>
<tr>
<td>AlternatePTPdomain2</td>
<td>224.0.1.131</td>
<td>01-00-5E-00-01-83</td>
</tr>
<tr>
<td>AlternatePTPdomain3</td>
<td>224.0.1.132</td>
<td>01-00-5E-00-01-84</td>
</tr>
</tbody>
</table>

Table 41-19. UDP port numbers

<table>
<thead>
<tr>
<th>Message type</th>
<th>UDP port</th>
<th>Note</th>
</tr>
</thead>
<tbody>
<tr>
<td>Event</td>
<td>319</td>
<td>Used for SYNC and DELAY_REQUEST messages</td>
</tr>
<tr>
<td>General</td>
<td>320</td>
<td>All other messages (for example, follow-up, delay-response)</td>
</tr>
</tbody>
</table>

41.7.3.1.2 Native Ethernet (PTPv2)

In addition to using UDP/IP frames, IEEE 1588v2 defines a native Ethernet frame format that uses ethertype = 0x88F7. The payload of the Ethernet frame immediately contains the PTP datagram, starting with the PTPv2 header.

Besides others, version 2 adds a peer delay mechanism to allow delay measurements between individual point-to-point links along a path over multiple nodes. The following multicast domains are also defined in PTPv2.

<table>
<thead>
<tr>
<th>Name</th>
<th>MAC address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Normal messages</td>
<td>01-1B-19-00-00-00</td>
</tr>
<tr>
<td>Peer delay messages</td>
<td>01-80-C2-00-00-0E</td>
</tr>
</tbody>
</table>

41.7.3.2 PTP header

All PTP frames contain a common header that determines the protocol version and the type of message, which defines the remaining content of the message.

All multi-octet fields are transmitted in big-endian order (the most significant byte is transmitted/received first).
The last four bits of versionPTP are at the same position (second byte) for PTPv1 and PTPv2 headers. This allows accurate identification by inspecting the first two bytes of the message.

### 41.7.3.2.1 PTPv1 header

Table 41-21. Common PTPv1 message header

<table>
<thead>
<tr>
<th>Offset</th>
<th>Octets</th>
<th>Bits</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>2</td>
<td>versionPTP = 0x0001</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>versionNetwork</td>
</tr>
<tr>
<td>4</td>
<td>16</td>
<td>subdomain</td>
</tr>
<tr>
<td>20</td>
<td>1</td>
<td>messageType</td>

</tr>
<tr>
<td>34</td>
<td>2</td>
<td>flags</td>
</tr>
<tr>
<td>36</td>
<td>4</td>
<td>reserved</td>
</tr>
</tbody>
</table>

The type of message is encoded in the messageType and control fields as shown in Table 41-22:

Table 41-22. PTPv1 message type identification

<table>
<thead>
<tr>
<th>messageType</th>
<th>control</th>
<th>Message Name</th>
<th>Message</th>
</tr>
</thead>
<tbody>
<tr>
<td>0x01</td>
<td>0x0</td>
<td>SYNC</td>

</tbody>
</table>

### 41.7.4 MAC receive

The MAC receive engine performs the following tasks:

- Check frame framing
- Remove frame preamble and frame SFD field
- Discard frame based on frame destination address field
- Terminate pause frames
- Check frame length
- Remove payload padding if it exists
- Calculate and verify CRC-32
- Write received frames in the core receive FIFO

If the MAC is programmed to operate in half-duplex mode, it will also check if the frame is received with a collision.
41.7.4.1 Collision detection in half-duplex mode

If the packet is received with a collision detected during reception of the first 64 bytes, the packet is discarded (if frame size was less than ~14 octets) or transmitted to the user application with an error and RxBD[CE] set.

41.7.4.2 Preamble processing

The IEEE 802.3 standard allows a maximum size of 56 bits (seven bytes) for the preamble, while the MAC core allows any preamble length, including zero length preamble.

The MAC core checks for the start frame delimiter (SFD) byte. If the next byte of the preamble, which is different from 0x55, is not 0xD5, the frame is discarded.

Although the IEEE specification dictates that the inner-packet gap should be at least 96 bits, the MAC core is designed to accept frames separated by only 64 10/100-Mbit/s operation (MII) bits.

The MAC core removes the preamble and SFD bytes.
41.7.4.3 MAC address check

The destination address bit 0 differentiates between multicast and unicast addresses.

- If bit 0 is 0, the MAC address is an individual (unicast) address.
- If bit 0 is 1, the MAC address defines a group (multicast) address.
- If all 48 bits of the MAC address are set, it indicates a broadcast address.

41.7.4.3.1 Unicast address check

If a unicast address is received, the destination MAC address is compared to the node MAC address programmed by the host in the PADDR1/2 registers.

If the destination address matches any of the programmed MAC addresses, the frame is accepted.

If Promiscuous mode is enabled (RCR[PROM] = 1) no address checking is performed and all unicast frames are accepted.

41.7.4.3.2 Multicast and unicast address resolution

The hash table algorithm used in the group and individual hash filtering operates as follows.

- The 48-bit destination address is mapped into one of 64 bits, represented by 64 bits in ENETn_GAUR/GALR (group address hash match) or ENETn_IAUR/IALR (individual address hash match).
- This mapping is performed by passing the 48-bit address through the on-chip 32-bit CRC generator and selecting the six most significant bits of the CRC-encoded result to generate a number between 0 and 63.
- The msb of the CRC result selects ENETn_GAUR (msb = 1) or ENETn_GALR (msb = 0).
- The five lsbs of the hash result select the bit within the selected register.
- If the CRC generator selects a bit set in the hash table, the frame is accepted; else, it is rejected.

For example, if eight group addresses are stored in the hash table and random group addresses are received, the hash table prevents roughly 56/64 (or 87.5%) of the group address frames from reaching memory. Those that do reach memory must be further filtered by the processor to determine if they truly contain one of the eight desired addresses.
The effectiveness of the hash table declines as the number of addresses increases.

The user must initialize the hash table registers. Use this CRC32 polynomial to compute the hash:

- FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1

If Promiscuous mode is enabled (ENETn_RCR[PROM] = 1) all unicast and multicast frames are accepted regardless of ENETn_GAUR/GALR and ENETn_IAUR/IALR settings.

### 41.7.4.3.3 Broadcast address reject

All broadcast frames are accepted if BC_REJ is cleared or ENETn_RCR[PROM] is set. If PROM is cleared when ENETn_RCR[BC_REJ] is set, all broadcast frames are rejected.

**Table 41-26. Broadcast address reject programming**

<table>
<thead>
<tr>
<th>PROM</th>
<th>BC_REJ</th>
<th>Broadcast frames</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>

<td>Rejected</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Accepted</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Accepted</td>
</tr>
</tbody>
</table>

### 41.7.4.3.4 Miss-bit implementation

For higher layer filtering purposes, RxBD[M] indicates an address miss when the MAC operates in promiscuous mode and accepts a frame that would otherwise be rejected.

If a group/individual hash or exact match does not occur and Promiscuous mode is enabled (RCR[PROM] = 1), the frame is accepted and the M bit is set in the buffer descriptor; otherwise, the frame is rejected.

This means the status bit is set in any of the following conditions during Promiscuous mode:

- A broadcast frame is received when BC_REJ is set
- A unicast is received that does not match either:
• Node address (PALR[PADDR1] and PAUR[PADDR2])
• Hash table for unicast (IAUR[IADDR1] and IALR[IADDR2])
• A multicast is received that does not match the GAUR[GADDR1] and GALR[GADDR2] hash table entries

41.7.4.4 Frame length/type verification: payload length check

If the length/type is less than 0x600 and NLC is set, the MAC checks the payload length and reports any error in the frame status word and interrupt bit PLR.

If the length/type is greater than or equal to 0x600, the MAC interprets the field as a type and no payload length check is performed.

The length check is performed on VLAN and stacked VLAN frames. If a padded frame is received, no length check can be performed due to the extended frame payload because padded frames can never have a payload length error.

41.7.4.5 Frame length/type verification: frame length check

When the receive frame length exceeds MAX_FL bytes, the BABR interrupt is generated and the RxBD[LG] bit is set.

The frame is not truncated unless the frame length exceeds the value programmed in ENETn_FTRL[TRUNC_FL]. If the frame is truncated, RxBD[TR] is set. In addition, a truncated frame always has the CRC error indication set (RxBD[CR]).

41.7.4.6 VLAN frames processing

VLAN frames have a length/type field set to 0x8100 immediately followed by a 16-Bit VLAN control information field.

VLAN-tagged frames are received as normal frames because the VLAN tag is not interpreted by the MAC function, and are pushed complete with the VLAN tag to the user application. If the length/type field of the VLAN-tagged frame, which is found four octets later in the frame, is less than 42, the padding is removed. In addition, the frame status word (RxBD[NO]) indicates that the current frame is VLAN tagged.
41.7.4.7 Pause frame termination

The receive engine terminates pause frames and does not transfer them to the receive FIFO. The quanta is extracted and sent to the MAC transmit path via a small internal clock rate decoupling asynchronous FIFO.

The quanta is written only if a correct CRC and frame length are detected by the control state machine. If not, the quanta is discarded and the MAC transmit path is not paused.

Good pause frames are ignored if ENETn_RCR[FCE] is cleared and are forwarded to the client interface when ENETn_RCR[PAUFWD] is set.

41.7.4.8 CRC check

The CRC-32 field is checked and forwarded to the core FIFO interface if ENETn_RCR[CRCFWD] is cleared and ENETn_RCR[PADEN] is cleared. When CRCFWD is set (regardless of PADEN), the CRC-32 field is checked and terminated (not transmitted to the FIFO).

The CRC polynomial, as specified in the 802.3 standard, is:

- FCS(x) = x^{32} + x^{26} + x^{23} + x^{22} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1

The 32 bits of the CRC value are placed in the frame check sequence (FCS) field with the $x^{31}$ term as right-most bit of the first octet. The CRC bits are thus received in the following order: $x^{31}$, $x^{30}$, ..., $x^{1}$, $x^{0}$.

If a CRC error is detected, the frame is marked invalid and RxBD[CR] is set.

41.7.4.9 Frame padding removal

When a frame is received with a payload length field set to less than 46 (42 for VLAN-tagged frames and 38 for frames with stacked VLANs), the zero padding can be removed before the frame is written into the data FIFO depending on the setting of ENETn_RCR[PADEN].

Note

If a frame is received with excess padding (in other words, the length field is set as mentioned above, but the frame has more than 64 octets) and padding removal is enabled, then the
padding is removed as normal and no error is reported if the frame is otherwise correct (for example: good CRC, less than maximum length, and no other error).

41.7.5 MAC transmit

Frame transmission starts when the transmit FIFO holds enough data.

After a transfer starts, the MAC transmit function performs the following tasks:

- Generates preamble and SFD field before frame transmission
- Generates XOFF pause frames if the receive FIFO reports a congestion or if ENETn_TCR[TFC_PAUSE] is set with ENETn_OPD[PAUSE_DUR] set to a non-zero value
- Generates XON pause frames if the receive FIFO congestion condition is cleared or if TFC_PAUSE is set with PAUSE_DUR cleared
- Suspends Ethernet frame transfer (XOFF) if a non-zero pause quanta is received from the MAC receive path
- Adds padding to the frame if required
- Calculates and appends CRC-32 to the transmitted frame
- Sends the frame with correct inter-packet gap (IPG) (deferring)

When the MAC is configured to operate in half-duplex mode, the following additional tasks are performed:

- Collision detection
- Frame retransmit after back-off timer expires
41.7.5.1 Frame payload padding

The IEEE specification defines a minimum frame length of 64 bytes.

If the frame sent to the MAC from the user application has a size smaller than 60 bytes, the MAC automatically adds padding bytes (0x00) to comply with the Ethernet minimum frame length specification. Transmit padding is always performed and cannot be disabled.

If the MAC is not allowed to append a CRC (TxBD[TC] = 1), the user application is responsible for providing frames with a minimum length of 64 octets.

41.7.5.2 MAC address insertion

On each frame received from the core transmit FIFO interface, the source MAC address is either:

- Replaced by the address programmed in the PADDR1/2 fields (ENETn_TCR[ADDINS] = 1)
- Transparently forwarded to the Ethernet line (ENETn_TCR[ADDINS] = 0)

41.7.5.3 CRC-32 generation

The CRC-32 field is optionally generated and appended at the end of a frame.
The CRC polynomial, as specified in the 802.3 standard, is:

- \( FCS(x) = x^{32} + x^{26} + x^{23} + x^{16} + x^{12} + x^{11} + x^{10} + x^{8} + x^{7} + x^{5} + x^{4} + x^{2} + x^{1} + 1 \)

The 32 bits of the CRC value are placed in the FCS field so that the \( x^{31} \) term is the rightmost bit of the first octet. The CRC bits are thus transmitted in the following order: \( x^{31}, x^{30}, ..., x^1, x^0 \).

### 41.7.5.4 Inter-packet gap (IPG)

In full-duplex mode, after frame transmission and before transmission of a new frame, an IPG (programmed in ENETn_TIPG) is maintained. The minimum IPG can be programmed between 8 and 26 byte-times (64 and 208 bit-times).

In half-duplex mode, the core constantly monitors the line. Actual transmission of the data onto the network occurs only if it has been idle for a 96-bit time period, and any back-off time requirements have been satisfied. In accordance with the standard, the core begins to measure the IPG from CRS de-assertion.

### 41.7.5.5 Collision detection and handling — half-duplex operation only

A collision occurs on a half-duplex network when concurrent transmissions from two or more nodes take place. During transmission, the core monitors the line condition and detects a collision when the PHY device asserts COL.

When the core detects a collision while transmitting, it stops transmission of the data and transmits a 32-bit jam pattern. If the collision is detected during the preamble or the SFD transmission, the jam pattern is transmitted after completing the SFD, which results in a minimum 96-bit fragment. The jam pattern is a fixed pattern that is not compared to the actual frame CRC, and has a very low probability (0.532) of having a jam pattern identical to the CRC.

If a collision occurs before transmission of 64 bytes (including preamble and SFD), the MAC core waits for the backoff period and retransmits the packet data (stored in a 64-byte re-transmit buffer) that has already been sent on the line. The backoff period is generated from a pseudo-random process (truncated binary exponential backoff).

If a collision occurs after transmission of 64 bytes (including preamble and SFD), the MAC discards the remainder of the frame, optionally sets the LC interrupt bit, and sets TxBD[LCE].
Figure 41-7. Packet re-transmit overview

The backoff time is represented by an integer multiple of slot times. One slot is equal to a 512-bit time period. The number of the delay slot times, before the \(n\)th re-transmission attempt, is chosen as a uniformly-distributed random integer in the range:

- \(0 < r < 2^k\)
- \(k = \min(n, N)\); where \(n\) is the number of retransmissions and \(N = 10\)

For example, after the first collision, the backoff period is 0 or 1 slot time. If a collision occurs on the first retransmission, the backoff period is 0, 1, 2, or 3, and so on.

The maximum backoff time (in 512-bit time slots) is limited by \(N = 10\) as specified in the IEEE 802.3 standard.

If a collision occurs after 16 consecutive retransmissions, the core reports an excessive collision condition (ENET\(n\)_EIR[RL] interrupt field and TxBD[EE]) and discards the current packet from the FIFO.

In networks violating the standard requirements, a collision may occur after transmission of the first 64 bytes. In this case, the core stops the current packet transmission and discards the rest of the packet from the transmit FIFO. The core resumes transmission with the next packet available in the core transmit FIFO.

**warning**

Ethernet PHYs that support the SQE Test, or "heartbeat," feature must disable this feature. When this feature is enabled,
the PHY asserts the collision signal after a frame is transmitted to indicate to the ENET that the PHY's collision logic is working. This may cause data corruption in the next frame from the ENET. This corrupted frame contains up to 21 zero bytes which start somewhere within the MAC destination address field. The ENET, however, will still generate a good FCS (CRC-32) but with corrupted data.

41.7.6 Full-duplex flow control operation

Three conditions are handled by the core's flow control engine:

- Remote device congestion — The remote device connected to the same Ethernet segment as the core reports congestion and requests that the core stop sending data.

- Core FIFO congestion — When the core's receive FIFO reaches a user-programmable threshold (RX section empty), the core sends a pause frame back to the remote device requesting the data transfer to stop.

- Local device congestion — Any device connected to the core can request (typically, via the host processor) the remote device to stop transmitting data.

41.7.6.1 Remote device congestion

When the MAC transmit control gets a valid pause quanta from the receive path and if ENETn_RCR[FCE] is set, the MAC transmit logic:

- Completes the transfer of the current frame.

- Stops sending data for the amount of time specified by the pause quanta in 512 bit time increments.

- Sets ENETn_TCR[RFC_PAUSE].

Frame transfer resumes when the time specified by the quanta expires and if no new quanta value is received, or if a new pause frame with a quanta value set to 0x0000 is received. The MAC also resets RFC_PAUSE to zero.

If ENETn_RCR[FCE] cleared, the MAC ignores received pause frames.

Optionally and independent of ENETn_RCR[FCE], pause frames are forwarded to the client interface if PAUFWD is set.
41.7.6.2 Local device/FIFO congestion

The MAC transmit engine generates pause frames when the local receive FIFO is not able to receive more than a pre-defined number of words (FIFO programmable threshold) or when pause frame generation is requested by the local host processor.

- To generate a pause frame, the host processor sets ENETn_TCR[TFC_PAUSE]. A single pause frame is generated when the current frame transfer is completed and TFC_PAUSE is automatically cleared. Optionally, an interrupt is generated.

- An XOFF pause frame is generated when the receive FIFO asserts its section empty flag (internal). An XOFF pause frame is generated automatically, when the current frame transfer completes.

- An XON pause frame is generated when the receive FIFO deasserts its section empty flag (internal). An XON pause frame is generated automatically, when the current frame transfer completes.

When an XOFF pause frame is generated, the pause quanta (payload byte P1 and P2) is filled with the value programmed in ENETn_OPD[PAUSE_DUR].

![Figure 41-8. Pause frame generation overview](image)

**Note**

Although the flow control mechanism should prevent any FIFO overflow on the MAC core receive path, the core receive FIFO is protected. When an overflow is detected on the receive FIFO, the current frame is truncated with an error indication set in the frame status word. The frame should subsequently be discarded by the user application.
41.7.7  Magic packet detection

Magic packet detection wakes a node that is put in power-down mode by the node management agent. Magic packet detection is supported only if the MAC is configured in sleep mode.

41.7.7.1  Sleep mode

To put the MAC in Sleep mode, set ENETn_ECR[SLEEP]. At the same time ENETn_ECR[MAGICEN] should also be set to enable magic packet detection.

In addition, if ENET is enabled, write 1 to ENETn_ECR[SLEEP] before entering into low power mode.

When the MAC is in Sleep mode:

- The transmit logic is disabled.
- The FIFO receive/transmit functions are disabled.
- The receive logic is kept in Normal mode, but it ignores all traffic from the line except magic packets. They are detected so that a remote agent can wake the node.

41.7.7.2  Magic packet detection

The core is designed to detect magic packets (see Magic packets) with the destination address set to:

- Any multicast address
- The broadcast address
- The unicast address programmed in PADDR1/2

When a magic packet is detected, EIR[WAKEUP] is set and none of the statistic registers are incremented.
41.7.7.3  Wakeup

When a magic packet is detected, indicated by ENETₙ_EIR[WAKEUP], ENETₙ_ECR[SLEEP] should be cleared to resume normal operation of the MAC. Clearing the SLEEP bit automatically masks ENETₙ_ECR[MAGICEN], disabling magic packet detection.

41.7.8  IP accelerator functions

The following sections describe the IP accelerator functions.

41.7.8.1  Checksum calculation

The IP and ICMP, TCP, UDP checksums are calculated with one's complement arithmetic summing up 16-bit values.

- For ICMP, the checksum is calculated over the complete ICMP datagram, in other words without IP header.
- For TCP and UDP, the checksums contain the header and data sections and values from the IP header, which can be seen as a pseudo-header that is not actually present in the data stream.

</table>
The TCP/UDP length value is the length of the TCP or UDP datagram, which is equal to the payload of an IP datagram. It is derived by subtracting the IP header length from the complete IP datagram length that is given in the IP header (IPv4), or directly taken from the IP header (IPv6). The protocol field is the corresponding value from the IP header. The Zero fields are all zeroes.

For IPv6, the complete 128-bit addresses are considered. The next header value identifies the upper layer protocol as either TCP or UDP. It may differ from the next header value of the IPv6 header if extension headers are inserted before the protocol header.

The checksum calculation uses 16-bit words in network byte order: The first byte sent/received is the MSB, and the second byte sent/received is the LSB of the 16-bit value to add to the checksum. If the frame ends on an odd number of bytes, a zero byte is appended for checksum calculation only, and is not actually transmitted.

### 41.7.8.2 Additional padding processing

According to IEEE 802.3, any Ethernet frame must have a minimum length of 64 octets.

The MAC usually removes padding on receive when a frame with length information is received. Because IP frames have a type value instead of length, the MAC does not remove padding for short IP frames, as it is not aware of the frame contents.

The IP accelerator function can be configured to remove the Ethernet padding bytes that might follow the IP datagram.

On transmit, the MAC automatically adds padding as necessary to fill any frame to a 64-byte length.

### 41.7.8.3 32-bit Ethernet payload alignment

The data FIFOs allow inserting two additional arbitrary bytes in front of a frame. This extends the 14-byte Ethernet header to a 16-byte header, which leads to alignment of the Ethernet payload, following the Ethernet header, on a 32-bit boundary.

This function can be enabled for transmit and receive independently with the corresponding SHIFT16 bits in the ENETn_TACC and ENETn_RACC registers.

When enabled, the valid frame data is arranged as shown in Table 41-29.

| Table 41-29. 64-bit interface data structure with SHIFT16 enabled |
|----------------|----------------|----------------|----------------|----------------|----------------|----------------|
| 63 56          | 55 48          | 47 40          | 39 32          | 31 24          | 23 16          | 15 8           | 7 0            |

*Table continues on the next page...*
### 41.7.8.3.1 Receive processing

When ENET\textsubscript{n} RACC[SHIFT16] is set, each frame is received with two additional bytes in front of the frame.

The user application must ignore these first two bytes and find the first byte of the frame in bits 23–16 of the first word from the RX FIFO.

**Note**

SHIFT16 must be set during initialization and kept set during the complete operation, because it influences the FIFO write behavior.

### 41.7.8.3.2 Transmit processing

When ENET\textsubscript{n} TACC[SHIFT16] is set, the first two bytes of the first word written (bits 15–0) are discarded immediately by the FIFO write logic.

The SHIFT16 bit can be enabled/disabled for each frame individually if required, but can be changed only between frames.

### 41.7.8.4 Received frame discard

Because the receive FIFO must be operated in store and forward mode (ENET\textsubscript{n} RSFL cleared), received frames can be discarded based on the following errors:

- The MAC function receives the frame with an error:
  - The frame has an invalid payload length
  - Frame length is greater than MAX\_FL
  - Frame received with a CRC-32 error
  - Frame truncated due to receive FIFO overflow
  - Frame is corrupted as PHY signaled an error (RX\_ERR asserted during reception)
• An IP frame is detected and the IP header checksum is wrong

• An IP frame with a valid IP header and a valid IP header checksum is detected, the protocol is known but the protocol-specific checksum is wrong

If one of the errors occurs and the IP accelerator function is configured to discard frames (ENETn_RACC), the frame is automatically discarded. Statistics are maintained normally and are not affected by this discard function.

### 41.7.8.5 IPv4 fragments

When an IPv4 IP fragment frame is received, only the IP header is inspected and its checksum verified. 32-bit alignment operates the same way on fragments as it does on normal IP frames, as specified above.

The IP fragment frame payload is not inspected for any protocol headers. As such, a protocol header would only exist in the very first fragment. To assist in protocol-specific checksum verification, the one's-complement sum is calculated on the IP payload (all bytes following the IP header) and provided with the frame status word.

The frame fragment status field (RxBD[FRAG]) is set to indicate a fragment reception, and the one's-complement sum of the IP payload is available in RxBD[Payload checksum].

**Note**

After all fragments have been received and reassembled, the application software can take advantage of the payload checksum delivered with the frame's status word to calculate the protocol-specific checksum of the datagram.

For example, if a TCP payload is delivered by multiple IP fragments, the application software can calculate the pseudo-header checksum value from the first fragment, and add the payload checksums delivered with the status for all fragments to verify the TCP datagram checksum.

### 41.7.8.6 IPv6 support

The following sections describe the IPv6 support.
41.7.8.6.1 Receive processing

An Ethernet frame of type 0x86DD identifies an IP Version 6 frame (IPv6) frame. If an IPv6 frame is received, the first IP header is inspected (first ten words), which is available in every IPv6 frame.

If the receive SHIFT16 function is enabled, the IP header is aligned on a 32-bit boundary allowing more efficient processing (see 32-bit Ethernet payload alignment).

For TCP and UDP datagrams, the pseudo-header checksum calculation is performed and verified.

To assist in protocol-specific checksum verification, the one's-complement sum is always calculated on the IP payload (all bytes following the IP header) and provided with the frame status word. For example, if extension headers were present, their sums can be subtracted in software from the checksum to isolate the TCP/UDP datagram checksum, if required.

41.7.8.6.2 Transmit processing

For IPv6 transmission, the SHIFT16 function is supported to process 32-bit aligned datagrams.

IPv6 has no IP header checksum; therefore, the IP checksum insertion configuration is ignored.

The protocol checksum is inserted only if the next header of the IP header is a known protocol (TCP, UDP, or ICMP). If a known protocol is detected, the checksum over all bytes following the IP header is calculated and inserted in the correct position.

The pseudo-header checksum calculation is performed for TCP and UDP datagrams accordingly.

41.7.9 Resets and stop controls

The following sections describe the resets and stop controls.

41.7.9.1 Hardware reset

To reset the Ethernet module, set ENETn_ECR[RESET].

41.7.9.2 Soft reset

When ENET\(_n\)_ECR[ETHER_EN] is cleared during operation, the following occurs:

- uDMA, buffer descriptor, and FIFO control logic are reset, including the buffer descriptor and FIFO pointers.
- A currently ongoing transmit is terminated by asserting TXER to the PHY.
- A currently ongoing transmit FIFO write from the application is terminated by stopping the write to the FIFO, and all further data from the application is ignored. All subsequent writes are ignored until re-enabled.
- A currently ongoing receive FIFO read is terminated. The RxBD has arbitrary values in this case.

41.7.9.3 Hardware freeze

When the processor enters debug mode and ECR[DBGEN] is set, the MAC enters a freeze state where it stops all transmit and receive activities gracefully.

The following happens when the MAC enters hardware freeze:

- A currently ongoing receive transaction on the receive application interface is completed as normal. No further frames are read from the FIFO.
- A currently ongoing transmit transaction on the transmit application interface is completed as normal (in other words, until writing end-of-packet (EOP)).
- A currently ongoing frame receive is completed normally, after which no further frames are accepted from the MII.
- A currently ongoing frame transmit is completed normally, after which no further frames are transmitted.

41.7.9.4 Graceful stop

During a graceful stop, any currently ongoing transactions are completed normally and no further frames are accepted. The MAC can resume from a graceful stop without the need for a reset (for example, clearing ETHER_EN is not required).

The following conditions lead to a graceful stop of the MAC transmit or receive datapaths.
41.7.9.4.1 Graceful transmit stop (GTS)

When gracefully stopped, the MAC is no longer reading frame data from the transmit FIFO and has completed any ongoing transmission.

In any of the following conditions, the transmit datapath stops after an ongoing frame transmission has been completed normally.

- ENETn_TCR[GTS] is set by software.
- ENETn_TCR[TFC_PAUSE] is set by software requesting a pause frame transmission. The status (and register bit) is cleared after the pause frame has been sent.
- A pause frame was received stopping the transmitter. The stopped situation is terminated when the pause timer expires or a pause frame with zero quanta is received.
- MAC is placed in Sleep mode by software or the processor entering Stop mode (see Sleep mode).
- The MAC is in Hardware Freeze mode.

When the transmitter has reached its stopped state, the following events occur:

- The GRA interrupt is asserted, when transitioned into stopped.
- In Hardware Freeze mode, the GRA interrupt does not wait for the application write completion and asserts when the transmit state machine (in other words, line side of TX FIFO) reaches its stopped state.

41.7.9.4.2 Graceful receive stop (GRS)

When gracefully stopped, the MAC is no longer writing frames into the receive FIFO.

The receive datapath stops after any ongoing frame reception has been completed normally, if any of the following conditions occur:

- MAC is placed in Sleep mode either by the software or the processor is in Stop mode). The MAC continues to receive frames and search for magic packets if enabled (see Magic packet detection). However, no frames are written into the receive FIFO, and therefore are not forwarded to the application.
- The MAC is in Hardware Freeze mode. The MAC does not accept any frames from the MII.
When the receive datapath is stopped, the following events occur:

- If the RX is in the stopped state, RCR[GRS] is set
- The GRA interrupt is asserted when the transmitter and receiver are stopped
- Any ongoing receive transaction to the application (RX FIFO read) continues normally until the frame end of package (EOP) is reached. After this, the following occurs:
  - When Sleep mode is active, all further frames are discarded, flushing the RX FIFO
  - In Hardware Freeze mode, no further frames are delivered to the application and they stay in the receive FIFO.

**Note**

The assertion of GRS does not wait for an ongoing FIFO read transaction on the application side of the FIFO (FIFO read).

### 41.7.9.4.3 Graceful stop interrupt (GRA)

The graceful stopped interrupt (GRA) is asserted for the following conditions:

- In Sleep mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- In Hardware Freeze mode, the interrupt asserts only after both TX and RX datapaths are stopped.
- The MAC transmit datapath is stopped for any other condition (GTS, TFC_PAUSE, pause received).

The GRA interrupt is triggered only once when the stopped state is entered. If the interrupt is cleared while the stop condition persists, no further interrupt is triggered.
41.7.10 IEEE 1588 functions

To allow for IEEE 1588 or similar time synchronization protocol implementations, the MAC is combined with a time-stamping module to support precise time-stamping of incoming and outgoing frames. Set ENET\textsubscript{n}_ECR[EN1588] to enable 1588 support.

![Figure 41-9. IEEE 1588 functions overview](image)

41.7.10.1 Adjustable timer module

The adjustable timer module (TSM) implements the free-running counter (FRC), which generates the timestamps. The FRC operates with the time-stamping clock, which can be set to any value depending on your system requirements.

Through dedicated correction logic, the timer can be adjusted to allow synchronization to a remote master and provide a synchronized timing reference to the local system. The timer can be configured to cause an interrupt after a fixed time period, to allow synchronization of software timers or perform other synchronized system functions.

The timer is typically used to implement a period of one second; hence, its value ranges from 0 to \((1 \times 10^9)-1\). The period event can trigger an interrupt, and software can maintain the seconds and hours time values as necessary.

41.7.10.1.1 Adjustable timer implementation

The adjustable timer consists of a programmable counter/accumulator and a correction counter. The periods of both counters and their increment rates are freely configurable, allowing very fine tuning of the timer.
See Timer Synchronization for Multi-Port Implementations, for external clock input options.

The counter produces the current time. During each time-stamping clock cycle, a constant value is added to the current time as programmed in ENETn_ATINC. The value depends on the chosen time-stamping clock frequency. For example, if it operates at 125 MHz, setting the increment to eight represents 8 ns.

The period, configured in ENETn_ATPER, defines the modulo when the counter wraps. In a typical implementation, the period is set to $1 \times 10^9$ so that the counter wraps every second, and hence all timestamps represent the absolute nanoseconds within the one second period. When the period is reached, the counter wraps to start again respecting the period modulo. This means it does not necessarily start from zero, but instead the counter is loaded with the value $(\text{Current} + \text{Inc} - (1 \times 10^9))$, assuming the period is set to $1 \times 10^9$.

The correction counter operates fully independently, and increments by one with each time-stamping clock cycle. When it reaches the value configured in ENETn_ATCOR, it restarts and instructs the timer once to increment by the correction value, instead of the normal value.

The normal and correction increments are configured in ENETn_ATINC. To speed up the timer, set the correction increment more than the normal increment value. To slow down the timer, set the correction increment less than the normal increment value.

The correction counter only defines the distance of the corrective actions, not the amount. This allows very fine corrections and low jitter (in the range of 1 ns) independent of the chosen clock frequency.
By enabling slave mode (ENET\textsubscript{n} ATCR[SLAVE] = 1), the timer is ignored and the current time is externally provided from one of the external modules. See the Chip Configuration details for which clock source is used. This is useful if multiple modules within the system must operate from a single timer (see Timer Synchronization for Multi-Port Implementations). When slave mode is enabled, you still must set ENET\textsubscript{n} ATINC[INC] to the value of the master, since it is used for internal comparisons.

### 41.7.10.2 Timer Synchronization for Multi-Port Implementations

Additional inputs are available to provide a timer value for all time-stamping functions. This is necessary to synchronize the two MACs to a single reference timer. See the Chip Configuration details for available clock inputs to the time-stamping functions. To operate the MAC in slave mode, ENET\textsubscript{n} ATCR[SLAVE] disables the internal adjustable timer and uses the externally provided timer.

### 41.7.10.3 Transmit timestamping

Only 1588 event frames need to be time-stamped on transmit. The client application (for example, the MAC driver) should detect 1588 event frames and set TxBD[TS] together with the frame.

If TxBD[TS] is set, the MAC records the timestamp for the frame in ENET\textsubscript{n} ATSTMP. ENET\textsubscript{n} EIR[TS_AVAIL] is set to indicate that a new timestamp is available.

Software implements a handshaking procedure by setting TxBD[TS] when it transmits the frame for which a timestamp is needed, and then waits for ENET\textsubscript{n} EIR[TS_AVAIL] to determine when the timestamp is available. The timestamp is then read from ENET\textsubscript{n} ATSTMP. This is done for all event frames. Other frames do not use TxBD[TS] and, therefore, do not interfere with the timestamp capture.

### 41.7.10.4 Receive timestamping

When a frame is received, the MAC latches the value of the timer when the frame's start of frame delimiter (SFD) field is detected, and provides the captured timestamp on RxBD[1588 timestamp]. This is done for all received frames.
41.7.10.5 Time synchronization

The adjustable timer module is available to synchronize the local clock of a node to a remote master. It implements a free running 32-bit counter, and also contains an additional correction counter.

The correction counter increases or decreases the rate of the free running counter, enabling very fine granular changes of the timer for synchronization, yet adding only very low jitter when performing corrections.

The application software implements, in a slave scenario, the required control algorithm, setting the correction to compensate for local oscillator drifts and locking the timer to the remote master clock on the network.

The timer and all timestamp-related information should be configured to show the true nanoseconds value of a second (in other words, the timer is configured to have a period of one second). Hence, the values range from 0 to \((1 \times 10^9)–1\). In this application, the seconds counter is implemented in software using an interrupt function that is executed when the nanoseconds counter wraps at \(1 \times 10^9\).

41.7.10.6 Input Capture and Output Compare

The Input Capture Output Compare block can be used to provide precise hardware timing for input and output events.

41.7.10.6.1 Input capture

The TCCR\textsubscript{n} capture registers latch the time value when the corresponding external event occurs. An event can be a rising-, falling-, or either-edge of one of the 1588_TMR\textsubscript{n} signals. An event will cause the corresponding TCSR\textsubscript{n}[TF] timer flag to be set, indicating that an input capture has occurred. If the corresponding interrupt is enabled with the TCSR\textsubscript{n}[TIE] field, an interrupt can be generated.

41.7.10.6.2 Output compare

The TCCR\textsubscript{n} compare registers are loaded with the time at which the corresponding event should occur. When the ENET free-running counter value matches the output compare reference value in the TCCR\textsubscript{n} register, the corresponding flag, TCSR\textsubscript{n}[TF], is set, indicating that an output compare has occurred. The corresponding interrupt, if enabled by TCSR\textsubscript{n}[TIE], will be generated. The corresponding 1588_TMR\textsubscript{n} output signal will be asserted according to TCSR\textsubscript{n}[TMODE].
NOTE
If TSCR\textsubscript{n}[TMODE] is set to 10X1b or 1010b then the timer output pin toggle-on-overflow will occur only when PINPER, PEREN, and EN bits of the ATCR register are one.

41.7.10.6.3 DMA requests
A DMA request can be enabled by setting TCSR\textsubscript{n}[TDRE]. The corresponding DMA request is generated when the TCSR\textsubscript{n}[TF] timer flag is set. When the DMA has completed, the corresponding TCSR\textsubscript{n}[TF] flag is cleared.

41.7.11 FIFO thresholds
The core FIFO thresholds are fully programmable to dynamically change the FIFO operation.

For example, store and forward transfer can be enabled by a simple change in the FIFO threshold registers.

The thresholds are defined in 64-bit words.

The receive and transmit FIFOs both have a depth of 256 words.

41.7.11.1 Receive FIFO
Four programmable thresholds are available, which can be set to any value to control the core operation as follows.

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ENET\textsubscript{n}_RSFL [RX_SECTION_FULL]</td>
<td>When the FIFO level reaches the ENET\textsubscript{n}_RSFL value, the MAC status signal is asserted to indicate that data is available in the receive FIFO (cut-through operation). Once asserted, if the FIFO empties below the threshold set with ENET\textsubscript{n}_RAEM and if the end-of-frame is not yet stored in the FIFO, the status signal is deasserted again. If a frame has a size smaller than the threshold (in other words, an end-of-frame is available for the frame), the status is also asserted. To enable store and forward on the receive path, clear ENET\textsubscript{n}_RSFL. The MAC status signal is asserted only when a complete frame is stored in the receive FIFO. When programming a non-zero value to ENET\textsubscript{n}_RSFL (cut-through operation) it should be greater than ENET\textsubscript{n}_RAEM.</td>
</tr>
<tr>
<td>ENET\textsubscript{n}_RAEM</td>
<td>When the FIFO level reaches the ENET\textsubscript{n}_RAEM value, and the end-of-frame has not been received, the core receive read control stops the FIFO read (and subsequently stops transferring data to the MAC client application).</td>
</tr>
</tbody>
</table>

Table continues on the next page...
### Table 41-30. Receive FIFO thresholds definition (continued)

<td>[RX_ALMOSTEMPTY]</td>
<td>It continues to deliver the frame, if again more data than the threshold or the end-of-frame is available in the FIFO.</td>
</tr>
<tr>
<td></td>
<td>Set ENET_RAEM to a minimum of six.</td>
</tr>
<tr>
<td>ENET_RAFL</td>
<td>When the FIFO level approaches the maximum and there is no more space remaining for at least ENET_RAFL number of words, the MAC control logic stops writing data in the FIFO and truncates the receive frame to avoid FIFO overflow.</td>
</tr>
<tr>
<td>[RX_ALMOSTFULL]</td>
<td>The corresponding error status is set when the frame is delivered to the application.</td>
</tr>
<tr>
<td></td>
<td>Set ENET_RAFL to a minimum of 4.</td>
</tr>
<tr>
<td>ENET_RSEM</td>
<td>When the FIFO level reaches the ENET_RSEM value, an indication is sent to the MAC transmit logic, which generates an XOFF pause frame. This indicates FIFO congestion to the remote Ethernet client.</td>
</tr>
<tr>
<td>[RX_SECTIONEMPTY]</td>
<td>When the FIFO level goes below the value programmed in ENET_RSEM, an indication is sent to the MAC transmit logic, which generates an XON pause frame. This indicates the FIFO congestion is cleared to the remote Ethernet client.</td>
</tr>
<tr>
<td></td>
<td>Clearing ENET_RSEM disables any pause frame generation.</td>
</tr>
</tbody>
</table>

**Figure 41-11. Receive FIFO overview**

### 41.7.11.2 Transmit FIFO

Four programmable thresholds are available which control the core operation as described below.
### Table 41-31. Transmit FIFO thresholds definition

<table>
<thead>
<tr>
<th>Register</th>
<th>Description</th>
</tr>
</thead>
</table>
| ENET<sub>n</sub>TAEM [TX_ALMOST_EMPTY] | When the FIFO level reaches the ENET<sub>n</sub>TAEM value and no end-of-frame is available for the frame, the MAC transmit logic avoids a FIFO underflow by stopping FIFO reads and transmitting the Ethernet frame with an MII error indication.  
Set ENET<sub>n</sub>TAEM to a minimum of 4. |
| ENET<sub>n</sub>TAFL [TX_ALMOST_FULL] | When the FIFO level approaches the maximum, so that there is no more space for at least ENET<sub>n</sub>TAFL number of words, the MAC deasserts its control signal to the application.  
If the application does not react on this signal, the FIFO write control logic avoids FIFO overflow by truncating the current frame and setting the error status. As a result, the frame is transmitted with an MII error indication.  
Set ENET<sub>n</sub>TAFL to a minimum of 4. Larger values allow more latency for the application to react on the MAC control signal deassertion, before the frame is truncated. A typical setting is 8, which offers 3–4 clock cycles of latency to the application to react on the MAC control signal deassertion. |
| ENET<sub>n</sub>TSEM [TX_SECTION_EMPTY] | When the FIFO level reaches the ENET<sub>n</sub>TSEM value, a MAC status signal is deasserted to indicate that the transmit FIFO is getting full. This gives the ENET module an indication to slow or stop its write transaction to avoid a buffer overflow. This is a pure indication function to the application. It has no effect within the MAC.  
When ENET<sub>n</sub>TSEM is 0, the signal is never deasserted. |
| ENET<sub>n</sub>TFWR | When the FIFO level reaches the ENET<sub>n</sub>TFWR value and when STRFWD is cleared, the MAC transmit control logic starts frame transmission before the end-of-frame is available in the FIFO (cut-through operation).  
If a complete frame has a size smaller than the ENET<sub>n</sub>TFWR threshold, the MAC also transmits the frame to the line.  
To enable store and forward on the transmit path, set STRFWD. In this case, the MAC starts to transmit data only when a complete frame is stored in the transmit FIFO. |

1. This field is not supported by the uDMA.

41.7.14 Enhanced buffer descriptors

This section provides a description of the enhanced operation of the driver/uDMA via the buffer descriptors.

It is followed by a detailed description of the receive and transmit descriptor fields. To enable the enhanced features, set ENETn_ECR[1588EN].

NOTE

The enhanced buffer descriptor tables show the byte order for little-endian chips. DBSVP must be set to 1 after reset to enable little-endian mode.
### 41.7.14.1 Enhanced receive buffer descriptor

41.7.15 Client FIFO application interface

The FIFO interface is completely asynchronous from the Ethernet line, and the transmit and receive interface can operate at a different clock rate.

All transfers to/from the user application are handled independently of the core operation, and the core provides a simple interface to user applications based on a two-signal handshake.

41.7.15.1 Data structure description

The data structure defined in the following tables for the FIFO interface must be respected to ensure proper data transmission on the Ethernet line. Byte 0 is sent to and received from the line first.

<table>

</tr>
</tbody>
</table>

The size of a frame on the FIFO interface may not be a modulo of 64-bit.

The user application may not care about the Ethernet frame formats in full detail. It needs to provide and receive an Ethernet frame with the following structure:

- Ethernet MAC destination address
- Ethernet MAC source address
- Optional 802.1q VLAN tag (VLAN type and info field)
- Ethernet length/type field
- Payload

Frames on the FIFO interface do not contain preamble and SFD fields, which are inserted and discarded by the MAC on transmit and receive, respectively.
• On receive, CRC and frame padding can be stripped or passed through transparently.
• On transmit, padding and CRC can be provided by the user application, or appended automatically by the MAC independently for each frame. No size restrictions apply.

**Note**

On transmit, if ENET\_TCR[ADDINS] is set, bytes 6–11 of each frame can be set to any value, since the MAC overwrites the bytes with the MAC address programmed in the ENET\_PAUR and ENET\_PALR registers.

**Table 41-40. FIFO interface frame format**

<table>
<thead>
<tr>
<th>Byte number</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0–5</td>
<td>Destination MAC address</td>
</tr>
<tr>
<td>6–11</td>
<td>Source MAC address</td>
</tr>
<tr>
<td>12–13</td>
<td>Length/type field</td>
</tr>
<tr>
<td>14–N</td>
<td>Payload data</td>
</tr>
</tbody>
</table>

VLAN-tagged frames are supported on both transmit and receive, and implement additional information (VLAN type and info).

**Table 41-41. FIFO interface VLAN frame format**

<table>
<thead>
<tr>
<th>Byte number</th>
<th>Field</th>
</tr>
</thead>
<tbody>
<tr>
<td>0–5</td>

<td>VLAN tag and info</td>
</tr>
<tr>
<td>16–17</td>
<td>Length/type field</td>
</tr>
<tr>
<td>18–N</td>
<td>Payload data</td>
</tr>
</tbody>
</table>

**Note**

The standard defines that the LSB of the MAC address is sent/received first, while for all the other header fields — in other words, length/type, VLAN tag, VLAN info, and pause quanta — the MSB is sent/received first.

**41.7.15.2 Data structure examples**
If CRC forwarding is enabled \((\text{CRCFWD} = 0)\), the last four valid octets of the frame contain the FCS field. The non-significant bytes of the last word can have any value.

### 41.7.15.3 Frame status

A MAC layer status word and an accelerator status word is available in the receive buffer descriptor.

See Enhanced buffer descriptors for details.

The status is available with each frame with the last data of the frame.

If the frame status contains a MAC layer error (for example, CRC or length error), \(\text{RxBD}[\text{ME}]\) is also set with the last data of the frame.
41.7.16 FIFO protection

The following sections describe the FIFO protection mechanisms.

41.7.16.1 Transmit FIFO underflow

During a frame transfer, when the transmit FIFO reaches the almost empty threshold with no end-of-frame indication stored in the FIFO, the MAC logic:

- Stops reading data from the FIFO
- Asserts the MII error signal (MII_TXER) (1 in Figure 41-16) to indicate that the fragment already transferred is not valid
- Deasserts the MII transmit enable signal (MII_TXEN) to terminate the frame transfer (2)

After an underflow, when the application completes the frame transfer (3), the MAC transmit logic discards any new data available in the FIFO until the end of packet is reached (4) and sets the enhanced TxBD[UE] field.

The MAC starts to transfer data on the MII interface when the application sends a new frame with a start of frame indication (5).

![Figure 41-16. Transmit FIFO underflow protection](image-url)
## 41.7.16.2 Transmit FIFO overflow

On the transmit path, when the FIFO reaches the programmable almost full threshold, the internal MAC ready signal is deasserted. The application should stop sending new data.

However, if the application keeps sending data, the transmit FIFO overflows, corrupting contents that were previously stored. The core logic sets the enhanced TxBD[OE] field for the next frame transmitted to indicate this overflow occurrence.

**Note**

Overflow is a fatal error and must be addressed by resetting the core or clearing ENETn_ECR[ETHER_EN], to clear the FIFOs and prepare for normal operation again.

## 41.7.16.3 Receive FIFO overflow

During a frame reception, if the client application is not able to receive data (1), the MAC receive control truncates the incoming frame when the FIFO reaches the programmable almost-full threshold to avoid an overflow.

The frame is subsequently received on the FIFO interface with an error indication (enhanced RxBD[ME] field set together with receive end-of-packet) (2) with the truncation error status field set (3).

![Figure 41-17. Receive FIFO overflow protection](image)

i.MX RT1060 Processor Reference Manual, Rev. 2, 12/2019

NXP Semiconductors
41.7.17 PHY management interface

The MDIO interface is a two-wire management interface. The MDIO management interface implements a standardized method to access the PHY device management registers.

The core implements a master MDIO interface, which can be connected to up to 32 PHY devices.

41.7.17.1 MDIO clause 22 frame format

The core MDIO master controller communicates with the slave (PHY device) using frames that are defined in the following table.

A complete frame has a length of 64 bits made up of an optional 32-bit preamble, 14-bit command, 2-bit bus direction change, and 16-bit data. Each bit is transferred on the rising edge of the MDIO clock (MDC signal). The MDIO data signal is tri-stated between frames.

The core PHY management interface supports the standard MDIO specification (IEEE 802.3 Clause 22).

<table>

| PHYADR | Five-bit PHY device address, programmed with ENETn_MMFR[PA]. Up to 32 devices can be addressed. |
| REGADR | Five-bit register address, programmed with ENETn_MMFR[RA]. Each PHY can implement up to 32 registers. |
| TA     | Turnaround time, programmed with ENETn_MMFR[T]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase. |
| Data   | Data, set by ENETn_MMFR[DATA]. Written to or read from the PHY |
41.7.17.2 MDIO clause 45 frame format

The extended MDIO frame structure defined in IEEE 802.3 Clause 45 introduces indirect addressing. First, a write transaction to an address register is done, followed by a write or read transaction which will put the 16-bit data in the register or retrieve the register contents respectively. A preamble of 32 bits of logical ones is sent prior to every transaction. The MDIO data signal is tri-stated between frames.

The extended MDIO defines four transactions, which are determined by the two-bit opcode field.

Table 41-44. MDIO clause 45 frame structure

<table>
<thead>
<tr>
<th>ST</th>
<th>OP</th>
<th>PRTAD</th>
<th>DEVAD</th>
<th>TA</th>
<th>ADDR/DATA</th>
</tr>
</thead>
</table>

All bits are transmitted from left to right (Preamble bits first) and all fields have their Most-Significant bit sent first (leftmost in above table). The complete frame has a length of 64 bits (32-bit preamble, 14-bit command, 2-bit bus direction change, 16-bit data). Each bit is transferred with the rising edge of the MDIO clock (MDC).

The fields and transactions are summarized in the following tables.

Table 41-45. MDIO clause 45 frame field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ST</td>
<td>Start indication. Indicates the end of the preamble and start of the frame. This value is 00 for extended MDIO (Clause 45) frames.</td>
</tr>
<tr>
<td>OP</td>
<td>Opcode defines if a read or write operation is performed and is programmed with ENETn.MMFR[OP]. See Table 41-46 for more information. &lt;br&gt; 00 Address write &lt;br&gt; 01 Write operation &lt;br&gt; 10 Read inc. operation &lt;br&gt; 11 Read operation</td>
</tr>
<tr>
<td>PRTAD</td>
<td>The port address specifies a MDIO port. Each Port can have up to 32 devices which each can have a separate set of registers.</td>
</tr>
<tr>
<td>DEVAD</td>
<td>Device address. Up to 32 devices can be addressed (within a port).</td>
</tr>
<tr>
<td>TA</td>
<td>Turnaround time, programmed with ENETn.MMFR[TA]. Two bit-times are reserved for read operations to switch the data bus from write to read. The PHY device presents its register contents in the data phase and drives the bus from the second bit of the turnaround phase.</td>
</tr>
</tbody>
</table>

</thead>
<tbody>
<tr>
<td>Address</td>
<td>A write transaction to the internal address register of the device/port. The data section of the frame contains the value to be stored in the device’s internal address &quot;pointer&quot; register for further transactions.</td>
</tr>
<tr>
<td>Write</td>
<td>Data write to a register. The 16 bit data will be written to the register identified by the device-internal address.</td>
</tr>
<tr>
<td>Read</td>
<td>Data is read from the register identified by the device-internal address.</td>
</tr>
<tr>
<td>Read inc.</td>
<td>Read with address postincrement. The register identified by the device-internal address is read. After this, the device-internal address is incremented. If the address register is all '1' (0xFFFF) no increment is done (i.e. increment does not wrap around).</td>
</tr>
</tbody>
</table>

41.7.17.3 MDIO clock generation

The MDC clock is generated from the internal bus clock (i.e., IPS bus clock) divided by the value programmed in ENET\_MSCR[MII\_SPEED].
41.7.17.4 MDIO operation

To perform an MDIO access, set the MDIO command register (ENETn_MMFR) according to the description provided in MII Management Frame Register (ENETn_MMFR).

To check when the programmed access completes, read the ENETn_EIR[MII] field.

![Diagram](image)

**Figure 41-18. MDIO access overview**

41.7.18 Ethernet interfaces

The following Ethernet interfaces are implemented:

- Fast Ethernet MII (Media Independent Interface)
- RMII 10/100 using interface converters/gaskets

The following table shows how to configure ENET registers to select each interface.

<table>
<thead>
<tr>
<th>Mode</th>

</tr>
<tr>
<td>RMII - 100 Mbit/s</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

41.7.18.1 RMII interface

In RMII receive mode, for normal reception following assertion of CRS_DV, RXD[1:0] is 00 until the receiver determines that the receive event has a proper start-of-stream delimiter (SSD).
The preamble appears (RXD[1:0]=01) and the MACs begin capturing data following detection of SFD.

If a false carrier is detected (bad SSD), then RXD[1:0] is 10 until the end of the receive event. This is a unique pattern since a false carrier can only occur at the beginning of a packet where the preamble is decoded (RXD[1:0] = 01).

In RMII transmit mode, TXD[1:0] provides valid data for each REF_CLK period while TXEN is asserted.
41.7.18.2 MII Interface — transmit

On transmit, all data transfers are synchronous to MII_TXCLK rising edge. The MII data enable signal MII_TXEN is asserted to indicate the start of a new frame, and remains asserted until the last byte of the frame is present on the MII_TXD[3:0] bus.

Between frames, MII_TXEN remains deasserted.

If a frame is received on the FIFO interface with an error (for example, RxBD[ME] set) the frame is subsequently transmitted with the MII_TXER error signal for one clock cycle at any time during the packet transfer.
41.7.18.2.1 Transmit with collision — half-duplex

When a collision is detected during a frame transmission (MII_COL asserted), the MAC stops the current transmission, sends a 32-bit jam pattern, and re-transmits the current frame.

(See Collision detection in half-duplex mode for details)

![Figure 41-24. MII transmit operation — transmission with collision](image)

41.7.18.3 MII interface — receive

On receive, all signals are sampled on the MII_RXCLK rising edge. The MII data enable signal, MII_RXDV, is asserted by the PHY to indicate the start of a new frame and remains asserted until the last byte of the frame is present on MII_RXD[3:0] bus.

Between frames, MII_RXDV remains deasserted.

![Figure 41-25. MII receive operation](image)
If the PHY detects an error on the frame received from the line, the PHY asserts the MII error signal, MII_RXER, for at least one clock cycle at any time during the packet transfer.

![Figure 41-26. MII receive operation — errored frame](image)

A frame received on the MII interface with a PHY error indication is subsequently transferred on the FIFO interface with RxBD[ME] set.

### 41.7.19 Interrupt coalescence

The purpose of the interrupt coalescing is to reduce the number of interrupts generated by the MAC so as to reduce the CPU loading.

To facilitate this interrupt coalescing, these registers are available with the same control and configuration fields.

- Transmit Interrupt Coalescing Register (ENET_TXIC)
- Receive Interrupt Coalescing Register (ENET_RXIC)

When coalescing is enabled by asserting the corresponding ICEN field and such interrupt is also enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt when the threshold number of frames is reached (defined by ICFT) or when the threshold timer expires (defined by ICTT).

When coalescing is disabled by de-asserting ICEN, but interrupt is enabled by the corresponding interrupt mask of the EIMR register, the MAC generates an interrupt as they are received without using coalescing. Interrupt coalescing is done for each transmit and receive queue/class independently.
41.7.19.1 Interrupt coalescence setup
Interrupt coalescence supports both legacy and enhanced BDs. The following guidelines are recommended when setting up interrupt coalescence.

• When the MAC is configured for enhanced (IEEE 1588) mode, that is, enhanced BDs:
  • Set the INT bit in the enhanced received buffer descriptor to one.
  • Set the INT bit in the enhanced transmit buffer descriptor(s) to one.
  • Clear the TXB and RXB fields in the EIMR register.

41.7.19.2 Updating the frame count threshold on-the-fly
To update the ICFT field in the RXIC and TXIC registers:
1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

   **NOTE**
   When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new threshold value to the ICFT field.
3. Set ICEN to one.

   **NOTE**
   The ICFT field can be updated on-the-fly without disabling the ICEN field. The hardware interrupt will continue and there is a possibility that an interrupt will occur depending on the state of the hardware counter and the previous ICFT value.

41.7.19.3 Updating the timer threshold on-the-fly
To update the ICTT field in the RXIC and TXIC registers:
1. Disable interrupt coalescence by clearing the appropriate ICEN field. This will allow the internal interrupt coalescence counter to reset to zero.

   **NOTE**
   When disabling interrupt coalescence, if an interrupt event is pending, that is, the interrupt counter is not zero, then an interrupt will occur.

2. Write the new timer value to the ICTT field.
3. Set ICEN to one.

42.2 Overview

The USB controller block provides high performance USB functionality that conforms to the *Universal Serial Bus Specification*, Rev. 2.0 (Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips; 2000), and the *On-The-Go and Embedded Host Supplement to the USB Revision 2.0 Specification* (Hewlett-Packard Company, Intel Corporation, LSI Corporation, Microsoft Corporation, Renesas Electronics Corporation, ST-Ericsson; 2012).

The USB controller consists of two independent USB controller cores: two On-The-Go (OTG) controller cores. Each controller core supports UTMI interfaces according to its feature. See Features for more details. Both the controller cores are single-port cores. For the OTG cores, there is only one port. The port can be used as either a downstream or an upstream port.
The following figure is a block diagram of USB.

Figure 42-1. USB block diagram
42.2.1 Features

There are two USB 2.0 controller cores in this chip:
- Controller Core 0 is also named 'OTG1 Core'; its connected port is named 'OTG1 port'.
- Controller Core 1 is also named 'OTG2 Core'; its connected port is named 'OTG2 port'.

The following list provides features of each controller core.

- **USB 2.0 Controller Core 0**
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface
  - High Speed, Full Speed and Low Speed operation in HOST mode (with UTMI transceiver)
  - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
  - Up to 8 bidirectional endpoints
  - Support charger detection

- **USB 2.0 Controller Core 1**
  - High-Speed/Full-Speed/Low-Speed OTG core
  - HS/FS/LS UTMI compliant interface
  - High Speed, Full Speed and Low Speed operation in Host mode (with UTMI transceiver)
  - Hardware support for OTG signaling, session request protocol, and host negotiation protocol
  - Up to 8 bidirectional endpoints
  - Low-power mode with local and remote wake-up capability
  - Serial PHY interfaces configurable for bidirectional/unidirectional and differential/single ended
  - Embedded DMA controller in each core

42.2.2 Modes of Operation

The USB has two main modes of operation: normal mode and low power mode.
Each USB OTG controller core can operate in High Speed operation (480 Mbps), Full Speed operation (12 Mbps) and Low Speed operation (1.5 Mbps).

This chapter explains the operation modes.

42.2.2.1 Normal Mode

The OTG controller core can operate in Host mode and Device (Peripheral) mode.

Each USB controller core has its corresponding port, which can work in one or more interface modes.

**NOTE**

Each controller supports only the interface type listed below. Selecting a different interface type in the PORTSC_PTS field results in unpredictable behavior and may cause the system to hang.

- OTG1 port
  - This port supports on-chip UTMI transceiver only.
- OTG2 port
  - This port supports on-chip UTMI transceiver only.

42.2.2.2 Low-Power Mode

Each USB controller core has a low-power mode (Suspend mode) to save power consumption.

As described in the USB 2.0 specification, the device can go into the Suspend state after it sees a constant Idle state on the upstream facing port. The OTG controller core enters Suspend mode after 3 ms of inactivity on the port when it is in Device Operation mode. Host controllers, including the OTG controller in Host mode, do not suspend automatically but can be placed in Suspend mode by software.

Either the local Arm platform or the remote USB Host/Peripheral can initiate a wake-up sequence to resume USB communication. For details about Suspend/Resume, see USB Power Control.
42.3 External Signals

The table found here describes the external signals of USB.

42.4 Functional Description

These sections describe the functionality of the various building blocks of the USB.

42.4.1 USB 2.0 Controller Core 0

The USB 2.0 Controller 0 is an instantiation of an EHCI-compatible core which supports high-, full-, and low-speed operation.

In Host mode, this controller core supports high-, full-, and low-speed operation. In Device mode, it supports high- and full-speed operation.

42.4.1.1 Host Mode

The controller supports direct connection of a HS/FS/LS device with on-chip UTMI transceiver.
Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a USB 2.0 high speed hub has been implemented within the DMA and protocol engine blocks to support connection to full and low speed devices.

42.4.1.2 Peripheral (Device) Mode

- Up to eight bidirectional endpoints
- High/full-speed operation
- Support of HNP, and SRP
- Remote wake-up capability

42.4.2 USB 2.0 Controller Core 1

USB 2.0 Controller Core 1 is an instantiation of EHCI-compatible core which supports High Speed / Full Speed / Low Speed operation.

42.4.3 USB Power Control

The USB controller supports suspend and wake-up functionality.

The power control block allows for placing the transceiver in USB low power mode when USB bus is IDLE, and supports local and remote wake-up to bring the transceiver out of USB low power mode when needed. Additionally, the power control block can wake-up the Arm platform from core sleep mode by generating an interrupt.

42.4.3.1 Entering Low Power Suspend Mode

In Host operation mode, low power suspend mode is entered as follows:

1. Clear the ASE and PSE bits in USB_USBCMD, and wait until the AS and PS bits in USB_USBSTS become "0".
2. Set the "SUSPEND" bit in USB_PORTSC1
3. Set the "PHCD" bit in USB_PORTSC1
4. Set all PWD bits in USBPHYx_PWD
5. Set CLKGATE in USBPHYx_CTRL

NOTE
Step 3,4,5 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.
For device operation mode, low power suspend mode is entered as follows:

1. After Host drive is IDLE for 3ms, an SLI interrupt is issued (the "DCSUSPEND" or "SLI" bit in USB_USBSTS)
2. Set the "PHCD" bit on USB_PORTSC1
3. Set all PWD bits in USBPHYx_PWD
4. Set CLKGATE in USBPHYx_CTRL

**NOTE**

Step 2,3,4 shall be done in atomic operation. That is, interrupt should be disabled during these three steps.

### 42.4.3.2 Wake-Up Events

The power control block monitors the USB bus when the USB core is in the USB suspend state.

Depending on whether the core is on Host or Device mode, a number of wake-up conditions are monitored. Upon detection of a wake-up condition, an interrupt will be generated to Arm platform if the related wake-up interrupt enable bit is set.

USB wake-up interrupt also re-activates the Arm platform clocks if they were stopped during the suspend.

#### 42.4.3.2.1 Host Mode Events

The host controller wakes up on the following events:

- Remote Wake-up Request

A peripheral can request the host to reactivate the bus by driving wake-up signaling on the DM/DP lines. The power control block sends a wake-up request to the USB core when a J-K transition on DM/DP line is detected.

- Wake-Up On Overcurrent

If Wake-Up On Overcurrent is enabled (WKOC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when an overcurrent event is detected.

- Wake-Up On Disconnect
If Wake-Up On Disconnect is enabled (WKDC bit in the USB core register PORTSC1 is set '1'), the power control block sends a wake-up request to the USB core when a disconnection event is detected (J-SE0/K-SE0 transition on DM/DP line).

- Wake-Up On Connect

If a Wake-Up On Connect is enabled (WKCN bit in the USB core register PORTSC1 is set '1'), the power control sub-block sends a wake-up request to the USB core when the connection event is detected (SE0-J/SE0-K transition on DM/DP line).

For a detailed description of register bits WKOC, WKDC, WKCN, please see Port Status & Control (USB_PORTSC1).

42.4.4 Interrupts

42.4.4.1 USB Core Interrupts

Each USB core uses one dedicated vector in the Interrupt Table. The vector numbers associated with each of the cores can be found in the Interrupt section.

With the exception of the wake-up interrupts, all of the interrupt sources are controlled in the USB Cores. Refer to the Interrupt Enable Register (USB_USBINTR) for details.

42.4.4.2 USB Wake-Up Interrupts

Each USB Core has an associated wake-up interrupt. The wake-up interrupts are generated outside of the USB controller cores, but using the same vector as the corresponding USB controller cores interrupt.

These interrupts are generated by the Power Control blocks which run on the 32 KHz standby clock. The wake-up interrupt is designed to work even when the USB and Arm platform clocks are disabled, such that a wake-up condition on the USB bus can reactivate the Arm platform clocks.

Because the wake-up interrupt is generated and cleared on a 32 KHz clock, this interrupt request responds very slowly to clear actions. For this reason, the software must disable the wake-up interrupt to clear the request flag. Disabling the interrupt masks the request instantaneously as this is clocked by the Arm platform clock. The software should wait for at least three 32 KHz clock cycles before re-enabling this interrupt to allow sufficient
time for the request flag to clear. Because this interrupt is only used during low power modes of the USB, it is sufficient to enable the wake-up interrupt just prior to entering the USB suspend mode.

42.5 USB Operation Model

This section describes the detailed application knowledge for OTG1 and OTG2 ports.

42.5.1 Register Interface

Configuration, control and status registers are divided into three categories, identification, capability and operational registers.

**NOTE**

USB controller registers support only DWORD (32-bit) access.

- Identification registers are used to declare the slave interface presence along with the complete set of the hardware configuration parameters.
- Static, read only capability registers define the software limits, restrictions, and capabilities of the host/device controller.
- Operational registers are dynamic control or status registers that may be read only, read/write, or read/write-to-clear. The following sections define the use of these registers.

EHCI registers are listed alongside device registers to show the complementary nature of host and device control.

The following table describes the Interface register sets.

<table>
<thead>
<tr>
<th>Offset</th>
<th>Register Set</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>000h-07Ch</td>
<td>Identification Registers</td>
<td>Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.</td>

"X" means the register is reserved in host/device operation mode.
42.5.1.2 Identification Registers

Identification registers are used to declare the slave interface presence and include a table of the hardware configuration parameters.

42.5.1.3 OTG Operations

42.5.2 Host Data Structures

This section defines the interface data structures used to communicate control, status, and data between HCD (software) and the Enhanced Host Controller (hardware).

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of a Periodic Schedule, Periodic Frame List, Asynchronous Schedule, Isochronous Transaction Descriptors, Split-transaction Isochronous Transfer Descriptors, Queue Heads, and Queue Element Transfer Descriptors.

The periodic frame list is the root of all periodic (isochronous and interrupt transfer type) transfers for the host controller. The asynchronous list is the root for all the bulk and control transfers. Isochronous data streams are managed using Isochronous Transaction Descriptors. Isochronous split-transaction data streams are managed with Split-transaction Isochronous Transfer Descriptors. All Interrupt, Control, and Bulk data streams are managed via queue heads and Queue Element Transfer Descriptors. These data structures are optimized to reduce the total memory footprint of the schedule and to reduce (on average) the number of memory accesses needed to execute a USB transaction.

Note that software must ensure that no interface data structure reachable by the EHCI host controller spans a 4 K-page boundary.

The data structures defined in this section are (from the host controller's perspective) a mix of read-only and read/writeable fields. The host controller must preserve the read-only fields on all data structure writes.

42.5.2.1 Periodic Frame List

This schedule is for all periodic transfers (isochronous and interrupt). The periodic schedule is referenced from the operational registers space using the USB_PERIODICLISTBASE address register and the USB_FRINDEX register.

The periodic schedule is based on an array of pointers called the Periodic Frame List.
The USB_PERIODICLISTBASE address register is combined with the USB_FRINDEX register to produce a memory pointer into the frame list. The Periodic Frame List implements a sliding window of work over time.

The following figure shows the organization of periodic schedule.

![Figure 42-2. Periodic Schedule Organization](image)

Split transaction Interrupt, Bulk and Control are also managed using queue heads and queue element transfer descriptors.

The periodic frame list is a 4 K-page aligned array of Frame List Link pointers. The length of the frame list may be programmable. The programmability of the periodic frame list is exported to system software via the USB_HCCPARAMS register. If non-programmable, the length is 1024 elements. If programmable, the length can be selected by system software as one of 256, 512, or 1024 elements. An implementation must support all three sizes. Programming the size (that is, the number of elements) is accomplished by system software writing the appropriate value into Frame List Size field in the USB_USBCMD register.

Frame List Link pointers direct the host controller to the first work item in the frame's periodic schedule for the current micro-frame. The link pointers are aligned on DWord boundaries within the Frame List.
The table below illustrates the format of the Frame list element pointer.

### Table 42-5. Format of Frame List Element Pointer

| 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|----|
| Frame List Link Pointer | 0  | Typ | 03-00H |

Frame List Link pointers always reference memory objects that are 32-byte aligned. The referenced object may be an isochronous transfer descriptor for high-speed devices, a split-transaction isochronous transfer descriptor (for full-speed isochronous endpoints), or a queue head (used to support high-, full- and low-speed interrupt). System software should not place non-periodic schedule items into the periodic schedule. The least significant bits in a frame list pointer are used to key the host controller as to the type of object the pointer is referencing.

The least significant bit is the T-Bit (bit 0). When this bit is set to a one, the host controller never uses the value of the frame list pointer as a physical memory pointer. The Typ field is used to indicate the exact type of data structure being referenced by this pointer. The value encodings are.

</tbody>
</table>

#### 42.5.2.2 Asynchronous List Queue Head Pointer

The Asynchronous Transfer List (based at the USB_ASYNCLISTADDR register) is where all of the control and bulk transfers are managed.

Host controllers use this list only when it reaches the end of the periodic list, the periodic list is disabled, or the periodic list is empty.
AsynListAddr

Operational
Registers

Bulk/Control Queue Heads

Asynchronous Schedule Organization

Figure 42-3. Asynchronous Schedule Organization

The Asynchronous list is a simple circular list of queue heads. The USB_ASYNCLISTADDR register is simply a pointer to the next queue head. This implements a pure round-robin service for all queue heads linked into the asynchronous list.

42.5.2.3 Isochronous (High-Speed) Transfer Descriptor (iTD)

The format of an isochronous transfer descriptor is shown in the table below. This structure is used only for high-speed isochronous endpoints. All other transfer types should use queue structures. Isochronous TDs must be aligned on a 32-byte boundary.

<table>
<thead>
<tr>
<th>Reserved</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>2-1 QH/(s)</td>
<td>This field indicates to the Host Controller whether the item referenced is an iTD, siTD or a QH. This allows the Host Controller to perform the proper type of processing on the item after it is fetched. Value encodings are: Value Meaning 00b iTD (isochronous transfer descriptor) 01b QH (queue head) 10b siTD (split transaction isochronous transfer descriptor) 11b FSTN (frame span traversal node)</td>
</tr>
<tr>
<td>0</td>
<td>1= Link Pointer field is not valid. 0= Link Pointer field is valid.</td>
</tr>
</tbody>
</table>

42.5.2.3.2 iTD Transaction Status and Control List

DWords 1 through 8 are eight slots of transaction control and status.

Each transaction description includes:

- Status results field
- Transaction length (bytes to send for OUT transactions and bytes received for IN transactions).
- Buffer offset. The PG and Transaction X Offset fields are used with the buffer pointer list to construct the starting buffer address for the transaction.

The host controller uses the information in each transaction description plus the endpoint information contained in the first three DWords of the Buffer Page Pointer list, to execute a transaction on the USB.

The following table describes iTD Transaction Status and Control fields.

Table 42-9. iTD Transaction Status and Control

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28 Status</td>
<td>This field records the status of the transaction executed by the host controller for this slot. This field is a bit vector with the following encoding:</td>
</tr>
<tr>
<td>Bit</td>
<td>Definition</td>
</tr>
<tr>
<td>31</td>
<td>Active. Set to one by software to enable the execution of an isochronous transaction by the Host Controller. When the transaction associated with this descriptor is completed, the Host Controller sets this bit to zero indicating that a transaction for this element should not be executed when it is next encountered in the schedule.</td>
</tr>
<tr>
<td>30</td>
<td>Data Buffer Error. Set to a one by the Host Controller during status update to indicate that the Host Controller is unable to keep up with the reception of incoming data (overrun) or is unable to supply data fast enough during transmission (under run). If an overrun condition occurs, no action is necessary.</td>
</tr>
<tr>
<td>29</td>
<td>Babble Detected. Set to one by the Host Controller during status update when &quot;babble&quot; is detected during the transaction generated by this descriptor.</td>
</tr>
</tbody>
</table>

Table continues on the next page...
Table 42-9. iTD Transaction Status and Control (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>28</td>
<td>Transaction Error (XactErr). Set to one by the Host Controller during status update in the case where the host did not receive a valid response from the device (Timeout, CRC, Bad PID, etc.). This bit may only be set for isochronous IN transactions.</td>
</tr>
<tr>
<td>27-16</td>
<td>Transaction X Length For an OUT, this field is the number of data bytes the host controller sends during the transaction. The host controller is not required to update this field to reflect the actual number of bytes transferred during the transfer. For an IN, the initial value of the endpoint to deliver. During the status update, the host controller writes back the field is the number of bytes the host expects the number of bytes successfully received. The value in this register is the actual byte count (0‡zero length data, 1‡one byte, 2‡two bytes, etc.). The maximum value this field may contain is 0xC00 (3072).</td>
</tr>
<tr>
<td>15</td>
<td>Interrupt On Complete (IOC) If this bit is set to one, it specifies that when this transaction completes, the Host Controller should issue an interrupt at the next interrupt threshold.</td>
</tr>
<tr>
<td>14-12</td>
<td>Page Select (PG) These bits are set by software to indicate which of the buffer page pointers the offset field in this slot should be concatenated to produce the starting memory address for this transaction. The valid range of values for this field is 0 to 6.</td>
</tr>
<tr>
<td>11-0</td>
<td>Transaction X Offset This field is a value that is an offset, expressed in bytes, from the beginning of a buffer. This field is concatenated onto the buffer page pointer indicated in the adjacent PG field to produce the starting buffer address for this transaction.</td>
</tr>
</tbody>
</table>

42.5.2.3.3 iTD Buffer Page Pointer List (Plus)

DWords 9-15 of an isochronous transaction descriptor are nominally page pointers (4 K aligned) to the data buffer for this transfer descriptor. This data structure requires the associated data buffer to be contiguous (relative to virtual memory), but allows the physical memory pages to be non-contiguous.

Seven page pointers are provided to support the expression of eight isochronous transfers. The seven pointers allow for 3 (transactions) * 1024 (maximum packet size) * 8 (transaction records) (24576 bytes) to be moved with this data structure, regardless of the alignment offset of the first page.

Because each pointer is a 4 K aligned page pointer, the least significant 12 bits in several of the page pointers are used for other purposes.

The tables below illustrate the field descriptions.

Table 42-10. iTD Buffer Pointer Page 0 (Plus)

<table>
<thead>
<tr>
<th>Bit</th>

42.5.2.4.4 siTD Buffer Pointer List (plus)

DWords 4 and 5 are the data buffer page pointers for the transfer. This structure supports one physical page cross. The most significant 20 bits of each DWord in this section are the 4 K (page) aligned buffer pointers.

The least significant 12 bits of each DWord are used as additional transfer state. The following table describes the siTD buffer pointer fields.

Table 42-19. Buffer Page Pointer List (plus)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-12</td>
<td>Buffer Pointer List. Bits [31:12] of DWords 4 and 5 are 4 K page aligned physical memory addresses. These bits correspond to physical address bits [31:12] respectively. The lower 12 bits in each pointer are defined and used as specified below. The field P (see siTD Transfer State) specifies the current active pointer.</td>
</tr>
<tr>
<td>Bits 11-0 (Page 0)</td>

</tr>
</tbody>
</table>

### 42.5.2.4.5 siTD Back Link Pointer

DWord 6 of a siTD is simply another schedule link pointer. This pointer is always zero, or references a siTD, and it cannot reference any other schedule data structure.

The following table describes the siTD back link pointer fields.

#### Table 42-20. siTD Back Link Pointer

<table>
<thead>
<tr>

</tr>
<tr>
<td>0</td>
<td>Terminate (T). 1 = siTD Back Pointer field is not valid. 0 = siTD Back Pointer field is valid.</td>
</tr>
</tbody>
</table>

### 42.5.2.5 Queue element transfer descriptor (qTD)

This data structure is only used with a queue head. It describes one or more USB transactions to transfer up to 20480 (5*4096) bytes.

The structure contains two structure pointers used for queue advancement, a DWord of transfer state, and a five-element array of data buffer pointers.

It is 32 bytes and must be physically contiguous.

The buffer associated with this transfer must be virtually contiguous. The buffer may start on any byte boundary; however, for optimal utilization of on-chip busses it is recommended to align the buffers on a 32-byte boundary. A separate buffer pointer list element must be used for each physical page in the buffer, regardless of whether the buffer is physically contiguous.

Host controller updates (host controller writes) to stand-alone qTDs only occur during transfer retirement. References in the following bit field definitions of updates to the qTD are to the qTD portion of a queue head.
The following table shows the queue element transfer descriptor data structure.

**Table 42-21. Queue element transfer descriptor data structure**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-5</td>
<td>Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.</td>
</tr>
<tr>
<td>4-1</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

Queue Element Transfer Descriptors must be aligned on 32-byte boundaries.

### 42.5.2.5.1 Next qTD Pointer

The first DWord of an element transfer descriptor is a pointer to another transfer element descriptor.

The following table describes Next qTD pointer fields.

**Table 42-22. qTD Next Element Transfer Pointer (DWord 0)**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed. The field corresponds to memory address signals[31:5], respectively.</td>
</tr>
<tr>
<td>4-1</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

Table continues on the next page...
### 42.5.2.5.2 Alternate Next qTD Pointer

The second DWord of a queue element transfer descriptor is used to support hardware-only advance of the data stream to the next transfer descriptor on short packet. To be more explicit, the host controller always uses this pointer when the current qTD is retired due to short packet.

The following table describes the TD Alternate Next Element Transfer Pointer field descriptions.

**Table 42-23. TD Alternate Next Element Transfer Pointer (DWord 1)**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-5</td>
<td>Alternate Next Transfer Element Pointer. This field contains the physical memory address of the next qTD to be processed in the event that the current qTD execution encounters a short packet (for an IN transaction). The field corresponds to memory address signals [31:5], respectively.</td>
</tr>
<tr>
<td>4-1</td>
<td>Reserved</td>
</tr>
<tr>
<td>0</td>
<td>Terminate (T). 1= pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Host Controller that there are no more valid entries in the queue.</td>
</tr>
</tbody>
</table>

### 42.5.2.5.3 qTD Token

The third DWord of a queue element transfer descriptor contains most of the information the host controller requires to execute a USB transaction (the remaining endpoint-addressing information is specified in the queue head).

**NOTE**

The field descriptions forward reference fields defined in the queue head. Where necessary, these forward references are preceded with a QH notation.

The following table describes the TD Token fields.

**Table 42-24. TD Token (DWord 2)**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

*Table continues on the next page...*
### Table 42-24. TD Token (DWord 2) (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>30-16</td>
<td><strong>Total Bytes to Transfer</strong>&lt;br&gt;This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction, only on the successful completion of the transaction. The maximum value software may store in this field is $5 \times 4\text{K} (5000\text{H})$. This is the maximum number of bytes 5 page pointers can access. If the value of this field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the host controller executes a zero-length transaction and retires the transfer descriptor. It is not a requirement for OUT transfers that <em>Total Bytes To Transfer</em> be an even multiple of QHD.Maximum Packet Length. If software builds such a transfer descriptor for an OUT transfer, the last transaction is always less than QHD.Maximum Packet Length.&lt;br&gt;Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16 K(4000H).</td>
</tr>
<tr>
<td>15</td>
<td><strong>Interrupt On Complete (IOC)</strong>&lt;br&gt;If this bit is set to a one, it specifies that when this qTD is completed, the Host Controller should issue an interrupt at the next interrupt threshold.</td>
</tr>
<tr>
<td>14-12</td>
<td><strong>Current Page (C_Page)</strong>&lt;br&gt;This field is used as an index into the qTD buffer pointer list. Valid values are in the range 0H to 4H. The host controller is not required to write this field back when the qTD is retired.</td>
</tr>
<tr>
<td>11-10</td>
<td><strong>Error Counter (CERR)</strong>&lt;br&gt;This field is a 2-bit down counter that keeps track of the number of consecutive Errors detected while executing this qTD. If this field is programmed with a non-zero value during set-up, the Host Controller decrements the count and writes it back to the qTD if the transaction fails. If the counter counts from one to zero, the Host Controller marks the qTD inactive, sets the <em>Halted</em> bit to a one, and error status bit for the error that caused CERR to decrement to zero. An interrupt is generated if the <em>USB Error Interrupt Enable</em> bit in the USBINTR register is set to a one. If HCD programs this field to zero during set-up, the Host Controller does not count errors for this qTD and there is no limit on the retries of this qTD. Note that write-backs of intermediate execution state are to the queue head overlay area, not the qTD.&lt;br&gt;&lt;br&gt;<strong>Transaction Error - Decrement</strong>&lt;br&gt;<strong>Data Buffer Error - No Decrement</strong>³&lt;br&gt;<strong>Stalled - No Decrement</strong>¹&lt;br&gt;<strong>Babble Detected - No Decrement</strong>¹&lt;br&gt;<strong>No Error - No Decrement</strong>²&lt;br&gt;&lt;br&gt;<strong>Error Decrement Counter</strong>&lt;br&gt;&lt;br&gt;1&lt;sup&gt;1&lt;/sup&gt; Detection of Babble or Stall automatically halts the queue head. Thus, count is not decremented&lt;br&gt;&lt;br&gt;2&lt;sup&gt;2&lt;/sup&gt; If the EPS field indicates a HS device or the queue head is in the Asynchronous Schedule (and <em>PIDCode</em> indicates an IN or OUT) and a bus transaction completes and the host controller does not detect a transaction error, then the host controller should reset <em>CERR</em> to extend the total number of errors for this transaction. For example, <em>CERR</em> should be reset with maximum value (3) on each successful completion of a transaction. The host controller must never reset this field if the value at the start of the transaction is 00b.&lt;br&gt;&lt;br&gt;See Split Transaction Interrupt for CERR adjustment rules when the EPS field indicates a FS or LS device and the queue head is in the Periodic Schedule. See Asynchronous - Do Complete Split for CERR adjustment rules when the EPS field indicates a FS or LS device, the queue head is in the Asynchronous schedule and the <em>PIDCode</em> indicates a SETUP.</td>
</tr>
</tbody>
</table>

<tr>
<td></td>
<td>If the QH.EPS field does not indicate a High-speed device, then this field is used as an error indicator bit. It is set to a one by the host controller whenever a periodic split-transaction receives an ERR handshake.</td>
</tr>
</tbody>
</table>

42.5.2.5.4 qTD Buffer Page Pointer List

The last five DWords of a queue element transfer descriptor is an array of physical memory address pointers. These pointers reference the individual pages of a data buffer.

System software initializes Current Offset field to the starting offset into the current page, where current page is selected through the value in the C_Page field.

The following table describes the qTD Buffer Pointer(s) (DWords 3-7) fields.

Table 42-25. qTD Buffer Pointer(s) (DWords 3-7)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-12</td>
<td>Buffer Pointer List. Each element in the list is a 4 K page aligned physical memory address. The lower 12 bits in each pointer are reserved (except for the first one), as each memory pointer must reference the start of a 4 K page. The field C_Page specifies the current active pointer. When the transfer element descriptor is fetched, the starting buffer address is selected using C_Page (similar to an array index to select an array element). If a transaction spans a 4K buffer boundary, the host controller must detect the page-span boundary in the data stream, increment C_Page and advance to the next buffer pointer in the list, and conclude the transaction through the new buffer pointer.</td>
</tr>
<tr>
<td>11-0</td>
<td>Current Offset (Reserved). This field is reserved in all pointers except the first one (for example Page 0). The host controller should ignore all reserved bits. For the page 0 current offset interpretation, this field is the byte offset into the current page (as selected by C_Page). The host controller is not required to write this field back when the qTD is retired. Software should ensure the Reserved fields are initialized to zero.</td>
</tr>
</tbody>
</table>
42.5.2.6 Queue Head

The table located in this section shows the Queue Head structure layout.

The following table shows the queue head structure layout.

</tr>
<tr>
<td></td>
<td>11b FSTN (frame span traversal node)</td>
</tr>
<tr>
<td>0</td>
<td>Terminate (T). 1=Last QH (pointer is invalid). 0=Pointer is valid. If the queue head is in the context of the periodic list, a one bit in this field indicates to the host controller that this is the end of the periodic list. This bit is ignored by the host controller when the queue head is in the Asynchronous schedule. Software must ensure that queue heads reachable by the host controller always have valid horizontal link pointers.</td>
</tr>
</tbody>
</table>

42.5.2.6.2 Queue Head Endpoint Capabilities/Characteristics

The second and third DWords of a Queue Head specifies static information about the endpoint. This information does not change over the lifetime of the endpoint.

There are three types of information in this region:

- Endpoint Characteristics. These are the USB endpoint characteristics including addressing, maximum packet size, and endpoint speed.
- Endpoint Capabilities. These are adjustable parameters of the endpoint. They effect how the endpoint data stream is managed by the host controller.
- Split Transaction Characteristics. This data structure is used to manage full- and low-speed data streams for bulk, control, and interrupt via split transactions to USB2.0 Hub Transaction Translator. There are additional fields used for addressing the hub and scheduling the protocol transactions (for periodic).
The host controller must not modify the bits in this region.

The following table describes the Endpoint characteristics: Queue head DWord 1 fields.

### Table 42-28. Endpoint Characteristics: Queue Head DWord 1

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-28</td>
<td>Nak Count Reload (RL). This field contains a value, which is used by the host controller to reload the Nak Counter field.</td>
</tr>
<tr>
<td>27</td>
<td>Control Endpoint Flag (C). If the QH.EPS field indicates the endpoint is not a high-speed device, and the endpoint is a control endpoint, then software must set this bit to a one. Otherwise, it should always set this bit to zero.</td>
</tr>
<tr>
<td>26-16</td>
<td>Maximum Packet Length. This directly corresponds to the maximum packet size of the associated endpoint (wMaxPacketSize). The maximum value this field may contain is 0x400 (1024).</td>
</tr>
<tr>
<td>15</td>
<td>Head of Reclamation List Flag (H). This bit is set by System Software to mark a queue head as being the head of the reclamation list.</td>
</tr>
</tbody>
</table>
| 14   | Data Toggle Control (DTC). This bit specifies where the host controller should get the initial data toggle on an overlay transition.  
  0b Ignore DT bit from incoming qTD. Host controller preserves DT bit in the queue head.  
  1b Initial data toggle comes from incoming qTD DT bit. Host controller replaces DT bit in the queue head from the DT bit in the qTD. |
| 13-12| Endpoint Speed (EPS). This is the speed of the associated endpoint. Bit combinations are:  
  Value | Meaning |
  00b  | Full-Speed (12 Mbits/sec) |
  01b  | Low-Speed (1.5 Mbits/sec) |
  10b  | High-Speed (480 Mbits/sec) |
  11b  | Reserved |
  This field must not be modified by the host controller. |
| 11-8 | Endpoint Number (Endpt). This 4-bit field selects the particular endpoint number on the device serving as the data source or sink. |
| 7    | Inactivate on Next Transaction (I). This bit is used by system software to request that the host controller set the Active bit to zero. See Rebalancing the periodic schedule, for full operational details. This field is only valid when the queue head is in the Periodic Schedule and the EPS field indicates a Full or Low-speed endpoint. Setting this bit to one when the queue head is in the Asynchronous Schedule or the EPS field indicates a high-speed device yields undefined results. |
| 6-0  | Device Address. This field selects the specific device serving as the data source or sink. |

The table below describes the Endpoint capabilities: Queue head DWord 2 field descriptions.

<td>15-8</td>
<td>Split Completion Mask (μFrame C-Mask). This field is ignored by the host controller unless the EPS field indicates this device is a low- or full-speed device and this queue head is in the periodic list. This field (along with the Active and SplitX-state fields) is used to determine during which micro-frames the host controller should execute a complete-split transaction. When the criteria for using this field are met, a zero value in this field has undefined behavior. This field is used by the host controller to match against the three low-order bits of the FRINDEX register. If the FRINDEX register bits decode to a position where the μFrame C-Mask field is a one, then this queue head is a candidate for transaction execution. There may be more than one bit in this mask set.</td>
</tr>
<tr>
<td>7-0</td>
<td>Interrupt Schedule Mask (μFrame S-mask). This field is used for all endpoint speeds. Software should set this field to a zero when the queue head is on the asynchronous schedule. A non-zero value in this field indicates an interrupt endpoint. The host controller uses the value of the three low-order bits of the FRINDEX register as an index into a bit position in this bit vector. If the μFrame S-mask field has a one at the indexed bit position then this queue head is a candidate for transaction execution. If the EPS field indicates the endpoint is a high-speed endpoint, then the transaction executed is determined by the PID_Code field contained in the execution area. This field is also used to support split transaction types: Interrupt (IN/OUT). This condition is true when this field is non-zero and the EPS field indicates this is either a full- or low-speed device. A zero value in this field, in combination with existing in the periodic frame list has undefined results.</td>
</tr>
</tbody>
</table>

42.5.2.6.3 Transfer Overlay-Queue Head

The nine DWords in this area represent a transaction working space for the host controller. The general operational model is that the host controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it follows the Queue Head Horizontal Link Pointer to the next queue head. The host controller will never follow the Next Transfer Queue Element or Alternate Queue Element pointers unless it is actively attempting to advance the queue. For the duration of the transfer, the host controller keeps the incremental status of the transfer in the overlay area. When the transfer is complete, the results are written back to the original queue element.

The DWord3 of a Queue Head contains a pointer to the source qTD currently associated with the overlay. The host controller uses this pointer to write back the overlay area into the source qTD after the transfer is complete.

The following table describes the current qTD link pointer field descriptions.
**Table 42-30. Current qTD Link Pointer**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-5</td>
<td>Current Element Transaction Descriptor Link Pointer. This field contains the address of the current transaction being processed in this queue and corresponds to memory address signals [31:5], respectively.</td>
</tr>
<tr>
<td>4-0</td>
<td>Reserved (R). These bits are ignored by the host controller when using the value as an address to write data. The actual value may vary depending on the usage.</td>
</tr>
</tbody>
</table>

The DWords 4-11 of a queue head are the transaction overlay area. This area has the same base structure as a Queue Element Transfer Descriptor. The queue head utilizes the reserved fields of the page pointers to implement tracking the state of split transactions.

This area is characterized as an overlay because when the queue is advanced to the next queue element, the source queue element is merged onto this area. This area serves as execution cache for the transfer.

The table below describes the Host-controller rules for bits in overlay.

**Table 42-31. Host-Controller Rules for Bits in Overlay (DWords 5, 6, 8 and 9)**

<table>
<thead>
<tr>
<th>DWord</th>
<th>Bit</th>
<th>Description</th>

<td>4-0</td>
<td>Split-transaction Frame Tag (Frame Tag). This field is initialized to zero during any overlay. This field is used to track the progress of an interrupt split-transaction.</td>
</tr>
<tr>
<td>9</td>
<td>11-5</td>
<td>S-bytes. Software must ensure that the S-bytes field in a qTD is zero before activating the qTD. This field is used to keep track of the number of bytes sent or received during an IN or OUT split transaction.</td>
</tr>
</tbody>
</table>

### 42.5.2.7 Periodic Frame Span Traversal Node (FSTN)

This data structure is to be used only for managing Full- and Low-speed transactions that span a Host-frame boundary.
See Host Controller Operational Model for FSTNs for full operational details. Software must not use an FSTN in the Asynchronous Schedule. An FSTN in the Asynchronous schedule results in undefined behavior. Software must not use the FSTN feature with a host controller whose USB_HCIVERSION register indicates a revision implementation below 0096h. FSTNs are not defined for implementations before 0.96 and their use yields undefined results.

### Table 42-32. Frame Span Traversal Node Structure Layout

<td>Terminate (T). 1 = Link Pointer field is not valid. 0 = Link Pointer is valid.</td>
</tr>
</tbody>
</table>
**42.5.2.7.2 FSTN Back Path Link Pointer**

The second DWord of an FTSN node contains a link pointer to a queue head.

If the T-bit in this pointer is zero, then this FSTN is a Save-Place indicator. Its Typ field must be set by software to indicate the target data structure is a queue head. If the T-bit in this pointer is set to one, then this FSTN is the Restore indicator. When the T-bit is one, the host controller ignores the Typ field.

The following table describes the FSTN back path link pointer fields.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-5</td>
<td>Back Path Link Pointer (BPLP). This field contains the address of a Queue Head. This field corresponds to memory address signals [31:5], respectively.</td>
</tr>
<tr>
<td>4-3</td>
<td>Reserved</td>
</tr>
<tr>
<td>2-1</td>
<td>Typ. Software must ensure this field is set to indicate the target data structure is a Queue Head. Any other value in this field yields undefined results.</td>
</tr>
<tr>
<td>0</td>
<td>Terminate (T). 1=Link Pointer field is not valid (that is the host controller must not use bits [31:5] as a valid memory address). This value also indicates that this FSTN is a Restore indicator. 0=Link Pointer is valid (that is the host controller may use bits [31:5] (in combination with the CTRLDSSEGMENT register if applicable) as a valid memory address). This value also indicates that this FSTN is a Save-Place indicator.</td>
</tr>
</tbody>
</table>

**42.5.3 Host Operational Model**

The general operational model is for the enhanced interface host controller hardware and enhanced interface host controller driver (generally referred to as system software).

Each significant operational feature of the EHCI host controller is discussed in a separate section. Each section presents the operational model requirements for the host controller hardware. Where appropriate, recommended system software operational models for features are also presented.

**42.5.3.1 Host Controller Initialization**

After initial power-on or HReset (hardware or through HReset bit in the USB_USBCMD register), all of the operational registers are at their default values. After a hardware reset, only the operational registers not contained in the Auxiliary power well are at their default values.

The following table describes the default values of operational registers.
To initialize the host controller, software should perform the following steps:

- Write the appropriate value to the USB_USBINTR register to enable the appropriate interrupts.
- Write the base address of the Periodic Frame List to the USB_PERIODICLISTBASE register. If no work items are in the periodic schedule, all elements of the Periodic Frame List should have their T-Bits set to one.
- Write the USB_USBCMD register to set the desired interrupt threshold, frame list size (if applicable) and turn the host controller ON through setting the Run/Stop bit.

At this point, the host controller is up and running and the port registers begin reporting device connects, and so on. System software can enumerate a port through the reset process (where the port is in the enabled state). At this point, the port is active with SOFs occurring down the enabled ports, but the schedules have not enabled. To communicate with devices through the asynchronous schedule, system software must write the USB_ASYNCLISTADDR register with the address of a control or bulk queue head. Software must then enable the asynchronous schedule by writing one to the Asynchronous Schedule Enable bit in the USB_USBCMD register. To communicate with devices through the periodic schedule, system software must enable the periodic schedule by writing one to the Periodic Schedule Enable bit in the USB_USBCMD register.

**NOTE**

The schedules can be turned on before the first port is reset (and enabled).

When the USB_USBCMD register is written, system software must ensure the appropriate bits are preserved, depending on the intended operation.

---

</tbody>
</table>
42.5.3.2 Port Routing and Control

The EHCI specification defines that a USB 2.0 Host controller is comprised of one high-speed host controller, which implements the EHCI programming interface and 0 to N USB 1.1 companion host controllers.

Companion host controllers (cHCs) may be implementations of either Universal or Open host controller specifications. This configuration is used to deliver the required full USB 2.0-defined port capability; for example, Low-, Full-, and High-speed capability for every port.

**NOTE**

The USB controllers on do not require nor support companion controllers to support Full and Low Speed device. Full and Low Speed devices are supported within the USB controller by emulating the functionality of a high-speed HUB. Therefore, no port routing is present in the controller. Please refer to [Embedded Transaction Translator Function](#) for details.

The following figure illustrates a simple block diagram of the port routing logic and its relationship to the high-speed and companion host controllers within a USB 2.0 host controller.
There exists one transceiver per physical port and each host controller block has its own port status and control registers. The EHCI controller has port status and control registers for every port. Each companion host controller has only the port control and status registers it is required to operate. Either the EHCI host controller or one companion host controller controls each transceiver. Routing logic lies between the transceiver, the port status and control registers.

The port routing logic is controlled from signals originating in the EHCI host controller. The EHCI host controller has a global routing policy control field and per-port ownership control fields. The Configured Flag (CF) bit is the global routing policy control. At power-on or reset, the default routing policy is to the companion controllers (if they exist). If the system does not include a driver for the EHCI host controller and the host controller includes Companion Controllers, then the ports still work in Full- and Low-speed mode (assuming the system includes a driver for the companion controllers). In general, when the EHCI owns the ports, the companion host controllers’ port registers do not see a connect indication from the transceiver. Similarly, when a companion host controller owns a port, the EHCI controller's port registers do not see a connect indication.

---

1. The routing logic should not be implemented in the 480 MHz clock domain of the transceiver.
from the transceiver. The details on the rules for the port routing logic are described in the following sections. The USB 2.0 host controller must be implemented as a multi-function PCI device if the implementation includes companion controllers. The companion host controllers' function numbers must be less than the EHCI host controller function number. The EHCI host controller must be a larger function number with respect to the companion host controllers associated with this EHCI host controller. If a PCI device implementation contains only an EHCI controller (that is no companion controllers or other PCI functions), then the EHCI host controller must be function zero, in accordance with the PCI Specification. The N_CC field in the Structural Parameter register (HCSPARMS) indicates whether the controller implementation includes companion host controllers. When N_CC has a non-zero value there exists companion host controllers. If N_CC has a value of zero, then the host controller implementation does not include companion host controllers. If the host controller root ports are exposed to attachment of full- or low-speed devices, the ports always fails the high-speed chirp during reset and the ports are not enabled. System software can notify the user of the illegal condition. This type of implementation requires a USB 2.0 hub be connected to a root port to provide full and low-speed device connectivity.

System software uses information in the host controller capability registers to determine how the ports are routed to the companion host controllers. See Host Controller Structural Parameters (USB_nHCSPARMS)

42.5.3.2.1 Port Routing Control through EHCI Configured (CF) Bit

Each port in the USB 2.0 host controller are routed either to a single companion host controller or to the EHCI host controller.

The port routing logic is controlled by two mechanisms in the EHCI HC: a host controller global flag and per-port control. The Configured Flag (CF) bit, is used to globally set the policy of the routing logic. Each port register has a Port Owner control bit which allows the EHCI Driver to explicitly control the routing of individual ports. Whenever the CF bit transitions from zero to one (this transition is only available under program control) the port routing unconditionally routes all of the port registers to the EHCI HC (all Port Owner bits go to zero). While the CF-bit is one, the EHCI Driver controls individual ports' routing through the Port Owner control bit. Likewise, whenever the CF bit transitions from one to zero (as a result of Aux power application, HCRESET, or software writing zero to CF-bit), the port routing unconditionally routes all of the port registers to the appropriate companion HC. The default value for the EHCI HC's CF bit (after Aux power application or HCRESET) is zero.
The view of the port depends on the current owner. A Universal or Open companion host controller will see port register bits consistent with the appropriate specification. Port bit definitions that are required for EHCI host controllers are not visible to companion host controllers.

The following table summarizes the default routing for all the ports, based on the value of the EHCI HC’s CF bit.

<table>
<thead>
<tr>
<th>HS CF Bit</th>
<th>Default Port Ownership</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0B</td>
<td>Companion HCs</td>
<td>The companion host controllers own the ports and only Full- and Low-speed devices are supported in the system. The exact port assignments are implementation dependent. The ports behave only as Full- and Low-speed ports in this configuration.</td>
</tr>
<tr>
<td>1B</td>
<td>EHCI HC</td>
<td>The EHCI host controller has default ownership over all of the ports. The routing logic inhibits device connect events from reaching the companion HCs’ port status and control registers when the port owner is the EHCI HC. The EHCI HC has access to the additional port status and control bits defined in this specification (see Port Status &amp; Control (USB_PORTSC1)). The EHCI HC can temporarily release control of the port to a companion HC by setting the PortOwner bit in the PORTSC1 register to one.</td>
</tr>
</tbody>
</table>

**42.5.3.2.2 Port Routing Control through PortOwner and Disconnect Event**

Manipulating the port routing through the CF-bit is an extreme process and not intended to be used during normal operation.

The normal mode of port ownership transferal is on the granularity of individual ports using the Port Owner bit in the EHCI HC's USB_PORTSC1 register (for hand-offs from EHCI to companion host controllers). Individual port ownership is returned to the EHCI controller when the port registers a device disconnect. When the disconnect is detected, the port routing logic immediately returns the port ownership to the EHCI controller. The companion host controller port register detects the device disconnect and operates normally.

Under normal operating conditions (assuming all HC drivers loaded and operational and the EHCI CF-bit is set to one), the typical port enumeration sequence proceeds as illustrated below:

- Initial condition is that EHCI is port owner. A device is connected causing the port to detect a connect, set the port connect change bit and issue a port-change interrupt (if enabled).
- EHCI Driver identifies the port with the new connect change bit asserted and sends a change report to the hub driver. Hub driver issues a GetPortStatus() request and
identifies the connect change. It then issues a request to clear the connect change, followed by a request to reset and enable the port.

- When the EHCI Driver receives the request to reset and enable the port, it first checks the value reported by the LineStatus bits in the USB_PORTSC1 register. If they indicate the attached device is a full-speed device (for example, D+ is asserted), then the EHCI Driver sets the PortReset control bit to one (and sets the PortEnable bit to zero) which begins the reset-process. Software times the duration of the reset, then terminates reset signaling by writing zero to the port reset bit. The reset process is actually complete when software reads zero in the PortReset bit. The EHCI Driver checks the PortOwner bit in the USB_PORTSC1 register. If set to one, the connected device is a high-speed device and EHCI Driver (root hub emulator) issues a change report to the hub driver and the hub driver continues to enumerate the attached device.

- At the time the EHCI Driver receives the port reset and enable request the LineStatus bits might indicate a low-speed device. Additionally, when the port reset process is complete, the PortEnable field may indicate that a full-speed device is attached. In either case the EHCI driver sets the PortOwner bit in the USB_PORTSC1 register to one to release port ownership to a companion host controller.

- When the EHCI Driver sets PortOwner bit to one, the port routing logic makes the connection state of the transceiver available to the companion host controller port register and removes the connection state from the EHCI HC port. The EHCI USB_PORTSC1 register observes and reports a disconnect event through the disconnect change bit. The EHCI Driver detects the connection status change (either by polling or by port change interrupt) and then sends a change report to the hub driver. When the hub driver requests that port-state, the EHCI Driver responds with a reset complete change set to one, a connect change set to one and a connect status set to zero. This information is derived directly from the EHCI port register. This allows the hub driver to assume the device was disconnected during reset. It acknowledges the change bits and wait for the next change event. While the EHCI controller does not own the port, it simply remains in a state where the port reports no device connected. The device-connect evaluation circuitry of the companion HC activates and detects the device, the companion Driver detects the connection and enumerates the port.

When a port is routed to a companion HC, it remains under the control of the companion HC until the device is disconnected from the root port (ignoring for now the scenario where EHCI's CF-bit transitions from 1b to 0b). When a disconnect occurs, the disconnect event is detected by both the companion HC port control and the EHCI port ownership control. On the event, the port ownership is returned immediately to the EHCI controller. The companion HC stack detects the disconnect and acknowledges as it would in an ordinary standalone implementation. Subsequent connects is detected by the EHCI port register and the process repeats.
42.5.3.2.3 Example Port Routing State Machine

The following figure illustrates an example of how the port ownership should be managed. The following sections describe the entry conditions to each state.

![Port Owner Handoff State Machine Diagram]

**Figure 42-5. Port Owner Handoff State Machine**

42.5.3.2.3.1 EHCI HC Owner

Entry to this state occurs when one of the following events occur:

- When the EHCI HC's Configure Flag (CF) bit in the USB_CONFIGFLAG register transitions from zero to one. This signals the fact that the system has a host controller driver for the EHCI HC and that all ports in the USB 2.0 host controller must default route to the EHCI controller.
- When the port is owned by a companion HC and the device is disconnected from the port. The EHCI port routing control logic is notified of the disconnect, and returns port routing to the EHCI controller. The connection state of the companion HC goes immediately to the disconnected state (with appropriate side effect to connect change, enable and enable change). The companion HC driver acknowledges the disconnect by setting the connect status change bit to zero. This allows the companion HC's driver to interact with the port completely through the disconnect process.
- When system software writes zero to the PortOwner bit in the USB_PORTSC1 register. This allows software to take ownership of a port from a companion host controller. When this occurs, the routing logic to the companion HC effectively signals a disconnect to the companion HC's port status and control register.
42.5.3.2.3.2 **Companion HC Owner**

Entry to this state occurs whenever one of the following events occur:

- When the PortOwner field transitions from zero to one.
- When the HS-mode HC's Configure Flag (CF) is equal to zero.

On entry to this state, the routing logic allows the companion HC port register to detect a device connect. Normal port enumeration proceeds.

42.5.3.2.4 **Port Power**

The Port Power Control (PPC) bit in the USB_HCSPARAMS register indicates whether the USB 2.0 host controller has port power control (see [Host Controller Structural Parameters](#)).

When this bit is zero, then the host controller does not support software control of port power switches. When in this configuration, the port power is always available and the companion host controllers must implement functionality consistent with port power always on. When the PPC bit is one, then the host controller implementation includes port power switches. Each available switch has an output enable, which is referred to in this discussion as PortPowerOutputEnable (PPE). PPE is controlled based on the state of the combination bits PPC bit, EHCI Configured (CF)-bit and individual Port Power (PP) bits.

The following table describes the summary behavioral model.

<table>
<thead>
<tr>

1. CHC (Companion Host Controller).
2. EHC (EHCI Host Controller).
3. PPE (Port Power Enable). This bit actually turns on the port power switch (if one exists).

#### 42.5.3.2.5 Port Reporting Over-Current

Host controllers are by definition power providers on USB. Whether the ports are considered high- or low-powered is a platform implementation issue. Each EHCI USB_PORTSC1 register has an over-current status and over-current change bit.

The functionality of these bits are specified in the USB Specification Revision 2.0.

The over current detection and limiting logic usually resides outside the host controller logic. This logic may be associated with one or more ports. When this logic detects an over-current condition it is made available to both the companion and EHCI ports. The effect of an over-current status on a companion host controller port is beyond the scope of this document.

The over-current condition effects the following bits in the USB_PORTSC1 register on the EHCI port:

- **Over-current Active bits** are set to one. When the over-current condition goes away, the Over-current Active bit transitions from one to zero.
- **Over-current Change bits** are set to one. On every transition of the Over-current Active bit the host controller sets the Over-current Change bit to one. Software sets the Over-current Change bit to zero by writing one to this bit.
- **Port Enabled/Disabled bit** is set to zero. When this change bit gets set to one, then the Port Change Detect bit in the USB_USBSTS register is set to one.
- **Port Power (PP) bits** may optionally be set to zero. There is no requirement in USB that a power provider shut off power in an over current condition. It is sufficient to limit the current and leave power applied. When the Over-current Change bit transitions from zero to one, the host controller also sets the Port Change Detect bit in the USB_USBSTS register to one. In addition, if the Port Change Interrupt Enable bit in the USB_USBINTR register is one, then the host controller issues an interrupt to the system. Refer to Table 42-38 for summary behavior for over-current detection.
when the host controller is halted (suspended from a device component point of view).

### 42.5.3.3 Suspend/Resume-Host Operational Model

The EHCI host controller provides an equivalent suspend and resume model as that defined for individual ports in a USB 2.0 Hub.

Control mechanisms are provided to allow system software to suspend and resume individual ports. The mechanisms allow the individual ports to be resumed completely through software initiation. Other control mechanisms are provided to parameterize the host controller's response (or sensitivity) to external resume events. In this discussion, host-initiated, or software initiated resumes are called Resume Events/Actions. Bus-initiated resume events are called wake-up events. The classes of wake-up events are:

- Remote-wake-up enabled device asserts resume signaling. In similar kind to USB 2.0 Hubs, EHCI controllers must always respond to explicit device resume signaling and wake-up the system (if necessary).
- Port connect and disconnect and over-current events. Sensitivity to these events can be turned on or off by using the per-port control bits in the USB_PORTSC1 registers.

Selective suspend is a feature supported by every USB_PORTSC1 register. It is used to place specific ports into a suspend mode. This feature is used as a functional component for implementing the appropriate power management policy implemented in a particular operating system. When system software intends to suspend the entire bus, it should selectively suspend all enabled ports, then shut off the host controller by setting the Run/Stop bit in the USB_USBCMD register to zero. The EHCI sub-block can then be placed into a lower device state through the PCI power management interface (see Appendix A, Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com).

When a wake event occurs, the system resumes operation and system software eventually set the Run/Stop bit to one and resume the suspended ports. Software must not set the Run/Stop bit to one until it is confirmed that the clock to the host controller is stable. This is usually confirmed in a system implementation in that all of the clocks in the system are stable before the Arm platform is restarted. So, by definition, if software is running, clocks in the system are stable and the Run/Stop bit in the USB_USBCMD register can be set to one. Minimum system software delays are also defined in the PCI Power Management Specification. Refer to PCI Power Management Specification for more information.
42.5.3.3.1 Port Suspend/Resume

System software places individual ports into suspend mode by writing one into the appropriate USB_PORTSC1 Suspend bit. Software must only set the Suspend bit when the port is in the enabled state (Port Enabled bit is one) and the EHCI is the port owner (PortOwner bit is zero).

The host controller may evaluate the Suspend bit immediately or wait until a micro-frame or frame boundary occurs. If evaluated immediately, the port is not suspended until the current transaction (if one is executing) completes. Therefore, there may be several micro-frames of activity on the port until the host controller evaluates the Suspend bit. The host controller must evaluate the Suspend bit at least every frame boundary.

System software can initiate a resume on a selectively suspended port by writing one to the Force Port Resume bit. Software should not attempt to resume a port unless the port reports that it is in the suspended state (see Port Status & Control (USB_nPORTSC1)). If system software sets Force Port Resume bit to one when the port is not in the suspended state, the resulting behavior is undefined. In order to assure proper USB device operation, software must wait for at least 10 ms after a port indicates that it is suspended (Suspend bit is one) before initiating a port resume through the Force Port Resume bit. When Force Port Resume bit is one, the host controller sends resume signaling down the port. System software times the duration of the resume (nominally 20 ms) then sets the Force Port Resume bit to zero. When the host controller receives the write to transition Force Port Resume to zero, it completes the resume sequence as defined in the USB specification, and sets both the Force Port Resume and Suspend bits to zero. Software-initiated port resumes do not affect the Port Change Detect bit in the USB_USBSTS register nor do they cause an interrupt if the Port Change Interrupt Enable bit in the USB_USBINTR register is one. An external USB event may also initiate a resume. The wake events are defined above. When a wake event occurs on a suspended port, the resume signaling is detected by the port and the resume is reflected downstream within 100 μsec. The port's Force Port Resume bit is set to one and the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit in the USB_USBINTR register is one the host controller issues a hardware interrupt.

System software observes the resume event on the port, delays a port resume time (nominally 20 ms), then terminates the resume sequence by writing zero to the Force Port Resume bit in the port. The host controller receives the write of zero to Force Port Resume, terminates the resume sequence and sets Force Port Resume and Suspend port bits to zero. Software can determine that the port is enabled (not suspended) by sampling the USB_PORTSC1 register and observing that the Suspend and Force Port Resume bits are zero. Software must ensure that the host controller is running (that is HCHalted bit in the USB_USBSTS register is zero), before terminating a resume by writing zero to a
port's Force Port Resume bit. If HCHalted is one when Force Port Resume is set to zero, then SOFs do not occur down the enabled port and the device returns to suspend mode in a maximum of 10 msec.

The table below summarizes the wake-up events. Whenever a resume event is detected, the Port Change Detect bit in the USB_USBSTS register is set to one. If the Port Change Interrupt Enable bit is one in the USB_USBINTR register, the host controller generates an interrupt on the resume event. Software acknowledges the resume event interrupt by clearing the Port Change Detect status bit in the USB_USBSTS register.

42.5.3.4 Schedule Traversal Rules

The host controller executes transactions for devices using a simple, shared-memory schedule.

The schedule is comprised of a few data structures, organized into two distinct lists. The data structures are designed to provide the maximum flexibility required by USB, minimize memory traffic and hardware / software complexity.

System software maintains two schedules for the host controller: a periodic schedule and an asynchronous schedule. The root of the periodic schedule is the USB_PERIODICLISTBASE register (see Frame List Base Address (USB_nPERIODICLISTBASE))/ Device Address (USB_nDEVICEADDR). The USB_PERIODICLISTBASE register is the physical memory base address of the periodic frame list. The periodic frame list is an array of physical memory pointers. The objects referenced from the frame list must be valid schedule data structures as defined in Host Data Structures. In each micro-frame, if the periodic schedule is enabled (see Periodic scheduling threshold) then the host controller must execute from the periodic schedule before executing from the asynchronous schedule. It only executes from the asynchronous schedule after it encounters the end of the periodic schedule. The host controller traverses the periodic schedule by constructing an array offset reference from the USB_PERIODICLISTBASE and the USB_FRINDEX registers (see the following figure). It fetches the element and begins traversing the graph of linked schedule data structures.

The end of the periodic schedule is identified by a next link pointer of a schedule data structure having its T-bit set to one. When the host controller encounters a T-Bit set to one during a horizontal traversal of the periodic list, it interprets this as an End-Of-Periodic-List mark. This causes the host controller to cease working on the periodic schedule and transitions immediately to traversing the asynchronous schedule. After the transition, the host controller executes from the asynchronous schedule until the end of the micro-frame.

The following figure illustrates the derivation of pointer into frame list array.
When the host controller determines that it is the time to execute from the asynchronous list, it uses the operational register USB_ASYNCLISTADDR to access the asynchronous schedule, see the figure below.

Figure 42-6. Derivation of Pointer into Frame List Array

The USB_ASYNCLISTADDR register contains a physical memory pointer to the next queue head. When the host controller makes a transition to executing the asynchronous schedule, it begins by reading the queue head referenced by the USB_ASYNCLISTADDR register. Software must set queue head horizontal pointer T-bits to zero for queue heads in the asynchronous schedule. See Asynchronous Schedule for complete operational details.

Figure 42-7. General Format of Asynchronous Schedule List
42.5.3.4.1 Example - Preserving Micro-Frame Integrity

One of the requirements of a USB host controller is to maintain Frame Integrity. This means that the HC must preserve the micro-frame boundaries.

For example, SOF packets must be generated on time (within the specified allowable jitter), and High-speed EOF1,2 thresholds must be enforced. The end of micro-frame timing points EOF1 and EOF2 are clearly defined in the USB Specification Revision 2.0. One implication of this responsibility is that the HC must ensure that it does not start transactions that do not complete before the end of the micro-frame. More precisely, no transactions should be started by the host controller, which do not complete in their entirety before the EOF1 point. In order to enforce this rule, the host controller must check each transaction before it starts to ensure that it completes before the end of the micro-frame.

So, what exactly needs to be involved in this check? Fundamentally, the transaction data payload, plus bit stuffing, plus transaction overhead must be taken into consideration. It is possible to be extremely accurate on how much time the next transaction takes. Take OUTs for an example. The host controller must fetch all of the OUT data from memory in order to send it onto the USB bus. A host controller implementation could pre-fetch all of the OUT data, and pre-compute the actual number of bits in the token and data packets. In addition, the system knows the depth of the target endpoint, so it could closely estimate turnaround time for handshake. In addition, the host controller knows the size of a handshake packet. Pre-computing effects of bit stuffing and summing up the other overhead numbers can allow the host controller to know exactly whether there is enough bus time, before EOF1 to complete the OUT transaction. To accomplish this particular approach takes an inordinate amount of time and hardware complexity.

The alternative is to make a reasonable guess whether the next transaction can be started. An example approximation algorithm is described below. This example algorithm relies on the EHCI policy that periodic transactions are scheduled first in the micro-frame. It is a reasonable assumption that software never over-commits the micro-frame to periodic transactions greater than the specification allowable 80%. In the available remaining 20% bandwidth, the host controller has some ability (in this example) to decide whether or not to execute a transaction. The result of this algorithm is that sometimes, under some circumstances a transaction is not executed that could have been executed. However, under all circumstances, a transaction is never started unless there is enough time in the frame to complete the transaction.

42.5.3.4.1.1 Transaction Fit - A Best-Fit Approximation Algorithm

A curve is calculated which represents the latest start time for every packet size, at which software schedules the start of a periodic transaction.
This curve is the 80% bandwidth curve. Another curve is calculated which is the absolute, latest permitted start time for every packet size. This curve represents the absolute latest time, that a transaction of each packet size can be started and completed, in the micro-frame. A plot of these two curves are illustrated in Figure 42-8. The plot Y-axis represents the number of byte-times left in a frame.

The space between the 80% and the Last Start plots is bandwidth reclamation area. In this algorithm the host controller may skip transactions during this time if it is prudent.

The Best-Fit Approximation method plots a function \( f(x) \) between the 80% and Last Start curves. The function \( f(x) \) adds a constant to every transaction's maximum packet size and the result compared with the number of bytes left in the frame. The constant represents an approximation of the effects of bit stuffing and protocol overhead. The host controller starts transactions whose results land above the function curve. The host controller will not start transactions whose results land below the function curve.

The following figure illustrates the Best-Fit Approximation.

![Figure 42-8. Best Fit Approximation](image)

The LastStart line was calculated in this example to assume the absolute worst-case bus overhead per transaction. The particular transaction used is a start-split, zero-length OUT transaction with a handshake. Summaries of the component parts are listed in the table below. The component times were derived from the protocol timings defined in the USB Specification Revision 2.0.

</tbody>
</table>

The exact details of the function \( f(x) \) are up to the particular implementation. However, it should be obvious that the goal is to minimize the area under the curve between the approximation function and the Last Start curve, without dipping below the LastStart line, while at the same time keeping the check as simple as possible for hardware implementation. The \( f(x) \) in Figure 42-8 was constructed using the following pseudo-code test on each transaction size data point. This algorithm assumes that the host controller keeps track of the remaining bits in the frame.

```
Algorithm CheckTransactionWillFit (MaximumPacketSize, HC_BytesLeftInFrame)
Begin
  Local Temp = MaximumPacketSize + 192
  Local rvalue = TRUE
  If MaximumPacketSize >= 128 then
    Temp += 128
  End If
  If Temp > HC_BytesLeftInFrame then
    Rvalue = FALSE
  End If
Return rvalue
End
```

This algorithm takes two inputs, the current maximum packet size of the transaction and the hardware counter of the number of bytes left in the current micro-frame. It unconditionally adds a simple constant of 192 to the maximum packet size to account for a first-order effect of transaction overhead and bit stuffing. If the transaction size is greater than or equal to 128 bytes, then an additional constant of 128 is added to the running sum to account for the additional worst-case bit stuffing of payloads larger than 128. An inflection point was inserted at 128 because the \( f(x) \) plot was getting close to the LastStart line.
42.5.3.5 Periodic Schedule Frame Boundaries vs Bus Frame Boundaries

The USB Specification Revision 2.0 requires that the frame boundaries (SOF frame number changes) of the high-speed bus and the full- and low-speed bus(s) below USB 2.0 Hubs be strictly aligned.

Super-imposed on this requirement is that USB 2.0 Hubs manage full- and low-speed transactions through a micro-frame pipeline (see start- (SS) and complete- (CS) splits illustrated in the following figure). A simple, direct projection of the frame boundary model into the host controller interface schedule architecture creates tension (complexity for both hardware and software) between the frame boundaries and the scheduling mechanisms required to service the full- and low-speed transaction translator periodic pipelines.

![Frame Boundary Relationship between HS bus and FS/LS Bus](image)

The simple projection, as the above figure illustrates, introduces frame-boundary wrap conditions for scheduling on both the beginning and end of a frame. In order to reduce the complexity for hardware and software, the host controller is required to implement one micro-frame phase shift for its view of frame boundaries. The phase shift eliminates the beginning of frame and frame-wrap scheduling boundary conditions.

The implementation of this phase shift requires that the host controller use one register value for accessing the periodic frame list and another value for the frame number value included in the SOF token. These two values are separate, but tightly coupled. The periodic frame list is accessed through the Frame List Index Register (USB_FRINDEX) documented in USB Frame Index (USB_nFRINDEX) and initially illustrated in Schedule Traversal Rules. Bits FRINDEX[2:0], represent the micro-frame number. The SOF value is coupled to the value of FRINDEX[13:3]. Both FRINDEX[13:3] and the SOF value are increment based on FRINDEX[2:0]. It is required that the SOF value be delayed from the FRINDEX value by one micro-frame. The one micro-frame delay yields host controller periodic schedule and bus frame boundary relationship as illustrated in the following figure. This adjustment allows software to trivially schedule the periodic start and
complete-split transactions for full-and low-speed periodic endpoints, using the natural alignment of the periodic schedule interface. The reasons for selecting this phase-shift are beyond the scope of this specification.

The following figure illustrates how periodic schedule data structures relate to schedule frame boundaries and bus frame boundaries. To aid the presentation, two terms are defined: The host controller's view of the 1 msec boundaries is called H-Frames. The high-speed bus's view of the 1 msec boundaries is called B-Frames.

![Figure 42-10. Relationship of Periodic Schedule Frame Boundaries to Bus Frame Boundaries](image)

H-Frame boundaries for the host controller correspond to increments of FRINDEX[13:3]. Micro-frame numbers for the H-Frame are tracked by FRINDEX[2:0]. B-Frame boundaries are visible on the high-speed bus through changes in the SOF token's frame number. Micro-frame numbers on the high-speed bus are only derived from the SOF token's frame number (that is the high-speed bus sees eight SOFs with the same frame number value). H-Frames and B-Frames have the fixed relationship (that is B-Frames lag H-Frames by one micro-frame time) illustrated in the figure above. The host controller's periodic schedule is naturally aligned to H-Frames. Software schedules transactions for full- and low-speed periodic endpoints relative the H-Frames. The result is these transactions execute on the high-speed bus at exactly the right time for the USB 2.0 Hub periodic pipeline. As described in USB Frame Index (USB_nFRINDEX), the SOF Value can be implemented as a shadow register (in this example, called SOFV), which lags the FRINDEX register bits [13:3] by one micro-frame count. This lag behavior can be accomplished by incrementing FRINDEX[13:3] based on carry-out on the 7 to 0 increment of FRINDEX[2:0] and incrementing SOFV based on the transition of 0 to 1 of FRINDEX[2:0].
Software is allowed to write to FRINDEX. **USB Frame Index (USB_nFRINDEX)** provides the requirements that software should adhere when writing a new value in FRINDEX.

The table below illustrates the required relationship between the value of FRINDEX and the value of SOFV.

**42.5.3.6 Periodic Schedule**

The periodic schedule traversal is enabled or disabled through the Periodic Schedule Enable bit in the USB_USBCMD register. If the Periodic Schedule Enable bit is set to zero, then the host controller simply does not try to access the periodic frame list through the USB_PERIODICLISTBASE register. Likewise, when the Periodic Schedule Enable bit is one, then the host controller does use the USB_PERIODICLISTBASE register to traverse the periodic schedule.

The host controller will not react to modifications to the Periodic Schedule Enable immediately. In order to eliminate conflicts with split transactions, the host controller evaluates the Periodic Schedule Enable bit only when FRINDEX[2:0] is zero. System software must not disable the periodic schedule if the schedule contains an active split transaction work item that spans the 000b micro-frame. These work items must be removed from the schedule before the Periodic Schedule Enable bit is written to zero.

The Periodic Schedule Status bit in the USB_USBSTS register indicates status of the periodic schedule. System software enables (or disables) the periodic schedule by writing one (or zero) to the Periodic Schedule Enable bit in the USB_USBCMD register. Software then can poll the Periodic Schedule Status bit to determine when the periodic
schedule has made the desired transition. Software must not modify the Periodic Schedule Enable bit unless the value of the Periodic Schedule Enable bit equals that of the Periodic Schedule Status bit.

The periodic schedule is used to manage all isochronous and interrupt transfer streams. The base of the periodic schedule is the periodic frame list. Software links schedule data structures to the periodic frame list to produce a graph of scheduled data structures. The graph represents an appropriate sequence of transactions.

The following figure illustrates isochronous transfers (using iTDs and siTDs) with a period of one are linked directly to the periodic frame list. Interrupt transfers (are managed with queue heads) and isochronous streams with periods other than one are linked following the period-one iTD/siTDs. Interrupt queue heads are linked into the frame list ordered by poll rate. Longer poll rates are linked first (for example, closest to the periodic frame list), followed by shorter poll rates, with queue heads with a poll rate of one, on the very end.

![Figure 42-11. Example Periodic Schedule](image_url)
42.5.3.7 Managing Isochronous Transfers Using iTDs

The structure of an iTD is presented in Isochronous (High-Speed) Transfer Descriptor (iTD). The four distinct sections to an iTD:

- The first field is the Next Link Pointer. This field is for schedule linkage purposes only.
- Transaction description array. This area is an eight-element array. Each element represents control and status information for one micro-frame's worth of transactions for a single high-speed isochronous endpoint.
- The buffer page pointer array is a 7-element array of physical memory pointers to data buffers. These are 4 K aligned pointers to physical memory.
- Endpoint capabilities. This area utilizes the unused low-order 12 bits of the buffer page pointer array. The fields in this area are used across all transactions executed for this iTD, including endpoint addressing, transfer direction, maximum packet size and high-bandwidth multiplier.

42.5.3.7.1 Host Controller Operational Model for iTDs

The host controller uses FRINDEX register bits [12:3] to index into the periodic frame list. This means that the host controller visits each frame list element eight consecutive times before incrementing to the next periodic frame list element. Each iTD contains eight transaction descriptions, which map directly to FRINDEX register bits [2:0]. Therefore, each transaction descriptor corresponds to one micro-frame. Each iTD can span 8 micro-frames worth of transactions.

When the host controller fetches an iTD, it uses FRINDEX register bits [2:0] to index into the transaction description array.

If the active bit in the Status field of the indexed transaction description is set to zero, the host controller ignores the iTD and follows the Next pointer to the next schedule data structure.

When the indexed active bit is one, the host controller continues to parse the iTD. It stores the indexed transaction description and the general endpoint information (device address, endpoint number, maximum packet size, and so on.). It also uses the Page Select (PG) field to index the buffer pointer array, storing the selected buffer pointer and the next sequential buffer pointer. For example, if PG field is 0, then the host controller stores Page 0 and Page 1.
The host controller constructs a physical data buffer address by concatenating the current buffer pointer (as selected using the current transaction description's PG field) and the transaction description's Transaction Offset field. The host controller uses the endpoint addressing information and I/O-bit to execute a transaction to the appropriate endpoint. When the transaction is complete, the host controller clears the active bit and writes back any additional status information to the Status field in the currently selected transaction description.

The data buffer associated with the iTD must be virtually contiguous memory. Seven page pointers are provided to support eight high-bandwidth transactions regardless of the starting packet's offset alignment into the first page. A starting buffer pointer (physical memory address) is constructed by concatenating the page pointer (for example, page 0 pointer) selected by the active transaction descriptions' PG (for example, value: 00B) field with the transaction offset field. As the transaction moves data, the host controller must detect when an increment of the current buffer pointer crosses a page boundary. When this occurs the host controller simply replaces the current buffer pointer's page portion with the next page pointer (for example, page 1 pointer) and continues to move data. The size of each bus transaction is determined by the value in the Maximum Packet Size field. An iTD supports high-bandwidth pipes through the Mult (multiplier) field. When the Mult field is 1, 2, or 3, the host controller executes the specified number of Maximum Packet sized bus transactions for the endpoint in the current micro-frame. In other words, the Mult field represents a transaction count for the endpoint in the current micro-frame. If the Mult field is zero, the operation of the host controller is undefined. The transfer description is used to service all transactions indicated by the Mult field.

For OUT transfers, the value of the Transaction X Length field represents the total bytes to be sent during the micro-frame. The Mult field must be set by software to be consistent with Transaction X Length and Maximum Packet Size. The host controller sends the bytes in Maximum Packet Size'd portions. After each transaction, the host controller decrements its local copy of Transaction X Length by Maximum Packet Size. The number of bytes the host controller sends is always Maximum Packet Size or Transaction X Length, whichever is less. The host controller advances the transfer state in the transfer description, updates the appropriate record in the iTD and moves to the next schedule data structure. The maximum sized transaction supported is 3 x 1024 bytes.

For IN transfers, the host controller issues Mult transactions. It is assumed that software has properly initialized the iTD to accommodate all of the possible data. During each IN transaction, the host controller must use Maximum Packet Size to detect packet babble errors. The host controller keeps the sum of bytes received in the Transaction X Length field. After all transactions for the endpoint have completed for the micro-frame, Transaction X Length contains the total bytes received. If the final value of Transaction X Length is less than the value of Maximum Packet Size, then less data than was allowed for was received from the associated endpoint. This short packet condition does not set
the USBINT bit in the USB_USBSTS register to one. The host controller will not detect this condition. If the device sends more than Transaction X Length or Maximum Packet Size bytes (whichever is less), then the host controller sets the Babble Detected bit to one and set the Active bit to zero. Note, that the host controller is not required to update the iTD field Transaction X Length in this error scenario. If the Mult field is greater than one, then the host controller automatically executes the value of Mult transactions. The host controller will not execute all Mult transactions if:

- The endpoint is an OUT and Transaction X Length goes to zero before all the Mult transactions have executed (ran out of data), or
- The endpoint is an IN and the endpoint delivers a short packet, or an error occurs on a transaction before Mult transactions have been executed. The end of micro-frame may occur before all of the transaction opportunities have been executed. When this happens, the transfer state of the transfer description is advanced to reflect the progress that was made, the result written back to the iTD and the host controller proceeds to processing the next micro-frame. Refer to Appendix D for a table summary of the host controller required behavior for all the high-bandwidth transaction cases.

### 42.5.3.7.2 Software Operational Model for iTDs

A client buffer request to an isochronous endpoint may span 1 to N micro-frames. When N is larger than one, system software may have to use multiple iTDs to read or write data with the buffer (if N is larger than eight, it must use more than one iTD).

The following figure illustrates the simple model of how a client buffer is mapped by system software to the periodic schedule (that is the periodic frame list and a set of iTDs). On the right is the client description of its request. The description includes a buffer base address plus additional annotations to identify which portions of the buffer should be used with each bus transaction. In the middle is the iTD data structures used by the system software to service the client request. Each iTD can be initialized to service up to 24 transactions, organized into eight groups of up to three transactions each. Each group maps to one micro-frame's worth of transactions. The EHCI controller does not provide per-transaction results within a micro-frame. It treats the per-micro-frame transactions as a single logical transfer. On the left is the host controller's frame list. System software establishes references from the appropriate locations in the frame list to each of the appropriate iTDs. If the buffer is large, then system software can use a small set of iTDs to service the entire buffer. System software can activate the transaction description records (contained in each iTD) in any pattern required for the particular data stream.
As noted above, the client request includes a pointer to the base of the buffer and offsets into the buffer to annotate which buffer sections are to be used on each bus transaction that occurs on this endpoint. System software must initialize each transaction description in an iTD to ensure it uses the correct portion of the client buffer. For example, for each transaction description, the PG field is set to index the correct physical buffer page pointer and the Transaction Offset field is set relative to the correct buffer pointer page (for example, the same one referenced by the PG field). When the host controller executes a transaction it selects a transaction description record based on FRINDEX[2:0]. It then uses the current Page Buffer Pointer (as selected by the PG field) and concatenates to the transaction offset field. The result is a starting buffer address for the transaction. As the host controller moves data for the transaction, it must watch for a page wrap condition and properly advance to the next available Page Buffer Pointer. System software must not use the Page 6 buffer pointer in a transaction description where the length of the transfer wraps a page boundary. Doing so yields undefined behavior. The host controller hardware is not required to ‘alias’ the page selector to Page zero. USB 2.0 isochronous.
endpoints can specify a period greater than one. Software can achieve the appropriate scheduling by linking iTDs into the appropriate frames (relative to the frame list) and by setting appropriate transaction description elements active bits to one.

### 42.5.3.7.2.1 Periodic scheduling threshold

The Isochronous Scheduling Threshold field in the USB_HCCPARAMS capability register is an indicator to system software as to how the host controller pre-fetches and effectively caches schedule data structures.

It is used by system software when adding isochronous work items to the periodic schedule. The value of this field indicates to system software the minimum distance it can update isochronous data (relative to the current location of the host controller execution in the periodic list) and still have the host controller process them.

The iTD and siTD data structures each describe 8 micro-frames worth of transactions. The host controller is allowed to cache one (or more) of these data structures in order to reduce memory traffic. Three basic caching models that account for the fact the isochronous data structures span 8 micro-frames. The three caching models are: no caching, micro-frame caching and frame caching.

When software is adding new isochronous transactions to the schedule, it always performs a read of the USB_FRINDEX register to determine the current frame and micro-frame the host controller is currently executing. Of course, there is no information about where in the micro-frame the host controller is, so a constant uncertainty-factor of one micro-frame has to be assumed. Combining the knowledge of where the host controller is executing with the knowledge of the caching model allows the definition of simple algorithms for how closely software can reliably work to the executing host controller.

No caching is indicated with a value of zero in the Isochronous Scheduling Threshold field. The host controller may pre-fetch data structures during a periodic schedule traversal (per micro-frame) but always dumps any accumulated schedule state at the end of the micro-frame. At the appropriate time relative to the beginning of every micro-frame, the host controller always begins schedule traversal from the frame list. Software can use the value of the USB_FRINDEX register (plus the constant 1 uncertainty-factor) to determine the approximate position of the executing host controller. When no caching is selected, software can add an isochronous transaction as near as 2 micro-frames in front of the current executing position of the host controller.

Frame caching is indicated with a non-zero value in bit [7] of the Isochronous Scheduling Threshold field. In the frame-caching model, system software assumes that the host controller caches one (or more) isochronous data structures for an entire frame (8 micro-frames). Software uses the value of the USB_FRINDEX register (plus the constant 1
uncertainty) to determine the current micro-frame/frame (assume modulo 8 arithmetic in
adding the constant 1 to the micro-frame number). For any current frame N, if the current
micro-frame is 0 to 6, then software can safely add isochronous transactions to Frame N
+ 1. If the current micro-frame is 7, then software can add isochronous transactions to
Frame N + 2.

Micro-frame caching is indicated with a non-zero value in the least-significant 3 bits of
the Isochronous Scheduling Threshold field. System software assumes the host controller
caches one or more periodic data structures for the number of micro-frames indicated in
the Isochronous Scheduling Threshold field. For example, if the count value were 2, then
the host controller keeps a window of 2 micro-frames worth of state (current micro-
frame, plus the next) on-chip. On each micro-frame boundary, the host controller releases
the current micro-frame state and begins accumulating the next micro-frame state.

42.5.3.8 Asynchronous Schedule

The Asynchronous schedule traversal is enabled or disabled through the Asynchronous
Schedule Enable bit in the USB_USBCMD register.

If the Asynchronous Schedule Enable bit is set to zero, then the host controller simply
does not try to access the asynchronous schedule through the USB_ASYNCLISTADDR
register. Likewise, when the Asynchronous Schedule Enable bit is one, then the host
controller does use the USB_ASYNCLISTADDR register to traverse the asynchronous
schedule. Modifications to the Asynchronous Schedule Enable bit are not necessarily
immediate. Rather the new value of the bit is taken into consideration the next time the
host controller needs to use the value of the USB_ASYNCLISTADDR register to get the
next queue head.

The Asynchronous Schedule Status bit in the USB_USBSTS register indicates status of
the asynchronous schedule. System software enables (or disables) the asynchronous
schedule by writing one (or zero) to the Asynchronous Schedule Enable bit in the
USB_USBCMD register. Software then can poll the Asynchronous Schedule Status bit to
determine when the asynchronous schedule has made the desired transition. Software
must not modify the Asynchronous Schedule Enable bit unless the value of the
Asynchronous Schedule Enable bit equals that of the Asynchronous Schedule Status bit.

The asynchronous schedule is used to manage all Control and Bulk transfers. Control and
Bulk transfers are managed using queue head data structures. The asynchronous schedule
is based at the USB_ASYNCLISTADDR register. The default value of the
USB_ASYNCLISTADDR register after reset is undefined and the schedule is disabled
when the Asynchronous Schedule Enable bit is zero.
Software may only write this register with defined results when the schedule is disabled. For example, Asynchronous Schedule Enable bit in the USB_USBCMD and the Asynchronous Schedule Status bit in the USB_USBSTS register are zero. System software enables execution from the asynchronous schedule by writing a valid memory address (of a queue head) into this register. Then software enables the asynchronous schedule by setting the Asynchronous Schedule Enable bit to one. The asynchronous schedule is actually enabled when the Asynchronous Schedule Status bit is one.

When the host controller begins servicing the asynchronous schedule, it begins by using the value of the USB_ASYNCLISTADDR register. It reads the first referenced data structure and begins executing transactions and traversing the linked list as appropriate. When the host controller completes processing the asynchronous schedule, it retains the value of the last accessed queue head's horizontal pointer in the USB_ASYNCLISTADDR register. Next time the asynchronous schedule is accessed, this is the first data structure that is serviced. This provides round-robin fairness for processing the asynchronous schedule.

A host controller completes processing the asynchronous schedule when one of the following events occur:

- The end of a micro-frame occurs.
- The host controller detects an empty list condition (see Empty Asynchronous Schedule Detection)
- The schedule has been disabled through the Asynchronous Schedule Enable bit in the USB_USBCMD register.

The queue heads in the asynchronous list are linked into a simple circular list as shown in Figure 42-7. Queue head data structures are the only valid data structures that may be linked into the asynchronous schedule. An isochronous transfer descriptor (iTD or siTD) in the asynchronous schedule yields undefined results.

The maximum packet size field in a queue head is sized to accommodate the use of this data structure for all non-isochronous transfer types. The USB Specification, Revision 2.0 specifies the maximum packet sizes for all transfer types and transfer speeds. System software should always parameterize the queue head data structures according to the core specification requirements.

### 42.5.3.8.1 Adding Queue Heads to Asynchronous Schedule

This is a software requirement section.

There are two independent events for adding queue heads to the asynchronous schedule. The first is the initial activation of the asynchronous list. The second is inserting a new queue head into an activated asynchronous list.
Activation of the list is simple. System software writes the physical memory address of a queue head into the USB_ASYNCLISTADDR register, then enables the list by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to one.

When inserting a queue head into an active list, software must ensure that the schedule is always coherent from the host controllers' point of view. This means that the system software must ensure that all queue head pointer fields are valid. For example, qTD pointers have T-Bits set to one or reference valid qTDs and the Horizontal Pointer references a valid queue head data structure. The following algorithm represents the functional requirements:

```c
InsertQueueHead (pQHeadCurrent, pQueueHeadNew)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadCurrent is a pointer to a queue head that is
-- already in the active list
-- pQueueHeadNew is a pointer to the queue head to be added
--
-- This algorithm links a new queue head into a existing
-- list
--
   pQueueHeadNew.HorizontalPointer = pQueueHeadCurrent.HorizontalPointer
   pQueueHeadCurrent.HorizontalPointer = physicalAddressOf(pQueueHeadNew)
End InsertQueueHead
```

### 42.5.3.8.2 Removing Queue Heads from Asynchronous Schedule

This is a software requirement section.

There are two independent events for removing queue heads from the asynchronous schedule. The first is shutting down (deactivating) the asynchronous list. The second is extracting a single queue head from an activated list.

Software deactivates the asynchronous schedule by setting the Asynchronous Schedule Enable bit in the USB_USBCMD register to zero. Software can determine when the list is idle when the Asynchronous Schedule Status bit in the USB_USBSTS register is zero. The normal mode of operation is that software removes queue heads from the asynchronous schedule without shutting it down. Software must not remove an active queue head from the schedule. Software should first deactivate all active qTDs, wait for the queue head to go inactive, then remove the queue head from the asynchronous list. Software removes a queue head from the asynchronous list through the following algorithm. As illustrated, the unlinking is quite easy. Software merely must ensure all of the link pointers reachable by the host controller are kept consistent.

```c
UnlinkQueueHead (pQHeadPrevious, pQueueHeadToUnlink, pQHeadNext)
--
-- Requirement: all inputs must be properly initialized.
--
-- pQHeadPrevious is a pointer to a queue head that
-- references the queue head to remove
-- pQHeadToUnlink is a pointer to the queue head to be
```
If software removes the queue head with the H-bit set to one, it must select another queue head still linked into the schedule and set its H-bit to one. This should be completed before removing the queue head. The requirement is that software keep one queue head in the asynchronous schedule, with its H-bit set to one. At the point software has removed one or more queue heads from the asynchronous schedule, it is unknown whether the host controller has a cached pointer to them. Similarly, it is unknown how long the host controller might retain the cached information, as it is implementation dependent and may be affected by the actual dynamics of the schedule load. Therefore, once software has removed a queue head from the asynchronous list, it must retain the coherency of the queue head (link pointers, and so on). It cannot disturb the removed queue heads until it knows that the host controller does not have a local copy of a pointer to any of the removed data structures.

The method software uses to determine when it is safe to modify a removed queue head is to handshake with the host controller. The handshake mechanism allows software to remove items from the asynchronous schedule, then execute a simple, lightweight handshake that is used by software as a key that it can free (or reuse) the memory associated the data structures it has removed from the asynchronous schedule.

The handshake is implemented with three bits in the host controller. The first bit is a command bit (Interrupt on Async Advance Doorbell bit in the USB_USBCMD register) that allows software to inform the host controller that something has been removed from its asynchronous schedule. The second bit is a status bit (Interrupt on Async Advance bit in the USB_USBSTS register) that the host controller sets after it has released all on-chip state that may potentially reference one of the data structures just removed. When the host controller sets this status bit to one, it also sets the command bit to zero. The third bit is an interrupt enable (Interrupt on Async Advance bit in the USB_USBINTR register) that is matched with the status bit. If the status bit is one and the interrupt enable bit is one, then the host controller asserts a hardware interrupt.

The figure below illustrates a general example. In this example, consecutive queue heads (B and C) are unlinked from the schedule using the algorithm above. Before the unlink operation, the host controller has a copy of queue head A.
The unlink algorithm requires that as software unlinks each queue head, the unlinked queue head is loaded with the address of a queue head that remains in the asynchronous schedule.

When the host controller observes that doorbell bit being set to one, it makes a note of the local reachable schedule information. In this example, the local reachable schedule information includes both queue heads (A and B). It is sufficient that the host controller can set the status bit (and clear the doorbell bit) as soon as it has traversed beyond current reachable schedule information (that is traversed beyond queue head (B) in this example). The following figure illustrates the generic queue head unlink scenario.

![Diagram showing queue head unlink scenario]

*Figure 42-13. Generic Queue Head Unlink Scenario*

Alternatively, a host controller implementation is allowed to traverse the entire asynchronous schedule list (for example, observed the head of the queue (twice)) before setting the Advance on Async status bit to one.

Software may re-use the memory associated with the removed queue heads after it observes the Interrupt on Async Advance status bit is set to one, following assertion of the doorbell. Software should acknowledge the Interrupt on Async Advance status as indicated in the USB_USBSTS register, before using the doorbell handshake again.

### 42.5.3.8.3 Empty Asynchronous Schedule Detection

The Enhanced Host Controller Interface uses two bits to detect when the asynchronous schedule is empty.
The queue head data structure (see Table 42-26) defines an *H-bit* in the queue head, which allows software to mark a queue head as being the *head* of the reclaim list. The Enhanced Host Controller Interface also keeps a 1-bit flag in the USB_USBSTS register (*Reclamation*) that is set to zero when the Enhanced Interface Host Controller observes a queue head with the H-bit set to one. The reclamation flag in the status register is set to one when any USB transaction from the asynchronous schedule is executed (or whenever the asynchronous schedule starts, see Asynchronous schedule traversal: *Start Event*).

If the Enhanced Host Controller Interface ever encounters an *H-bit* of one and a *Reclamation* bit of zero, the EHCI controller simply stops traversal of the asynchronous schedule.

An example illustrating the H-bit in a schedule is shown in the following figure.

**Figure 42-14. Asynchronous Schedule List w/Annotation to Mark Head of List**

Software must ensure there is at most one queue head with the *H-bit* set to one, and that it is always coherent with respect to the schedule.

### 42.5.3.8.4 Restarting Asynchronous Schedule Before EOF

There are many situations where the host controller will detect an empty list *long* before the end of the micro-frame.

It is important to remember that under many circumstances the schedule traversal has stopped due to Nak/Nyet responses from all endpoints.

An example of particular interest is when a start-split for a bulk endpoint occurs early in the micro-frame. Given the EHCI simple traversal rules, the complete-split for that transaction may Nak/Nyet out very quickly. If it is the only item in the schedule, then the host controller ceases traversal of the Asynchronous schedule very early in the micro-frame. In order to provide reasonable service to this endpoint, the host controller should issue the complete-split before the end of the current micro-frame, instead of waiting.
until the next micro-frame. When the reason for host controller idling asynchronous schedule traversal is because of empty list detection, it is mandatory the host controller implement a 'waking' method to resume traversal of the asynchronous schedule. An example method is described below.

42.5.3.8.4.1  Example Method for Restarting Asynchronous Schedule Traversal

The reason for idling the host controller when the list is empty is to keep the host controller from unnecessarily occupying too much memory bandwidth. The question is: how long should the host controller stay idle before restarting?

The answer in this example is based on deriving a manifest constant, which is the amount of time the host controller will stay idle before restarting traversal. In this example, the manifest constant is called AsyncSchedSleepTime, and has a value of 10 μsec. The value is derived based on the analysis in Example Derivation for AsyncSchedSleepTime, The traversal algorithm is simple:

- Traverse the Asynchronous schedule until the either an End-Of-micro-Frame event occurs, or an empty list is detected. If the event is an End-of-micro-Frame, go attempt to traverse the Periodic schedule. If the event is an empty list, then set a sleep timer and go to a schedule sleep state.
- When the sleep timer expires, set working context to the Asynchronous Schedule start condition and go to schedule active state. The start context allows the HC to reload Nakcnt fields, and so on. So the HC has a chance to run for more than one iteration through the schedule.

This process simply repeats itself each micro-frame. The figure below illustrates a sample state machine to manage the active and sleep states of the Asynchronous Schedule traversal policy. There are three states: Actively traversing the Asynchronous schedule, Sleeping, and Not Active. The last two are similar in terms of interaction with the Asynchronous schedule, but the Not Active state means that the host controller is busy with the Periodic schedule or the Asynchronous schedule is not enabled. The Sleeping state is specifically a special state where the host controller is just waiting for a period of time before resuming execution of the Asynchronous schedule.
Figure 42-15. Example State Machine for Managing Asynchronous Schedule Traversal

The actions referred to in the figure above are defined in the following table.

Table 42-41. Asynchronous Schedule SM Transition Actions

<table>
<thead>
<tr>
<th>Action</th>
<th>Action Description Label</th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>On detection of the empty list, the host controller sets the AsynchronousTraversalSleepTimer to AsyncSchedSleepTime.</td>
</tr>
<tr>
<td>B</td>
<td>When the AsynchronousTraversalSleepTimer expires, the host controller sets the Reclamation bit in the USBSTS register to one and moves the Nak Counter reload state machine to WaitForListHead (see Nak Count Reload Control).</td>
</tr>
<tr>
<td>C</td>
<td>The host controller cancels the sleep timer (AsynchronousTraversalSleepTimer).</td>
</tr>
</tbody>
</table>

42.5.3.8.4.2 Async Sched Not Active

This is the initial state of the traversal state machine after a host controller reset. The traversal state machine does not leave this state when the Asynchronous Schedule Enable bit in the USB_USBCMD register is zero.

This state is entered from Async Sched Active or Async Sched Sleeping states when the end-of-micro-frame event is detected.

42.5.3.8.4.3 Async Sched Active

This state is entered from the Async Sched Not Active state when the periodic schedule is not active. It is also entered from the Async Sched Sleeping states when the AsyncrhonousTraversalSleepTimer expires. On every transition into this state, the host controller sets the Reclamation bit in the USB_USBSTS register to one.
While in this state, the host controller continually traverses the asynchronous schedule until either the end of micro-frame or an empty list condition is detected.

### 42.5.3.8.4.4 Async Sched Sleeping

The state is entered from the Async Sched Active state when a schedule empty condition is detected. On entry to this state, the host controller sets the `AsynchronousTraversalSleepTimer` to `AsyncSchedSleepTime`.

### 42.5.3.8.4.5 Example Derivation for `AsyncSchedSleepTime`

The derivation is based on analysis of what work the host controller could be doing next. It assumes the host controller does not keep any state about what work is possibly pending in the asynchronous schedule. The schedule could contain any mix of the possible combinations of high- full- or low-speed control and bulk requests.

The table below summarizes some of the typical 'next transactions' that could be in the schedule, and the amount of time (for example `footprint`, or `wall clock`) the transaction takes to complete.

<table>
<thead>
<tr>
<th>Transaction Attributes</th>
<th>Footprint (time)</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Speed</td>
<td>Size</td>
<td>Type</td>
</tr>
<tr>
<td>HS</td>
<td>11.9 ms</td>
<td>Bulk</td>
</tr>
<tr>
<td>512</td>
<td>9.45 ms</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>FS</td>
<td>~50 ms</td>
<td></td>
</tr>
<tr>
<td>64</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>~12 ms</td>
<td></td>
</tr>
<tr>
<td>8</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

A `AsyncSchedSleepTime` value of 10 μs provides a reasonable relaxation of the system memory load and still provides a good level of service for the various transfer types and payload sizes. For example, say we detect an empty list after issuing a start-split for a 64-byte full-speed bulk request. Assuming this is the only thing in the list, the host controller gets the results of the full-speed transaction from the hub during the fifth complete-split request. If the full-speed transaction was an IN and it nak'd, the 10 μs sleep period would allow the host controller to get the NAK results on the first complete-split.
42.5.3.8.5  Asynchronous schedule traversal: Start Event

Once the HC has idled itself through the empty schedule detection (Section 0), it will naturally activate and begin processing from the Periodic Schedule at the beginning of each micro-frame.

In addition, it may have idled itself early in a micro-frame. When this occurs (idles early in the micro-frame) the HC must occasionally re-activate during the micro-frame and traverse the asynchronous schedule to determine whether any progress can be made. The requirements and method for this restart are described in Restarting Asynchronous Schedule Before EOF. Asynchronous schedule Start Events are defined to be:

- Whenever the host controller transitions from the periodic schedule to the asynchronous schedule. If the periodic schedule is disabled and the asynchronous schedule is enabled, then the beginning of the micro-frame is equivalent to the transition from the periodic schedule, or
- The asynchronous schedule traversal restarts from a sleeping state (see Restarting Asynchronous Schedule Before EOF).

42.5.3.8.6  Reclamation Status Bit (USBSTS Register)

The operation of the empty asynchronous schedule detection feature (see Empty Asynchronous Schedule Detection) depends on the proper management of the Reclamation bit in the USB_USBSTS register. The host controller tests for an empty schedule just after it fetches a new queue head while traversing the asynchronous schedule (see Fetch Queue Head).

The host controller is required to set the Reclamation bit to one whenever an asynchronous schedule traversal Start Event, as documented in Asynchronous schedule traversal: Start Event, occurs. The Reclamation bit is also set to one whenever the host controller executes a transaction while traversing the asynchronous schedule (see Execute Transaction). The host controller sets the Reclamation bit to zero whenever it finds a queue head with its H-bit set to one. Software should only set a queue head's H-bit if the queue head is in the asynchronous schedule. If software sets the H-bit in an interrupt queue head to one, the resulting behavior is undefined. The host controller may set the Reclamation bit to zero when executing from the periodic schedule.

42.5.3.9  Operational Model for Nak Counter

This section describes the operational model for the NakCnt field defined in a queue head.
See Queue Head Initialization for more information. Software should not use this feature for interrupt queue heads. This rule is not required to be enforced by the host controller.

USB protocol has built-in flow control through the Nak response by a device. There are several scenarios, beyond the Ping feature, where an endpoint may naturally Nak or Nyet the majority of the time. An example is the host controller management of the split transaction protocol for control and bulk endpoints. All bulk endpoints (High- or Full-speed) are serviced through the same asynchronous schedule. The time between the Start-split transaction and the first Complete-split transaction could be very short (that is like when the endpoint is the only one in the asynchronous schedule). The hub NYETs (effectively Naks) the Complete-split transaction until the classic transaction is complete. This could result in the host controller thrashing memory, repeatedly fetching the queue head and executing the transaction to the Hub, which does not complete until after the transaction on the classic bus completes.

The two component fields in a queue head to support the throttling feature: a counter field (NakCnt), and a counter reload field (RL). NakCnt is used by the host controller as one of the criteria to determine whether or not to execute a transaction to the endpoint. The two operational modes associated with this counter:

- **Not Used-** This mode is set when the RL field is zero. The host controller ignores the NakCnt field for any execution of transactions through a queue head with an RL field of zero. Software must use this selection for interrupt endpoints.
- **Nak Throttle Mode-** This mode is selected when the RL field is non-zero. In this mode, the value in the NakCnt field represents the maximum number of Nak or Nyet responses the host controller tolerates on each endpoint. In this mode, the HC decrements the NakCnt field based on the token/handshake criteria listed in the table below. The host controller must reload NakCnt when the endpoint successfully moves data (for example, policy to reward device for moving data).

The following table describes the NakCnt field adjustment rules.

<table>
<thead>
<tr>
<th>Token</th>
<th>Handshake</th>
<th>Handshake Nak</th>
<th>NYET</th>
</tr>
</thead>
<tbody>
<tr>
<td>IN/PING</td>
<td>decrement NakCnt</td>
<td>N/A (protocol error)</td>
<td></td>
</tr>
<tr>
<td>OUT</td>
<td>decrement NakCnt</td>
<td>No Action¹ Start</td>
<td></td>
</tr>
<tr>
<td>Split</td>
<td>decrement NakCnt</td>
<td>N/A (protocol error)</td>
<td></td>
</tr>
<tr>
<td>Complete Split</td>
<td>No Action</td>
<td>Decrement NakCnt</td>
<td></td>
</tr>
</tbody>
</table>

¹ Recommended behavior on this response is to reload NakCnt.
In summary, system software enables the counter by setting the reload field (RL) to a non-zero value. The host controller may execute a transaction if \textit{NakCnt} is non-zero. The host controller does not execute a transaction if \textit{NakCnt} is zero. The reload mechanism is described in detail in \textit{Nak Count Reload Control}.

\textbf{NOTE}
When all queue heads in the Asynchronous Schedule either exhausts all transfers or all NakCnt's go to zero, then the host controller detects an empty Asynchronous Schedule and idle schedule traversal (see \textit{Empty Asynchronous Schedule Detection}).

Any time the host controller begins a new traversal of the Asynchronous Schedule, a \textit{Start Event} is assumed, see \textit{Asynchronous schedule traversal: Start Event}. Every time a Start-Event occurs, the Nak Count reload procedure is enabled.

\section*{42.5.3.9.1 Nak Count Reload Control}

When the host controller reaches the \textit{Execute Transaction} state for a queue head (meaning that it has an active operational state), it checks to determine whether the \textit{NakCnt} field should be reloaded from \textit{RL} (see \textit{Execute Transaction}). If the answer is yes, then \textit{RL} is copied into \textit{NakCnt}. After the reload or if the reload is not active, the host controller evaluates whether to execute the transaction.

The host controller must reload nak counters (\textit{NakCnt} see \textit{Table 42-26}) in queue heads during the first pass through the reclamation list after an asynchronous schedule Start Event (see \textit{Asynchronous schedule traversal: Start Event} for the definition of the Start Event). The Asynchronous Schedule should have at most one queue head marked as the head (see \textit{Figure 42-14}).

The following figure illustrates an example state machine that satisfies the operational requirements of the host controller detecting the first pass through the Asynchronous Schedule. This state machine is maintained internal to the host controller and is only used to gate reloading of the nak counter during the queue head traversal state: Execute Transaction (see the figure below). The host controller does not perform the nak counter reload operation if the RL field (see \textit{Table 42-26}) is set to zero.
42.5.3.9.1.1 Wait for List Head

This is the initial state.

The state machine enters this state from Wait for Start Event when a start event as defined in Asynchronous schedule traversal: **Start Event** occurs.

The purpose of this state is to wait for the first observation of the head of the Asynchronous Schedule.

This occurs when the host controller fetches a queue head whose **H-bit** is set to one.

42.5.3.9.1.2 Do Reload

This state is entered from the Wait for List Head state when the host controller fetches a queue head with the **H-bit** set to one. While in this state, the host controller performs nak counter reloads for every queue head visited that has a non-zero nak reload value (**RL**) field.
42.5.3.9.1.3 Wait for Start Event

This state is entered from the Do Reload state when a queue head with the H-bit set to one is fetched. While in this state, the host controller does not perform nak counter reloads.

42.5.3.10 Managing Control/Bulk/Interrupt Transfers through Queue Heads

This section presents an overview of how the host controller interacts with queuing data structures.

Queue heads use the Queue Element Transfer Descriptor (qTD) structure. One queue head is used to manage the data stream for one endpoint. The queue head structure contains static endpoint characteristics and capabilities. It also contains a working area from where individual bus transactions for an endpoint are executed (see Overlay area defined in Table 42-26). Each qTD represents one or more bus transactions, which is defined in the context of this specification as a transfer.

The general processing model for the host controller's use of a queue head is simple:

- read a queue head,
- execute a transaction from the overlay area,
- write back the results of the transaction to the overlay area,
- move to the next queue head.

If the host controller encounters errors during a transaction, the host controller sets one (or more) of the error reporting bits in the queue head's Status field. The Status field accumulates all errors encountered during the execution of a qTD (for example, the error bits in the queue head Status field are 'sticky' until the transfer (qTD) has completed). This state is always written back to the source qTD when the transfer is complete. On transfer (for example, buffer or halt conditions) boundaries, the host controller must auto-advance (without software intervention) to the next qTD. Additionally, the hardware must be able to halt the queue so no additional bus transactions occurs for the endpoint and the host controller does not advance the queue.

An example host controller operational state machine of a queue head traversal is illustrated in the following figure. This state machine is a model for how a host controller should traverse a queue head. The host controller must be able to advance the queue from the Fetch QH state in order to avoid all hardware/software race conditions. This simple mechanism allows software to simply link qTDs to the queue head and activate them, then the host controller always find them if/when they are reachable. The figure below illustrates the Host Controller Queue Head Traversal State Machine.
This traversal state machine applies to all queue heads, regardless of transfer type or whether split transactions are required. The following sections describe each state. Each state description describes the entry criteria. The Execute Transaction state (see Execute
Transaction) describes the basic requirements for all endpoints. Split Transactions for Asynchronous Transfers and Split Transaction Interrupt describe details of the required extensions to the Execute Transaction state for endpoints requiring split transactions.

**NOTE**

Prior to software placing a queue head into either the periodic or asynchronous list, software must ensure the queue head is properly initialized. Minimally, the queue head should be initialized to the following (see Section Queue Head for layout of a queue head):

Valid static endpoint state.

- For the very first use of a queue head, software may zero-out the queue head transfer overlay, then set the Next qTD Pointer field value to reference a valid qTD.

### 42.5.3.10.1 Fetch Queue Head

A queue head can be referenced from the physical address stored in the ASYNCLISTADDR Register (see Next Asynch. Address (USB_nASYNCLISTADDR)/Endpoint List Address (USB_nENDPTLISTADDR) Additionally, it may be referenced from the Next LinkPointer field of an iTD, siTD, FSTN or another Queue Head. If the referencing link pointer has the Typ field set to indicate a queue head, it is assumed to reference a queue head structure as defined in Table 42-26.

While in this state, the host controller performs operations to implement empty schedule detection (see Empty Asynchronous Schedule Detection) and Nak Counter reloads (see Operational Model for Nak Counter). After the queue head has been fetched, the host controller conducts the following queries for empty schedule detection:

- If queue head is not an interrupt queue head (that is S-mask is zero), and
- The H-bit is one, and
- The Reclamation bit in the USBSTS register is zero.

When these criteria are met, the host controller stops traversing the asynchronous list (as described in Empty Asynchronous Schedule Detection). When the criteria are not met, the host controller continues schedule traversal. If the queue head is not an interrupt and the H-bit is one and the Reclamation bit is one, then the host controller sets the Reclamation bit in the USBSTS register to zero before completing this state. The operations for reloading of the Nak Counter are described in detail in Operational Model for Nak Counter.

This state is complete when the queue head has been read on-chip.
42.5.3.10.2  Advance Queue

To advance the queue, the host controller must find the next qTD, adjust pointers, perform the overlay and write back the results to the queue head.

This state is entered from the FetchQHD state if the overlay Active and Halt bits are set to zero. On entry to this state, the host controller determines which next pointer to use to fetch a qTD, fetches a qTD and determines whether or not to perform an overlay.

**NOTE**
If the I-bit is one and the Active bit is zero, the host controller immediately skips processing of this queue head, exits this state and uses the horizontal pointer to the next schedule data structure. If the field Bytes to Transfer is not zero and the T-bit in the Alternate Next qTD Pointer is set to zero, then the host controller uses the Alternate Next qTD Pointer. Otherwise, the host controller uses the NextqTD Pointer. If NextqTD Pointer's T-bit is set to one, then the host controller exits this state and uses the horizontal pointer to the next schedule data structure.

Using the selected pointer the host controller fetches the referenced qTD. If the fetched qTD has its Active bit set to one, the host controller moves the pointer value used to reach the qTD (Next or Alternate Next) to the Current qTD Pointer field, then performs the overlay. If the fetched qTD has its Active bit set to zero, the host controller aborts the queue advance and follows the queue head's horizontal pointer to the next schedule data structure.

The host controller performs the overlay based on the following rules:

- The value of the data toggle (dt) field in the overlay area depends on the value of the data toggle control (dtc) bit (see Table 42-28).
- If the EPS field indicates the endpoint is a high-speed endpoint, the Ping state field is preserved by the host controller. The value of this field is not changed as a result of the overlay.
- C-prog-mask field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- Frame Tag field is set to zero (field from incoming qTD is ignored, as is the current contents of the overlay area).
- NakCnt field in the overlay area is loaded from the RL field in the queue head's Static Endpoint State.
- All other areas of the overlay are set by the incoming qTD.

The host controller exits this state when it has committed the write to the queue head.
42.5.3.10.3 Execute Transaction

The host controller enters this state from the Fetch Queue Head state only if the Active bit in Status field of the queue head is set to one.

On entry to this state, the host controller executes a few pre-operations, then checks some pre-condition criteria before committing to executing a transaction for the queue head.

The pre-operations performed and the pre-condition criteria depend on whether the queue head is an interrupt endpoint. The host controller can determine that a queue head is an interrupt queue head when the queue head's S-mask field contains a non-zero value. It is the responsibility of software to ensure the S-mask field is appropriately initialized based on the transfer type. There are other criteria that must be met if the EPS field indicates that the endpoint is a low- or full-speed endpoint, see Split Transactions for Asynchronous Transfers and Split Transaction Interrupt.

42.5.3.10.3.1 Interrupt Transfer Pre-condition Criteria

If the queue head is for an interrupt endpoint (for example, non-zero S-mask field), then the FRINDEX[2:0] field must identify a bit in the S-mask field that has one in it.

For example, an S-mask value of 00100000b would evaluate to true only when FRINDEX[2:0] is equal to 101b. If this condition is met then the host controller considers this queue head for a transaction.

42.5.3.10.3.2 Asynchronous Transfer Pre-operations and Pre-condition Criteria

If the queue head is not for an interrupt endpoint (for example, zero S-mask field), then the host controller performs one pre-operation and then evaluates one pre-condition criteria.

The pre-operation is:

Checks the Nak counter reload state (Operational Model for Nak Counter). It may be necessary for the host controller to reload the Nak Counter field. The reload is performed at this time.

The pre-condition evaluated is:

- Whether or not the NakCnt field has been reloaded, the host controller checks the value of the NakCnt field in the queue head. If NakCnt is non-zero, or if the Reload Nak Counter field is zero, then the host controller considers this queue head for a transaction.
42.5.3.10.3.3 Transfer Type Independent Pre-operations

Regardless of the transfer type, the host controller always performs at least one pre-operation and evaluates one pre-condition. The pre-operation is:

- A host controller internal transaction (down) counter \(qHTransactionCounter\) is loaded from the queue head's \(Mult\) field. A host controller implementation is allowed to ignore this for queue heads on the asynchronous list. It is mandatory for interrupt queue heads. Software should ensure that the \(Mult\) field is set appropriately for the transfer type.

The pre-conditions evaluated are:

- The host controller determines whether there is enough time in the micro-frame to complete this transaction (see Transaction Fit - A Best-Fit Approximation Algorithm for an example evaluation method). If there is not enough time to complete the transaction, the host controller exits this state.
- If the value of \(qHTransactionCounter\) for an interrupt endpoint is zero, then the host controller exits this state.

When the pre-operations are complete and pre-conditions are met, the host controller sets the Reclamation bit in the USBSTS register to one and then begins executing one or more transactions using the endpoint information in the queue head. The host controller iterates \(qHTransactionCounter\) times in this state executing transactions. After each transaction is executed, \(qHTransactionCounter\) is decremented by one. The host controller exits this state when one of the following events occurs:

- The \(qHTransactionCounter\) decrements to zero, or
- The endpoint responds to the transaction with any handshake other than an ACK,\(^4\) or
- The transaction experiences a transaction error, or
- The \(Active\) bit in the queue head goes to zero, or
- There is not enough time in the micro-frame left to execute the next transaction (see Transaction Fit - A Best-Fit Approximation Algorithm for example method for implementing the frame boundary test).

**NOTE**

For a high-bandwidth interrupt OUT endpoint, the host controller may optionally immediately retry the transaction if it fails.

The results of each transaction is recorded in the on-chip overlay area. If data was successfully moved during the transaction, the transfer state in the overlay area is advanced. To advance queue head's transfer state, the Total Bytes to Transfer field is decremented by the number of bytes moved in the transaction, the data toggle bit \((dt)\) is toggled, the current page offset is advanced to the next appropriate value (for example,
advanced by the number of bytes successfully moved), and the $C_{Page}$ field is updated to the appropriate value (if necessary). See Buffer Pointer List Use for Data Streaming with qTDs.

**NOTE**

The *Total Bytes To Transfer* field may be zero when all the other criteria for executing a transaction are met. When this occurs, the host controller executes zero-length transaction to the endpoint. If the $PID_{Code}$ field indicates an IN transaction and the device delivers data, the host controller detects a packet babble condition, set the *babble* and *halted* bits in the *Status* field, set the *Active* bit to zero, write back the results to the source qTD, then exit this state.

In the event an IN token receives a data PID mismatch response, the host controller must ignore the received data (for example not advance the transfer state for the bytes received). Additionally, if the endpoint is an interrupt IN, then the host controller must record that the transaction occurred (for example, decrement $qHTransactionCounter$). It is recommended (but not required) the host controller continue executing transactions for this endpoint if the resultant value of $qHTransactionCounter$ is greater than one.

If the response to the IN bus transaction is a Nak (or Nyet) and $RL$ is non-zero, $NakCnt$ is decremented by one. If $RL$ is zero, then no write-back by the host controller is required (for a transaction receiving a Nak or Nyet response and the value of $CErr$ did not change). Software should set the $RL$ field to zero if the queue head is an interrupt endpoint. Host controller hardware is not required to enforce this rule or operation.

After the transaction has finished and the host controller has completed the post processing of the results (advancing the transfer state and possibly $NakCnt$, the host controller writes back the results of the transaction to the queue head's overlay area in main memory).

The number of bytes moved during an IN transaction depends on how much data the device endpoint delivers. The maximum number of bytes a device can send is *MaximumPacket Size*. The number of bytes moved during an OUT transaction is either *Maximum Packet Length* bytes or *Total Bytes to Transfer*, whichever is less.

If there was a transaction error during the transaction, the transfer state (as defined above) is not advanced by the host controller. The $CErr$ field is decremented by one and the status field is updated to reflect the type of error observed. Transaction errors are summarized in **Transaction Error**.
The following events causes the host controller to clear the *Active* bit in the queue head's overlay status field. When the *Active* bit transitions from one to zero, the transfer in the overlay is considered complete. The reason for the transfer completion (clearing the *Active* bit) determines the next state.

- *CErr* field decrements to zero. When this occurs the *Halted* bit is set to one and *Active* is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The device responds to the transaction with a STALL PID. When this occurs, the *Halted* bit is set to one and the *Active* bit is set to zero. This results in the hardware not advancing the queue and the pipe halts. Software must intercede to recover.
- The *Total Bytes to Transfer* field is zero after the transaction completes.
  - For a zero length transaction, it was zero before the transaction was started. When this condition occurs, the *Active* bit is set to zero.
- The PID code is an IN, and the number of bytes moved during the transaction is less than the *Maximum Packet Length*. When this occurs, the *Active* bit is set to zero and a short packet condition exists. The short-packet condition is detected during the Advance Queue state. Refer to Split Transactions for additional rules for managing low- and full-speed transactions.

With the exception of a NAK response (when *RL* field is zero), the host controller always writes the results of the transaction back to the overlay area in main memory. This includes when the transfer completes. For a high-speed endpoint, the queue head information written back includes minimally the following fields: The *PID Code* field indicates an IN and the device sends more than the expected number of bytes (for example *Maximum Packet Length* or *Total Bytes to Transfer* bytes, whichever is less) (for example a packet babble). This results in the host controller setting the *Halted* bit to one.

- NakCnt, dt, Total Bytes to Transfer, C_Page, Status, CERR, and Current Offset

For a low- or full-speed device the queue head information written back also includes the fields:

- C-prog-mask, FrameTag and S-bytes.

The duration of this state depends on the time it takes to complete the transaction(s) and the status write to the overlay is committed.

### 42.5.3.10.3.4 Halting a Queue Head

A halted endpoint is defined only for the transfer types that are managed through queue heads (control, bulk and interrupt).

The following events indicate that the endpoint has reached a condition where no more activity can occur without intervention from the driver:
• An endpoint may return a STALL handshake during a transaction,
• A transaction had three consecutive error conditions, or
• A Packet Babble error occurs on the endpoint.

When any of these events occur (for a queue head) the Host Controller halts the queue head and set the USBERRINT status bit in the USB_n_USBSTS register to one. To halt the queue head, the Active bit is set to zero and the Halted bit is set to one. There may be other error status bits that are set when a queue is halted. The host controller always writes back the overlay area to the source qTD when the transfer is complete, regardless of the reason (normal completion, short packet or halt). The host controller does not advance the transfer state on a transaction that results in a Halt condition (for example no updates necessary for Total Bytes to Transfer, C_Page, Current Offset, and dt). The host controller must update CErr as appropriate. When a queue head is halted, the USB Error Interrupt bit in the USB_n_USBSTS register is set to one. If the USB Error Interrupt Enable bit in the USB_n_USBINTR register is set to one, a hardware interrupt is generated at the next interrupt threshold.

42.5.3.10.3.5  Asynchronous Schedule Park Mode

Asynchronous Schedule Park mode is a special execution mode that can be enabled by system software, where the host controller is permitted to execute more than one bus transaction from a high-speed queue head in the Asynchronous schedule before continuing horizontal traversal of the Asynchronous schedule.

This feature has no effect on queue heads or other data structures in the Periodic schedule. This feature is similar in intent as the Mult feature that is used in the Periodic schedule. Where-as the Mult feature is a characteristic that is tunable for each endpoint; park-mode is a policy that is applied to all high-speed queue heads in the asynchronous schedule. It is essentially the specification of an iterator for consecutive bus transactions to the same endpoint. All of the rules for managing bus transactions and the results of those as defined in Execute Transaction apply. This feature merely specifies how many consecutive times the host controller is permitted to execute from the same queue head before moving to the next queue head in the Asynchronous List. This feature should allow the host controller to attain better bus utilization for those devices that are capable of moving data at maximum rate, while at the same time providing a fair service to all endpoints.

A host controller exports its capability to support this feature to system software by setting the Asynchronous Schedule Park Capability bit in the USB_n_HCCPARAMs register to one. This information keys system software that the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USB_n_USBCMD register are modifiable. System software enables the feature by writing a one to the Asynchronous Schedule Park Mode Enable bit.
When park-mode is not enabled (for example Asynchronous Schedule Park Mode Enable bit in the USB_n_USB_CMD register is zero), the host controller must not execute more than one bus transaction per high-speed queue head, per traversal of the asynchronous schedule. When park-mode is enabled, the host controller must not apply the feature to a queue head whose EPS field indicates a Low/Full-speed device (for example only one bus transaction is allowed from each Low/Full-speed queue head per traversal of the asynchronous schedule). Park-mode may only be applied to queue heads in the Asynchronous schedule whose EPS field indicates that it is a high-speed device.

The host controller must apply park mode to queue heads whose EPS field indicates a high-speed endpoint. The maximum number of consecutive bus transactions a host controller may execute on a high-speed queue head is determined by the value in the Asynchronous Schedule Park Mode Count field in the USB_n_USB_CMD register. Software must not set Asynchronous Schedule Park Mode Enable bit to one and also set Asynchronous Schedule Park Mode Count field to zero. The resulting behavior is not defined. An example behavioral example describes the operational requirements for the host controller implementing park-mode. This feature does not affect how the host controller handles the bus transaction as defined in Execute Transaction. It only affects how many consecutive bus transactions for the current queue head can be executed. All boundary conditions, error detection and reporting applies as usual. This feature is similar in concept to the use of the Mult field for high-bandwidth Interrupt for queue heads in the Periodic Schedule.

The host controller effectively loads an internal down-counter PM-Count from Asynchronous Schedule Park Mode Count when Asynchronous Schedule Park Mode Enable bit is one, and a high-speed queue head is first fetched and meets all the criteria for executing a bus transaction. After the bus transaction, PM-Count is decremented. The host controller may continue to execute bus transactions from the current queue head until PM-Count goes to zero, an error is detected, the buffer for the current transfer is exhausted or the endpoint responds with a flow-control or STALL handshake.

The following table summarizes the responses that effect whether the host controller continues with another bus transaction for the current queue head.

1. The host controller may continue to execute bus transactions from the current high-speed queue head (if PM-Count is not equal to zero), if a PID mismatch is detected (for example expected DATA1 and received DATA0, or visa-versa).
2. This specification does not require that the host controller execute another bus transaction when PM-Count is non-zero. Implementations are encouraged to make appropriate complexity and performance trade-offs.

42.5.3.10.4 Write Back qTD

This state is entered from the Execute Transaction state when the Active bit is set to zero. The source data for the write-back is the transfer results area of the queue head overlay area (see Table 42-44).

The host controller uses the Current qTD Pointer field as the target address for the qTD. The queue head transfer result area is written back to the transfer result area of the target qTD. This state is also referred to as: qTD retirement. The fields that must be written back to the source qTD include Total Bytes to Transfer, Cerr, and Status.

The duration of this state depends on when the qTD write-back is committed.

42.5.3.10.5 Follow Queue Head Horizontal Pointer

The host controller must use the horizontal pointer in the queue head to the next schedule data structure when any of the following conditions exist:

- If the Active bit is one on exit from the Execute Transaction state, or
- When the host controller exits the Write Back qTD state, or
- If the Advance Queue state fails to advance the queue because the target qTD is not active, or
- If the Halted bit is one on exit from the Fetch QH state.
There is no functional requirement that the host controller wait until the current 
transaction is complete before using the horizontal pointer to read the next linked data 
structure. However, it must wait until the current transaction is complete before executing 
the next data structure.

42.5.3.10.6 Buffer Pointer List Use for Data Streaming with qTDs

A qTD has an array of buffer pointers, which is used to reference the data buffer for a 
transfer. This specification requires that the buffer associated with the transfer be 
virtually contiguous.

This means: if the buffer spans more than one physical page, it must obey the following 
rules (the figure below illustrates an example):

- The first portion of the buffer must begin at some offset in a page and extend through 
  the end of the page.
- The remaining buffer cannot be allocated in small chunks scattered around memory. 
  For each 4 K chunk beyond the first page, each buffer portion matches to a full 4 K 
  page. The final portion, which may only be large enough to occupy a portion of a 
  page, must start at the top of the page and be contiguous within that page.

The buffer pointer list in the qTD is long enough to support a maximum transfer size of 
20 K bytes. This case occurs when all five buffer pointers are used and the first offset is 
zero. A qTD handles a 16 Kbyte buffer with any starting buffer alignment.

The host controller uses the field C_Page field as an index value to determine which 
buffer pointer in the list should be used to start the current transaction. The host controller 
uses a different buffer pointer for each physical page of the buffer. This is always true, 
even if the buffer is physically contiguous.

The host controller must detect when the current transaction spans a page boundary and 
automatically move to the next available buffer pointer in the page pointer list. The next 
available pointer is reached by incrementing C_Page and pulling the next page pointer 
from the list. Software must ensure there are sufficient buffer pointers to move the 
amount of data specified in the Bytes to Transfer field.

The following figure illustrates a nominal example of how System software would 
initialize the buffer pointers list and the C_Page field for a transfer size of 16383 bytes. 
C_Page is set to zero. The upper 20-bits of Page 0 references the start of the physical 
page. Current Offset (the lower 12-bits of queue head Dword 7) holds the offset in the 
page for example 2049 (for example 4096-2047). The remaining page pointers are set to 
reference the beginning of each subsequent 4 K page.
For the first transaction on the qTD (assuming a 512-byte transaction), the host controller uses the first buffer pointer (page 0 because $C\_Page$ is set to zero) and concatenates the Current Offset field. The 512 bytes are moved during the transaction, the Current Offset and Total Bytes to Transfer are adjusted by 512 and written back to the queue head working area.

During the 4th transaction, the host controller needs 511 bytes in page 0 and one byte in page 1. The host controller increments $C\_Page$ (to 1) and use the page 1 pointer to move the final byte of the transaction. After the 4th transaction, the active page pointer is the page 1 pointer and Current Offset has rolled to one, and both are written back to the overlay area. The transactions continue for the rest of the buffer, with the host controller automatically moving to the next page pointer (that is $C\_Page$) when necessary. The three conditions for how the host controller handles $C\_Page$:

- The current transaction does not span a page boundary. The value of $C\_Page$ is not adjusted by the host controller.
• The current transaction does span a page boundary. The host controller must detect the page cross condition and advance to the next buffer while streaming data to/from the USB.
• The current transaction completes on a page boundary (that is the last byte moved for the current transaction is the last byte in the page for the current page pointer). The host controller must increment $C_{Page}$ before writing back status for the transaction.

**NOTE**

The only valid adjustment the host controller may make to $C_{Page}$ is to increment by one.

### 42.5.3.10.7 Adding Interrupt Queue Heads to the Periodic Schedule

The link path(s) from the periodic frame list to a queue head establishes in which frames a transaction can be executed for the queue head. Queue heads are linked into the periodic schedule so they are polled at the appropriate rate.

System software sets a bit in a queue head's $S$-Mask to indicate which micro-frame within 1 msec period a transaction should be executed for the queue head. Software must ensure that all queue heads in the periodic schedule have $S$-Mask set to a non-zero value. An $S$-mask with zero value in the context of the periodic schedule yields undefined results.

If the desired poll rate is greater than one frame, system software can use a combination of queue head linking and $S$-Mask values to spread interrupts of equal poll rates through the schedule so that the periodic bandwidth is allocated and managed in the most efficient manner possible. Some examples are illustrated in the following table.

<table>
<thead>
<tr>
<th>Frame # Reference Sequence</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0, 2, 4, 6, 8, and so on S-Mask = 01h</td>
<td>A queue head for the bInterval of 2 msec (16 micro-frames) is linked into the periodic schedule so that it is reachable from the periodic frame list locations indicated in the previous column. In addition, the S-Mask field in the queue head is set to 01h, indicating that the transaction for the endpoint should be executed on the bus during micro-frame 0 of the frame.</td>
</tr>
<tr>
<td>0, 2, 4, 6, 8, and so on S-Mask = 02h</td>
<td>Another example of a queue head with a bInterval of 2 msec is linked into the periodic frame list at exactly the same interval as the previous example. However, the S-Mask is set to 02h indicating that the transaction for the endpoint should be executed on the bus during micro-frame 1 of the frame.</td>
</tr>
</tbody>
</table>
Managing Transfer Complete Interrupts from Queue Heads

The host controller sets an interrupt to be signaled at the next interrupt threshold when the completed transfer (qTD) has an Interrupt on Complete (IOC) bit set to one, or whenever a transfer (qTD) completes with a short packet.

If system software needs multiple qTDs to complete a client request (that is like a control transfer) the intermediate qTDs do not require interrupts. System software may only need a single interrupt to notify it that the complete buffer has been transferred. System software may set IOC's to occur more frequently. A motivation for this may be that it wants early notification so that interface data structures can be re-used in a timely manner.

Ping Control

USB 2.0 defines an addition to the protocol for high-speed devices called Ping. Ping is required for all USB 2.0 High-speed bulk and control endpoints.

Ping is not allowed for a split-transaction stream. This extension to the protocol eliminates the bad side-effects of Naking OUT endpoints. The Status field has a Ping State bit, which the host controller uses to determine the next actual PID it uses in the next transaction to the endpoint (see the table below).

The Ping State bit is only managed by the host controller for queue heads that meet the following criteria:

- Queue head is not an interrupt and
- EPS field equals High-Speed and
- PIDCode field equals OUT

The following table illustrates the state transition table for the host controller's responsibility for maintaining the PING protocol. Refer to Chapter 8 in the USB Specification Revision 2.0 for detailed description on the Ping protocol.

<table>
<thead>
<tr>
<th>Event</th>
<th>Current</th>
<th>Host</th>
<th>Device</th>
<th>Next</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>Do OUT</td>
<td>OUT</td>
<td>XactErr(^1)</td>
<td>Do Ping</td>
</tr>
<tr>
<td>Do OUT</td>
<td>OUT</td>
<td>Stall</td>
<td>N/C(^2)</td>
</tr>
</tbody>
</table>

1. Transaction Error (XactErr) is any time the host misses the handshake.
2. No transition change required for the Ping State bit. The Stall handshake results in the endpoint being halted (for example Active set to zero and Halt set to one). Software intervention is required to restart queue. 3 A Nyet response to an OUT means that the device has accepted the data, but cannot receive any more at this time. Host must advance the transfer state and additionally, transition the Ping State bit to Do Ping. The Ping State bit has the following encoding:

Table 42-47. Ping State bit Encoding

<table>
<thead>
<tr>
<th>Value</th>
<th>Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>0B</td>
<td>Do OUT  The host controller uses an OUT PID during the next bus transaction to this endpoint.</td>
</tr>
<tr>
<td>1B</td>
<td>Do Ping The host controller uses a PING PID during the next bus transaction to this endpoint.</td>
</tr>
</tbody>
</table>

The defined ping protocol (see USB 2.0 Specification, Chapter 8) allows the host to be *imprecise* on the initialization of the ping protocol (that is start in *Do OUT* when we don’t know whether there is space on the device or not). The host controller manages the *Ping State* bit. System software sets the initial value in the queue head when it initializes a queue head. The host controller preserves the *Ping State* bit across all queue advancements. This means that when a new qTD is written into the queue head overlay area, the previous value of the *Ping State* bit is preserved.

**42.5.3.12 Split Transactions**

USB 2.0 defines extensions to the bus protocol for managing USB 1.x data streams through USB 2.0 Hubs.

This section describes how the host controller uses the interface data structures to manage data streams with full- and low-speed devices, connected below USB 2.0 hub, utilizing the split transaction protocol.

Refer to USB 2.0 Specification for the complete definition of the split transaction protocol. Full- and Low-speed devices are enumerated identically as high-speed devices, but the transactions to the Full- and Low-speed endpoints use the split-transaction protocol on the high-speed bus. The split transaction protocol is an encapsulation of (or wrapper around) the Full- or Low-speed transaction. The high-speed wrapper portion of the protocol is addressed to the USB 2.0 Hub and Transaction Translator below which the Full- or Low-speed device is attached.
The EHCI interface uses dedicated data structures for managing full-speed isochronous data streams (see Split Transaction Isochronous Transfer Descriptor (siTD)). Control, Bulk and Interrupt are managed using the queuing data structures (see Queue Head). The interface data structures need to be programmed with the device address and the Transaction Translator number of the USB 2.0 Hub operating as the Low-/Full-speed host controller for this link. The following sections describe the details of how the host controller must process and manage the split transaction protocol.

42.5.3.12.1 Split Transactions for Asynchronous Transfers

A queue head in the asynchronous schedule with an $EPS$ field indicating a full-or low-speed device indicates to the host controller that it must use split transactions to stream data for this queue head.

All full-speed bulk and full-, low-speed control are managed through queue heads in the asynchronous schedule.

Software must initialize the queue head with the appropriate device address and port number for the transaction translator that is serving as the full/low-speed host controller for the links connecting the endpoint. Software must also initialize the split transaction state bit ($SplitXState$) to Do-Start-Split. Finally, if the endpoint is a control endpoint, then system software must set the Control Transfer Type ($C$) bit in the queue head to one. If this is not a control transfer type endpoint, the $C$ bit must be initialized by software to be zero. This information is used by the host controller to properly set the Endpoint Type (ET) field in the split transaction bus token. When the $C$ bit is zero, the split transaction token's ET field is set to indicate a bulk endpoint. When the $C$ bit is one, the split transaction token's ET field is set to indicate a control endpoint. Refer to Chapter 8 of USB Specification Revision 2.0 for details.

![Figure 42-19. Host Controller Asynchronous Schedule Split-Transaction State Machine](image-url)
42.5.3.12.1.1  Asynchronous - Do Start Split

This is the state which software must initialize a full- or low-speed asynchronous queue head. This state is entered from the Do Complete Split state only after a complete-split transaction receives a valid response from the transaction translator that is not a Nyet handshake.

For queue heads in this state, the host controller executes a start-split transaction to the appropriate transaction translator. If the bus transaction completes without an error and PidCode indicates an IN or OUT transaction, then the host controller reloads the error counter (CErr). If it is a successful bus transaction and the PidCode indicates a SETUP, the host controller does not reload the error counter. If the transaction translator responds with a Nak, the queue head is left in this state, and the host controller proceeds to the next queue head in the asynchronous schedule.

If the host controller times out the transaction (no response, or bad response) the host controller decrements Cerr and proceeds to the next queue head in the asynchronous schedule.

42.5.3.12.1.2  Asynchronous - Do Complete Split

This state is entered from the Do Start Split state only after a start-split transaction receives an Ack handshake from the transaction translator.

For queue heads in this state, the host controller executes a complete-split transaction to the appropriate transaction translator. If the transaction translator responds with a Nyet handshake, the queue head is left in this state, the error counter is reset and the host controller proceeds to the next queue head in the asynchronous schedule. When a Nyet handshake is received for a bus transaction where the queue head's PidCode indicates an IN or OUT, the host controller reloads the error counter (CErr). When a Nyet handshake is received for a complete-split bus transaction where the queue head's PidCode indicates a SETUP, the host controller must not adjust the value of CErr.

Independent of PidCode, the following responses have the effects:

- Transaction Error (XactErr). Timeout or data CRC failure, and so on. The error counter (Cerr) is decremented by one and the complete split transaction is immediately retried (if possible). If there is not enough time in the micro-frame to execute the retry, the host controller MUST ensure that the next time the host controller begins executing from the Asynchronous schedule, it must begin executing from this queue head. If another start-split (for some other endpoint) is sent to the transaction translator before the complete-split is really completed, the transaction translator could dump the results (which were never delivered to the host). This is why the core specification states the retries must be immediate. A method to
accomplish this behavior is to not advance the asynchronous schedule. When the host controller returns to the asynchronous schedule in the next micro-frame, the first transaction from the schedule is the retry for this endpoint.

If $Cerr$ went to zero, the host controller must halt the queue.

- **NAK.** The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced and the state is exited. If the $PidCode$ is a SETUP, then the Nak response is a protocol error. The $XactErr$ status bit is set to one and the $CErr$ field is decremented.

- **STALL.** The target endpoint responded with a STALL handshake. The host controller sets the $halt$ bit in the status byte, retires the qTD but does not attempt to advance the queue.

If the $PidCode$ indicates an IN, then any of following responses are expected:

- **DATA0/1.** On reception of data, the host controller ensures the PID matches the expected data toggle and checks CRC. If the packet is $good$, the host controller advances the state of the transfer, for example move the data pointer by the number of bytes received, decrement $BytesToTransfer$ field by the number of bytes received, and toggle the $dt$ bit. The host controller then exit this state. The response and advancement of transfer may trigger other processing events, such as retirement of the qTD and advancement of the queue.

If the data sequence PID does not match the expected, the data is ignored, the transfer state is not advanced and this state is exited. If the $PidCode$ indicates an OUT/SETUP, then any of following responses are expected:

- **ACK.** The target endpoint accepted the data, so the host controller must advance the state of the transfer. The $Current Offset$ field is incremented by $Maximum Packet Length$ or $Bytes to Transfer$, whichever is less. The field $Bytes To Transfer$ is decremented by the same amount and the data toggle bit ($dt$) is toggled. The host controller then exit this state.

- Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Managing Control/Bulk/Interrupt Transfers through Queue Heads).

### 42.5.3.12.2 Split Transaction Interrupt

Split-transaction Interrupt-IN/OUT endpoints are managed through the same data structures used for high-speed interrupt endpoints. They both co-exist in the periodic schedule.
Queue heads/qTDs offer the set of features required for reliable data delivery, which is characteristic to interrupt transfer types. The split-transaction protocol is managed completely within this defined functional transfer framework. For example, for a high-speed endpoint, the host controller visits a queue head, execute a high-speed transaction (if criteria are met) and advance the transfer state (or not) depending on the results of the entire transaction. For low- and full-speed endpoints, the details of the execution phase are different (that is takes more than one bus transaction to complete), but the remainder of the operational framework is intact. This means that the transfer advancement, and so on, occurs as defined in Managing Control/Bulk/Interrupt Transfers through Queue Heads, but only occurs on the completion of a split transaction.

42.5.3.12.2.1 Split Transaction Scheduling Mechanisms for Interrupt

Full- and low-speed Interrupt queue heads have an EPS field indicating full- or low-speed and have a non-zero S-mask field.

The host controller can detect this combination of parameters and assume the endpoint is a periodic endpoint. Low- and full-speed interrupt queue heads require the use of the split transaction protocol. The host controller sets the Endpoint Type (ET) field in the split token to indicate the transaction is an interrupt. These transactions are managed through a transaction translator's periodic pipeline. Software should not set these fields to indicate the queue head is an interrupt unless the queue head is used in the periodic schedule.

System software manages the per/transaction translator periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each endpoint occurs. The characteristics of the transaction translator are such that the high-speed transaction protocol must execute during explicit micro-frames, or the data or response information in the pipeline is lost.

The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule and queue head data structure. The S and C\text{X} labels indicate micro-frames where software can schedule start-splits and complete splits (respectively).
The scheduling cases are:

- Case 1: The normal scheduling case is where the entire split transaction is completely bounded by a frame (*H-Frame* in this case).
- Case 2a through Case 2c: The USB 2.0 Hub pipeline rules states clearly, when and how many complete-splits must be scheduled to account for earliest to latest execution on the full/low-speed link. The complete-splits may span the *H-Frame* boundary when the start-split is in micro-frame 4 or later. When this occurs, the *H-Frame* to *B-Frame* alignment requires that the queue head be reachable from consecutive periodic frame list locations. System software cannot build an efficient schedule that satisfies this requirement unless it uses FSTNs.

The figure below illustrates the general layout of the periodic schedule.

**Figure 42-20. Split Transaction, Interrupt Scheduling Boundary Conditions**
The periodic frame list is effectively the leaf level a binary tree, which is always traversed leaf to root. Each level in the tree corresponds to a \( 2^N \) poll rate. Software can efficiently manage periodic bandwidth on the USB by *spreading* interrupt queue heads that have the same poll rate requirement across all the available paths from the frame list. For example, system software can schedule eight poll rate 8 queue heads and account for them once in the high-speed bus bandwidth allocation.

When an endpoint is allocated an execution footprint that spans a frame boundary, the queue head for the endpoint must be reachable from consecutive locations in the frame list. An example would be if \( 8_{0b} \), where such an endpoint. Without additional support on the interface, to get \( 8_{0b} \) reachable at the correct time, software would have to link \( 8_1 \) to \( 8_{0b} \). It would then have to move \( 4_1 \) and everything linked after into the same path as \( 4_0 \). This upsets the integrity of the binary tree and disallows the use of the spreading technique.

FSTN data structures are used to preserve the integrity of the binary-tree structure and enable the use of the spreading technique. Host Controller Operational Model for FSTNs defines the hardware and software operational model requirements for using FSTNs.
The following queue head fields are initialized by system software to instruct the host controller when to execute portions of the split-transaction protocol:

- **SplitXState.** This is single bit residing in the Status field of a queue head (see Table 42-24). This bit is used to track the current state of the split transaction.

- **Frame S-mask.** This is a bit-field where system software sets a bit corresponding to the micro-frame (within an H-Frame) that the host controller should execute a start-split transaction. This is always qualified by the value of the SplitXState bit in the Status field of the queue head. For example, referring to Figure 42-20, case one, the S-mask would have a value of 00000001b indicating that if the queue head is traversed by the host controller, and the SplitXState indicates Do_Start, and the current micro-frame as indicated by FRINDEX[2:0] is 0, then execute a start-split transaction.

- **Frame C-mask.** This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an H-Frame) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the SplitXState bit in the Status field of the queue head. For example, referring to Figure 42-20, case one, the C-mask would have a value of 00011100b indicating that if the queue head is traversed by the host controller, and the SplitXState indicates Do_Complete, and the current micro-frame as indicated by FRINDEX[2:0] is 2, 3, or 4, then execute a complete-split transaction. It is software's responsibility to ensure that the translation between H-Frames and B-Frames is correctly performed when setting bits in S-mask and C-mask.

### 42.5.3.12.2.2 Host Controller Operational Model for FSTNs

The FSTN data structure is used to manage Low/Full-speed interrupt queue heads that need to be reached from consecutive frame list locations (that is boundary cases 2a through 2c).

An FSTN is essentially a *back pointer*, similar in intent to the back pointer field in the siTD data structure (see siTD Back Link Pointer).

This feature provides software a simple primitive to save a schedule position, redirect the host controller to traverse the necessary queue heads in the previous frame, then restore the original schedule position and complete normal traversal.

The four components to the use of FSTNs:

- FSTN data structure.
- A *Save Place* indicator. This is always an FSTN with its Back Path Link Pointer.T-bit set to zero.
• A *Restore* indicator. This is always an FSTN with its *Back Path Link Pointer* T-bit set to one.
• Host controller FSTN traversal rules.

When the host controller encounters an FSTN during micro-frames 2 through 7 it simply follows the node's *Normal Path Link Pointer* to access the next schedule data structure.

**NOTE**

The FSTN's *Normal Path Link Pointer* T-bit may set to one, which the host controller must interpret as the end of periodic list mark.

When the host controller encounters a *Save-Place* FSTN in micro-frames 0 or 1, it saves the value of the *Normal Path Link Pointer* and set an internal flag indicating that it is executing in *Recovery Path* mode. *Recovery Path* mode modifies the host controller's rules for how it traverses the schedule and limits which data structures is considered for execution of bus transactions. The host controller continues executing in *Recovery Path* mode until it encounters a *Restore* FSTN or it determines that it has reached the end of the micro-frame (see details in the list below).

The rules for schedule traversal and limited execution while in *Recovery Path* mode are:

• Always follow the *Normal Path Link Pointer* when it encounters an FSTN that is a *Save-Place* indicator. The host controller must not recursively follow *Save-Place* FSTNs. Therefore, while executing in *Recovery Path* mode, it must never follow an FSTN's *Back Path Link Pointer*.
• Do not process an siTD or, iTD data structure. Simply follow its *Next Link Pointer*.
• Do not process a QH (Queue Head) whose *EPS* field indicates a high-speed device. Simply follow its *Horizontal Link Pointer*.
• When a QH's *EPS* field indicates a Full/Low-speed device, the host controller considers only it for execution if its *SplitXState* is DoComplete (note: this applies whether the *PID Code* indicates an IN or an OUT). See *Execute Transaction* and *Tracking Split Transaction Progress for Interrupt Transfers* for a complete list of additional conditions that must be met in general for the host controller to issue a bus transaction.
  • The host controller must not execute a Start-split transaction while executing in *Recovery Path* mode. See *Periodic Isochronous - Do Complete Split* for special handling when in *Recovery Path* mode.
• Stop traversing the *recovery path* when it encounters an FSTN that is a *Restore* indicator. The host controller unconditionally uses the saved value of the *Save-Place* FSTN's *Normal Path Link Pointer* when returning to the normal path traversal. The
host controller must clear the context of executing a Recovery Path when it restores schedule traversal to the Save-Place FSTN's Normal Path Link Pointer.

- If the host controller determines that there is not enough time left in the micro-frame to complete processing of the periodic schedule, it abandons traversal of the recovery path, and clears the context of executing a recovery path. The result is that at the start of the next consecutive micro-frame, the host controller starts traversal at the frame list.

An example traversal of a periodic schedule that includes FSTNs is illustrated in the following figure.

**Figure 42-22. Example Host Controller Traversal of Recovery Path via FSTNs**

In frame N+1 (micro-frames 0 and 1), when the host controller encounters Save-Path FSTN (Save-N), it observes that Save-N.Back Path Link Pointer.T-bit is zero (definition of a Save-Path indicator). The host controller saves the value of Save-N.Normal Path Link Pointer and follows Save-N.Back Path Link Pointer. At the same time, it sets an internal flag indicating that it is now in Recovery Path mode (the recovery path is annotated in the figure above with a large dashed line). The host controller continues traversing data structures on the recovery path and executing only those bus transactions as noted above, on the recovery path until it reaches Restore FSTN (Restore-N). Restore-N.Back Path Link Pointer.T-bit is set to one (definition of a Restore indicator), so the host controller exits Recovery Path mode by clearing the internal Recovery Path mode flag and commences (restores) schedule traversal using the saved value of the Save-Place FSTN's Normal Path Link Pointer (for example Save-N.Normal Path Link Pointer). The nodes traversed during these micro-frames include: \( \{8_{3,0}, 8_{3,1}, 8_{3,2}, \text{Save-A}, 8_{2,2}, 8_{2,3}, 4_{2}, \ldots \} \).
2_0, Restore-N, 4_3, 2_1, Restore-N, 1_0 \ldots \}. The nodes on the recovery-path are in bold. In frame N (micro-frames 0-7), for this example, the host controller traverses all of the schedule data structures utilizing the \textit{Normal Path Link Pointers} in any FSTNs it encounters. This is because the host controller has not yet encountered a \textit{Save-Place} FSTN so it not executing in \textit{Recovery Path} mode. When it encounters the \textit{Restore} FSTN, (Restore-N), during micro-frames 0 and 1, it uses Restore-N.Normal Path Link Pointer to traverse to the next data structure (that is normal schedule traversal). This is because the host controller must use a Restore FSTN's \textit{Normal Path Link Pointer} when not executing in a \textit{Recovery-Path} mode. The nodes traversed during frame N include: \{8_2.0, 8_2.1, 8_2.2, 8_2.3, 4_2, 2_0, Restore-N, 1_0 \ldots \}.

In frame N+1 (micro-frames 2-7), when the host controller encounters Save-Path FSTN Save-N, it unconditionally follows Save-N.Normal Path Link Pointer. The nodes traversed during these micro-frames include: \{8_3.0, 8_3.1, 8_3.2, Save-A, 4_3, 2_1, Restore-N, 1_0 \ldots \}.

### 42.5.3.12.2.3 Software Operational Model for FSTNs

Software must create a consistent, coherent schedule for the host controller to traverse.

When using FSTNs, system software must adhere to the following rules:

- Each \textit{Save-Place} indicator requires a matching \textit{Restore} indicator.
  - The \textit{Save-Place} indicator is an FSTN with a valid \textit{Back Path Link Pointer} and \textit{T-bit} equal to zero.
  - \textit{Back Path Link Pointer.Typ} field must be set to indicate the referenced data structure is a queue head. The \textit{Restore} indicator is an FSTN with its \textit{Back Path Link Pointer.T-bit} set to one.
- A \textit{Restore} FSTN may be matched to one or more \textit{Save-Place} FSTNs. For example, if the schedule includes a poll-rate 1 level, then system software only needs to place a \textit{Restore} FSTN at the beginning of this list in order to match all possible \textit{Save-Place} FSTNs.
- If the schedule does not have elements linked at a poll-rate level of one, and one or more \textit{Save-Place} FSTNs are used, then System Software must ensure the \textit{Restore} FSTN's \textit{Normal Path Link Pointer's T-bit} is set to one, as this is used to mark the end of the periodic list.
- When the schedule does have elements linked at a poll rate level of one, a \textit{Restore} FSTN must be the first data structure on the poll rate one list. All traversal paths from the frame list converge on the poll-rate one list. System software must ensure that \textit{Recovery Path} mode is exited before the host controller is allowed to traverse the poll rate level one list.
- A \textit{Save-Place} FSTN's \textit{Back Path Link Pointer} must reference a queue head data structure. The referenced queue head must be reachable from the previous frame list.
location. In other words, if the Save-Place FSTN is reachable from frame list offset N, then the FSTN's Back Path Link Pointer must reference a queue head that is reachable from frame list offset N-1.

Software should make the schedule as efficient as possible. What this means in this context is that software should have no more than one Save-Place FSTN reachable in any single frame. Note there is times when two (or more, depending on the implementation) could exist as full/low-speed footprints change with bandwidth adjustments. This could occur, for example when a bandwidth re-balance causes system software to move the Save-Place FSTN from one poll rate level to another. During the transition, software must preserve the integrity of the previous schedule until the new schedule is in place.

42.5.3.12.2.4 Tracking Split Transaction Progress for Interrupt Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where data is lost.

For interrupt-IN transfers, data is lost when it makes it into the USB 2.0 hub, but the USB 2.0 host system is unable to get it from the USB 2.0 Hub and into the system before it expires from the transaction translator pipeline.

When a lost data condition is detected, the queue must be halted, thus signaling system software to recover from the error. A data-loss condition exists whenever a start-split is issued, accepted and successfully executed by the USB 2.0 Hub, but the complete-splits get unrecoverable errors on the high-speed link, or the complete-splits do not occur at the correct times. One reason complete-splits might not occur at the right time would be due to host-induced system hold-offs that cause the host controller to miss bus transactions because it cannot get timely access to the schedule in system memory.

The same condition can occur for an interrupt-OUT, but the result is not an endpoint halt condition, but rather effects only the progress of the transfer. The queue head has the following fields to track the progress of each split transaction. These fields are used to keep incremental state about which (and when) portions have been executed.

- **C-prog-mask.** This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. **C-prog-mask** is a simple bit-vector that the host controller sets one of the C-prog-mask bits for each complete-split executed. The bit position is determined by the micro-frame number in which the complete-split was executed. The host controller always checks **C-prog-mask** before executing a
complete-split transaction. If the previous complete-splits have not been executed then it means one (or more) have been skipped and data has potentially been lost.

- **FrameTag.** This field is used by the host controller during the complete-split portion of the split transaction to tag the queue head with the frame number (*H-Frame number*) when the next complete split must be executed.

- **S-bytes.** This field can be used to store the number of data payload bytes sent during the start-split (if the transaction was an OUT). The *S-bytes* field must be used to accumulate the data payload bytes received during the complete-splits (for an IN).

### 42.5.3.12.2.5 Split Transaction Execution State Machine for Interrupt

In the following presentation, all references to micro-frame are in the context of a micro-frame within an *H-Frame*.

As with asynchronous Full- and Low-speed endpoints, a split-transaction state machine is used to manage the split transaction sequence.

Aside from the fields defined in the queue head for scheduling and tracking the split transaction, the host controller calculates one internal mechanism that is also used to manage the split transaction. The internal calculated mechanism is:

- **cMicroFrameBit** is a single-bit encoding of the current micro-frame number. It is an eight-bit value calculated by the host controller at the beginning of every micro-frame. It is calculated from the three least significant bits of the *FRINDEX* register (that is, \( c_{MicroFrameBit} = 1 \text{ shifted-left}(FRINDEX[2:0]) \)). The *cMicroFrameBit* has at most one bit asserted, which always corresponds to the current micro-frame number. For example, if the current micro-frame is 0, then *cMicroFrameBit* will equal 00000001b. The variable *cMicroFrameBit* is used to compare against the *S-mask* and *C-mask* fields to determine whether the queue head is marked for a start- or complete-split transaction for the current micro-frame.

The following figure illustrates the state machine for managing a complete interrupt split transaction. There are two phases to each split transaction. The first is a single start-split transaction, which occurs when the *SplitXState* is at Do_Start and the single bit in *cMicroFrameBit* has a corresponding bit active in *QH.S-mask*. The transaction translator does not acknowledge the receipt of the periodic start-split, so the host controller unconditionally transitions the state to Do_Complete. Due to the available jitter in the transaction translator pipeline, there will be more than one complete-split transaction scheduled by software for the Do_Complete state. This translates simply to the fact that there are multiple bits set to a one in the *QH.C-mask* field.

The host controller keeps the queue head in the Do_Complete state until the split transaction is complete (see definition below), or an error condition triggers the *three-strikes-rule* (for example, after the host tries the same transaction three times, and each
encounters an error, the host controller will stop retrying the bus transaction and halt the endpoint, thus requiring system software to detect the condition and perform system-dependent recovery).

![Diagram of Split Transaction State Machine for Interrupt]

Figure 42-23. Split Transaction State Machine for Interrupt

See Previous Section for the frame tag management rules.

Periodic Interrupt - Do Start Split

This is the state software must initialize a full- or low-speed interrupt queue head StartXState bit. This state is entered from the Do_Complete Split state only after the split transaction is complete. This occurs when one of the following events occur: The transaction translator responds to a complete-split transaction with one of the following:

- NAK. A NAK response is a propagation of the full- or low-speed endpoint's NAK response.
- ACK. An ACK response is a propagation of the full- or low-speed endpoint's ACK response. Only occurs on an OUT endpoint.
- DATA 0/1. Only occurs for INs. Indicates that this is the last of the data from the endpoint for this split transaction.
- ERR. The transaction on the low-/full-speed link below the transaction translator had a failure (for example, timeout, bad CRC, etc.).
- NYET (and Last). The host controller issued the last complete-split and the transaction translator responded with a NYET handshake. This means that the start-split was not correctly received by the transaction translator, so it never executed a transaction to the full- or low-speed endpoint, see Section Periodic Isochronous - Do Complete Split for the definition of 'Last'.

![Diagram of Start Split State Machine]

USB Operation Model

i.MX RT1060 Processor Reference Manual, Rev. 2, 12/2019

NXP Semiconductors
Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it performs the following test to determine whether to execute a start-split.

- **QH.S-mask** is bit-wise anded with **cMicroFrameBit**.

If the result is non-zero, then the host controller will issue a start-split transaction. If the **PIDCode** field indicates an IN transaction, the host controller must zero-out the **QH.S-bytes** field. After the split-transaction has been executed, the host controller sets up state in the queue head to track the progress of the complete-split phase of the split transaction. Specifically, it records the expected frame number into **QH.FrameTag** field (see Section ), set **C-prog-mask** to zero (00h), and exits this state. Note that the host controller must not adjust the value of **CErr** as a result of completion of a start-split transaction.

**Periodic Interrupt - Do Complete Split**

This state is entered unconditionally from the Do Start Split state after a start-split transaction is executed on the bus. Each time the host controller visits a queue head in this state (once within the Execute Transaction state), it checks to determine whether a complete-split transaction should be executed now.

There are four tests to determine whether a complete-split transaction should be executed.

- **Test A.** **cMicroFrameBit** is bit-wise anded with **QH.C-mask** field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame.
- **Test B.** **QH.FrameTag** is compared with the current contents of **FRINDEX[7:3]**. An equal indicates a match.
- **Test C.** The complete-split progress bit vector is checked to determine whether the previous bit is set, indicating that the previous complete-split was appropriately executed. An example algorithm for this test is provided below:

```plaintext
Algorithm Boolean CheckPreviousBit(QH.C-prog-mask, QH.C-mask, cMicroFrameBit)
Begin
    -- Return values:
    -- TRUE - no error
    -- FALSE - error
    --
    Boolean rvalue = TRUE;
    previousBit = cMicroFrameBit logical-rotate-right(1)
    -- Bit-wise anding previousBit with C-mask indicates
    -- whether there was an intent
    -- to send a complete split in the previous micro-frame. So,
    -- if the
    -- 'previous bit' is set in C-mask, check C-prog-mask to
    -- make sure it
    -- happened.
    If (previousBit bitAND QH.C-mask) then
        If not(previousBit bitAND QH.C-prog-mask) then
            rvalue = FALSE;
        End if
    End if
    -- If the C-prog-mask already has a one in this bit position,
```

**Chapter 42 Universal Serial Bus Controller (USB)**

NXP Semiconductors
-- then an aliasing
-- error has occurred. It will probably get caught by the
-- FrameTag Test, but
-- at any rate it is an error condition that as detectable here
-- should not allow
-- a transaction to be executed.
If (cMicroFrameBit bitAND QH.C-prog-mask) then
rvalue = FALSE;
End if
return (rvalue)
End Algorithm

• Test D. Check to see if a start-split should be executed in this micro-frame. Note this
is the same test performed in the Do Start Split state (see Section Periodic
Isochronous - Do Start Split ). Whenever it evaluates to TRUE and the controller is
NOT processing in the context of a Recovery Path mode, it means a start-split should
occur in this micro-frame. Test D and Test A evaluating to TRUE at the same time is
a system software error. Behavior is undefined.

If (A .and. B .and. C .and. not(D)) then the host controller will execute a complete-split
transaction. When the host controller commits to executing the complete-split transaction,
it updates QH.C-prog-mask by bit-ORing with cMicroFrameBit. On completion of the
complete-split transaction, the host controller records the result of the transaction in the
queue head and sets QH.FrameTag to the expected H-Frame number (see Section ). The
effect to the state of the queue head and thus the state of the transfer depends on the
response by the transaction translator to the complete-split transaction. The following
responses have the effects (note that any responses that result in decrementing of the
CErr will result in the queue head being halted by the host controller if the result of the
decrement is zero):

• NYET (and Last). On each NYET response, the host controller checks to determine
whether this is the last complete-split for this split transaction. Last is defined in this
context as the condition where all of the scheduled complete-splits have been
executed. If it is the last complete-split (with a NYET response), then the transfer
state of the queue head is not advanced (never received any data) and this state
exited. The transaction translator must have responded to all the complete-splits with
NYETs, meaning that the start-split issued by the host controller was not received.
The start-split should be retried at the next poll period.
• The test for whether this is the Last complete split can be performed by XOR QH.C-
mask with QH.C-prog-mask. If the result is all zeros then all complete-splits have
been executed. When this condition occurs, the XactErr status bit is set to a one and
the CErr field is decremented.
• NYET (and not Last). See above description for testing for Last. The complete-split
transaction received a NYET response from the transaction translator. Do not update
any transfer state (except for C-prog-mask and FrameTag) and stay in this state. The
host controller must not adjust CErr on this response.
• Transaction Error (XactErr). Timeout, data CRC failure, etc. The CErr field is decremented and the XactErr bit in the Status field is set to a one. The complete split transaction is immediately retried (if Cerr is non-zero). If there is not enough time in the micro-frame to complete the retry and the endpoint is an IN, or CErr is decremented to a zero from a one, the queue is halted. If there is not enough time in the micro-frame to complete the retry and the endpoint is an OUT and CErr is not zero, then this state is exited (that is, return to Do Start Split). This results in a retry of the entire OUT split transaction, at the next poll period. Refer to Chapter 11 Hubs (specifically the section full- and low-speed Interrupts) in the USB Specification Revision 2.0 for detailed requirements on why these errors must be immediately retried.

• ACK. This can only occur if the target endpoint is an OUT. The target endpoint ACK'd the data and this response is a propagation of the endpoint ACK up to the host controller. The host controller must advance the state of the transfer. The Current Offset field is incremented by Maximum Packet Length or Bytes to Transfer, whichever is less. The field Bytes To Transfer is decremented by the same amount. And the data toggle bit (dt) is toggled. The host controller will then exit this state for this queue head. The host controller must reload CErr with maximum value on this response. Advancing the transfer state may cause other process events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).

• MDATA. This response will only occur for an IN endpoint. The transaction translator responded with zero or more bytes of data and an MDATA PID. The incremental number of bytes received is accumulated in QH.S-bytes. The host controller must not adjust CErr on this response.

• DATA0/1. This response may only occur for an IN endpoint. The number of bytes received is added to the accumulated byte count in QH.S-bytes. The state of the transfer is advanced by the result and the host controller will exit this state for this queue head.

• Advancing the transfer state may cause other processing events such as retirement of the qTD and advancement of the queue (see Section Managing Control/Bulk/Interrupt Transfers through Queue Heads).

• If the data sequence PID does not match the expected, the entirety of the data received in this split transaction is ignored, the transfer state is not advanced and this state is exited.

• NAK. The target endpoint Nak'd the full- or low-speed transaction. The state of the transfer is not advanced, and this state is exited. The host controller must reload CErr with maximum value on this response.
• ERR. There was an error during the full- or low-speed transaction. The ERR status bit is set to a one, \( C_{err} \) is decremented, the state of the transfer is not advanced, and this state is exited.

• STALL. The queue is halted (an exit condition of the Execute Transaction state). The status field bits: Active bit is set to zero and the Halted bit is set to a one and the qTD is retired. Responses which are not enumerated in the list or which are received out of sequence are illegal and may result in undefined host controller behavior. The other possible combinations of tests A, B, C, and D may indicate that data or response was lost. The table below lists the possible combinations and the appropriate action.

Managing QH.FrameTag Field

The `QH.FrameTag` field in a queue head is completely managed by the host controller. The rules for setting `QH.FrameTag` are simple:

- **Rule 1:** If transitioning from Do Start Split to Do Complete Split and the current value of `FRINDEX[2:0]` is 6, `QH.FrameTag` is set to `FRINDEX[7:3] + 1`. This accommodates split transactions whose start-split and complete-splits are in different H-Frames (case 2a, see Figure 42-20).
- **Rule 2:** If the current value of `FRINDEX[2:0]` is 7, `QH.FrameTag` is set to `FRINDEX[7:3] + 1`. This accommodates staying in Do Complete Split for cases 2a, 2b, and 2c (Figure 42-20).
- **Rule 3:** If transitioning from Do_Start Split to Do Complete Split and the current value of `FRINDEX[2:0]` is not 6, or currently in Do Complete Split and the current value of `(FRINDEX[2:0])` is not 7, `FrameTag` is set to `FRINDEX[7:3]`. This accommodates all other cases (Figure 42-20).

### 42.5.3.12.2.6 Rebalancing the periodic schedule

System software must occasionally adjust a periodic queue head's S-mask and C-mask fields during operation.

This need occurs when adjustments to the periodic schedule create a new bandwidth budget and one or more queue head's are assigned new execution footprints (that is, new S-mask and C-mask values).

It is imperative that System software must not update these masks to new values in the midst of a split transaction. In order to avoid any race conditions with the update, the EHCI host controller provides a simple assist to system software. System software sets the `Inactivate-on-next-Transaction (I)` bit to a one to signal the host controller that it intends to update the S-mask and C-mask on this queue head. System software will then wait for the host controller to observe the `I-bit` is a one and transition the `Active` bit to a zero. The rules for how and when the host controller sets the `Active` bit to zero are enumerated below:

- **If the `Active` bit is a zero, no action is taken.** The host controller does not attempt to advance the queue when the `I-bit` is a one.
- **If the `Active` bit is a one and the `SplitXState` is DoStart (regardless of the value of S-mask),** the host controller will simply set `Active` bit to a zero. The host controller is
not required to write the transfer state back to the current qTD. Note that if the S-mask indicates that a start-split is scheduled for the current micro-frame, the host controller must not issue the start-split bus transaction. It must set the Active bit to zero.

System software must save transfer state before setting the I-bit to a one. This is required so that it can correctly determine what transfer progress (if any) occurred after the I-bit was set to a one and the host controller executed its final bus-transaction and set Active to a zero.

After system software has updated the S-mask and C-mask, it must then reactivate the queue head. Because the Active bit and the I-bit cannot be updated with the same write, system software needs to use the following algorithm to coherently re-activate a queue head that has been stopped via the I-bit.

1. Set the Halted bit to a one, then
2. Set the I-bit to a zero, then
3. Set the Active bit to a one and the Halted bit to a zero in the same write.

Setting the Halted bit to a one inhibits the host controller from attempting to advance the queue between the time the I-bit goes to a zero and the Active bit goes to a one.

### 42.5.3.12.3 Split Transaction Isochronous

Full-speed isochronous transfers are managed using the split-transaction protocol through a USB 2.0 transaction translator in a USB2.0 Hub. The EHCI controller utilizes siTD data structure to support the special requirements of isochronous split-transactions.

This data structure uses the scheduling model of isochronous TDs (iTD, Section Isochronous (High-Speed) Transfer Descriptor (iTD)) (see Section Managing Isochronous Transfers Using iTDs for the operational model of iTDs) with the contiguous data feature provided by queue heads. This simple arrangement allows a single isochronous scheduling model and adds the additional feature that all data received from the endpoint (per split transaction) must land into a contiguous buffer.

#### 42.5.3.12.3.1 Split Transaction Scheduling Mechanisms for Isochronous

Full-speed isochronous transactions are managed through a transaction translator's periodic pipeline. As with full- and low-speed interrupt, system software manages each transaction translator's periodic pipeline by budgeting and scheduling exactly during which micro-frames the start-splits and complete-splits for each full-speed isochronous endpoint occur.
The requirements described in Section Split Transaction Scheduling Mechanisms for Interrupt apply. The following figure illustrates the general scheduling boundary conditions that are supported by the EHCI periodic schedule. The $S_X$ and $C_X$ labels indicate micro-frames where software can schedule start- and complete-splits (respectively). The $H$-Frame boundaries are marked with a large, solid bold vertical line. The $B$-Frame boundaries are marked with a large, bold, dashed line. The bottom of the figure illustrates the relationship of an siTD to the $H$-Frame.

### Figure 42-24. Split Transaction, Isochronous Scheduling Boundary Conditions

When the endpoint is an isochronous OUT, there are only start-splits, and no complete-splits. When the endpoint is an isochronous IN, there is at most one start-split and one to $N$ complete-splits. The scheduling boundary cases are:

- **Case 1**: The entire split transaction is completely bounded by an $H$-Frame. For example: the start-splits and complete-splits are all scheduled to occur in the same $H$-Frame.
Case 2a: This boundary case is where one or more (at most two) complete-splits of a split transaction IN are scheduled across an $H$-Frame boundary. This can only occur when the split transaction has the possibility of moving data in $B$-Frame, micro-frames 6 or 7 ($H$-Frame micro-frame 7 or 0). When an $H$-Frame boundary wrap condition occurs, the scheduling of the split transaction spans more than one location in the periodic list. (For example, it takes two siTDs in adjacent periodic frame list locations to fully describe the scheduling for the split transaction.)

Although the scheduling of the split transaction may take two data structures, all of the complete-splits for each full-speed IN isochronous transaction must use only one data pointer. For this reason, siTDs contain a back pointer, the use of which is described below.

Software must never schedule full-speed isochronous OUTs across an $H$-Frame boundary.

Case 2b: This case can only occur for a very large isochronous IN. It is the only allowed scenario where a start-split and complete-split for the same endpoint can occur in the same micro-frame. Software must enforce this rule by scheduling the large transaction first. Large is defined to be anything larger than 579 byte maximum packet size.

A subset of the same mechanisms employed by full- and low-speed interrupt queue heads are employed in siTDs to schedule and track the portions of isochronous split transactions. The following fields are initialized by system software to instruct the host controller when to execute portions of the split transaction protocol.

- $SplitXState$. This is a single bit residing in the $Status$ field of an siTD (see Figure 42-25). This bit is used to track the current state of the split transaction. The rules for managing this bit are described in Section Split Transaction Execution State Machine for Interrupt.

- $Frame S-mask$. This is a bit-field where system software sets a bit corresponding to the micro-frame (within an $H$-Frame) that the host controller should execute a start-split transaction. This is always qualified by the value of the $SplitXState$ bit. For example, referring to the IN example in Figure 42-24, case one, the $S-mask$ would have a value of 0000001b indicating that if the siTD is traversed by the host controller, and the $SplitXState$ indicates Do Start Split, and the current micro-frame as indicated by USB_n_FRINDEX[2:0] is 0, then execute a start-split transaction.

- $Frame C-mask$. This is a bit-field where system software sets one or more bits corresponding to the micro-frames (within an $H$-Frame) that the host controller should execute complete-split transactions. The interpretation of this field is always qualified by the value of the $SplitXState$ bit. For example, referring to the IN example in Figure 42-24, case one, the $C-mask$ would have a value of 00111100b indicating that if the siTD is traversed by the host controller, and the $SplitXState$ indicates Do
Complete Split, and the current micro-frame as indicated by $USB_n_FRINDEX[2:0]$ is 2, 3, 4, or 5, then execute a complete-split transaction.

- **Back Pointer.** This field in a siTD is used to complete an IN split-transaction using the previous $H-Frame$'s siTD. This is only used when the scheduling of the complete-splits span an $H-Frame$ boundary.

There exists a one-to-one relationship between a high-speed isochronous split transaction (including all start- and complete-splits) and one full-speed isochronous transaction. An siTD contains (amongst other things) buffer state and split transaction scheduling information. An siTD's buffer state always maps to one full-speed isochronous data payload. This means that for any full-speed transaction payload, a single siTD's data buffer must be used. This rule applies to both IN an OUTs. An siTD's scheduling information usually also maps to one high-speed isochronous split transaction. The exception to this rule is the $H-Frame$ boundary wrap cases mentioned above.

The siTD data structure describes at most, one frame's worth of high-speed transactions and that description is strictly bounded within a frame boundary. The figure below illustrates some examples. On the top are examples of the full-speed transaction footprints for the boundary scheduling cases described above. In the middle are time-frame references for both the $B-Frames$ (HS/FS/LS Bus) and the $H-Frames$. On the bottom is illustrated the relationship between the scope of an siTD description and the time references. Each $H-Frame$ corresponds to a single location in the periodic frame list. The implication is that each siTD is reachable from a single periodic frame list location at a time.
Each case is described below:

- **Case 1**: One siTD is sufficient to describe and complete the isochronous split transaction because the whole isochronous split transaction is tightly contained within a single *H-Frame*.

- **Case 2a, 2b**: Although both INs and OUTs can have these footprints, OUTs always take only one siTD to schedule. However, INs (for these boundary cases) require two siTDs to complete the scheduling of the isochronous split transaction $siTD_X$ is used to always issue the start-split and the first $N$ complete-splits. The full-speed transaction (for these cases) can deliver data on the full-speed bus segment during micro-frame 7 of $H-Frame_{Y+1}$, or micro-frame 0 of $H-Frame_{Y+2}$. The complete splits are scheduled using $siTD_{X+2}$ (not shown). The complete-splits to extract this data must use the buffer pointer from $siTD_{X+1}$. The only way for the host controller to reach $siTD_{X+1}$ from $H-Frame_{Y+2}$ is to use $siTD_{X+2}$’s back pointer. The host controller rules for when to use the back pointer are described in Section *Periodic Isochronous - Do Complete Split*.

Software must apply the following rules when calculating the schedule and linking the schedule data structures into the periodic schedule:
• Software must ensure that an isochronous split-transaction is started so that it will complete before the end of the B-Frame.
• Software must ensure that for a single full-speed isochronous endpoint, there is never a start-split and complete-split in H-Frame, micro-frame 1. This is mandated as a rule so that case 2a and case 2b can be discriminated. According to the core USB specification, the long isochronous transaction illustrated in Case 2b, could be scheduled so that the start-split was in micro-frame 1 of H-Frame N and the last complete-split would need to occur in micro-frame 1 of H-Frame N+1. However, it is impossible to discriminate between cases 2a and case 2b, which has significant impact on the complexity of the host controller.

42.5.3.12.3.2 Tracking Split Transaction Progress for Isochronous Transfers

To correctly maintain the data stream, the host controller must be able to detect and report errors where device to host data is lost. Isochronous endpoints do not employ the concept of a halt on error, however the host is required to identify and report per-packet errors observed in the data stream. This includes schedule traversal problems (skipped micro-frames), timeouts and corrupted data received.

In similar kind to interrupt split-transactions, the portions of the split transaction protocol must execute in the micro-frames they are scheduled. The queue head data structure used to manage full- and low-speed interrupt has several mechanisms for tracking when portions of a transaction have occurred. Isochronous transfers use siTDs, for their transfers, and the data structures are only reachable via the schedule in the exact micro-frame in which they are required (so all the mechanism employed for tracking in queue heads is not required for siTDs). Software has the option of reusing siTD several times in the complete periodic schedule. However, it must ensure that the results of split transaction N are consumed and the siTD reinitialized (activated) before the host controller gets back to the siTD (in a future micro-frame).

Split-transaction isochronous OUTs utilize a low-level protocol to indicate which portions of the split transaction data have arrived. Control over the low-level protocol is exposed in an siTD via the fields Transaction Position (TP) and Transaction Count (T-count). If the entire data payload for the OUT split transaction is larger than 188 bytes, there will be more than one start-split transaction, each of which require proper annotation. If host hold-offs occur, then the sequence of annotations received from the host will not be complete, which is detected and handled by the transaction translator. See Section Periodic Isochronous - Do Start Split for a description on how these fields are used during a sequence of start-split transactions.

The fields siTD.T-Count and siTD.TP are used by the host controller to drive and sequence the transaction position annotations. It is the responsibility of system software to properly initialize these fields in each siTD. Once the budget for a split-transaction
isochronous endpoint is established, $S$-mask, $T$-Count, and $TP$ initialization values for all the siTD associated with the endpoint are constant. They remain constant until the budget for the endpoint is recalculated by software and the periodic schedule adjusted.

For IN-endpoints, the transaction translator simply annotates the response data packets with enough information to allow the host controller to identify the last data. As with split transaction Interrupt, it is the host controller's responsibility to detect when it has missed an opportunity to execute a complete-split. The following field in the siTD is used to track and detect errors in the execution of a split transaction for an IN isochronous endpoint.

- **C-prog-mask.** This is an eight-bit bit-vector where the host controller keeps track of which complete-splits have been executed. Due to the nature of the Transaction Translator periodic pipeline, the complete-splits need to be executed in-order. The host controller needs to detect when the complete-splits have not been executed in order. This can only occur due to system hold-offs where the host controller cannot get to the memory-based schedule. **C-prog-mask** is a simple bit-vector that the host controller sets a bit for each complete-split executed. The bit position is determined by the micro-frame (USB_n_FRINDEX[2:0]) number in which the complete-split was executed. The host controller always checks **C-prog-mask** before executing a complete-split transaction. If the previous complete-splits have not been executed, then it means one (or more) have been skipped and data has potentially been lost. System software is required to initialize this field to zero before setting an siTD's **Active** bit to a one.

If a transaction translator returns with the final data before all of the complete-splits have been executed, the state of the transfer is advanced so that the remaining complete-splits are not executed. Refer to Section Asynchronous - Do Complete Split for a description on how the state of the transfer is advanced. It is important to note that an IN siTD is retired based solely on the responses from the Transaction Translator to the complete-split transactions. This means, for example, that it is possible for a transaction translator to respond to a complete-split with an MDATA PID. The number of bytes in the MDATA's data payload could cause the siTD field **Total Bytes to Transfer** to decrement to zero. This response can occur, before all of the scheduled complete-splits have been executed. In other interface, data structures (for example, high-speed data streams through queue heads), the transition of **Total Bytes to Transfer** to zero signals the end of the transfer and results in setting of the **Active** bit to zero. However, in this case, the result has not been delivered by the Transaction Translator and the host must continue with the next complete-split transaction to extract the residual transaction state. This scenario occurs because of the pipeline rules for a Transaction Translator (see Chapter 11 of the Universal Serial Bus Revision 2.0). In summary the periodic pipeline rules require that on a micro-frame boundary, the Transaction Translator will hold the final two bytes received (if it has not seen an End Of Packet (EOP)) in the full-speed bus pipe stage and give the
remaining bytes to the high-speed pipeline stage. At the micro-frame boundary, the Transaction Translator could have received the entire packet (including both CRC bytes) but not received the packet EOP. In the next micro-frame, the Transaction Translator will respond with an MDATA and send all of the data bytes (with the two CRC bytes being held in the full-speed pipeline stage). This could cause the siTD to decrement its Total Bytes to Transfer field to zero, indicating it has received all expected data. The host must still execute one more (scheduled) complete-split transaction in order to extract the results of the full-speed transaction from the Transaction Translator (for example, the Transaction Translator may have detected a CRC failure, and this result must be forwarded to the host).

If the host experiences hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous OUT, then the protocol to the transaction translator will not be consistent and the transaction translator will detect and react to the problem. Likewise, for host hold-offs that cause the host controller to skip one or more (but not all) scheduled split transactions for an isochronous IN, the C-prog-mask is used by the host controller to detect errors. However, if the host experiences a hold-off that causes it to skip all of an siTD, or an siTD expires during a host hold off (for example, a hold-off occurs and the siTD is no longer reachable by the host controller in order for it to report the hold-off event), then system software must detect that the siTDs have not been processed by the host controller (that is, state not advanced) and report the appropriate error to the client driver.

42.5.3.12.3.3 Split Transaction Execution State Machine for Isochronous

In the following presentation, all references to micro-frame are in the context of a micro-frame within an H-Frame.

If the Active bit in the Status byte is a zero, the host controller will ignore the siTD and continue traversing the periodic schedule. Otherwise the host controller will process the siTD as specified below. A split transaction state machine is used to manage the split-transaction protocol sequence. The host controller uses the fields defined in Section Tracking Split Transaction Progress for Interrupt Transfers, plus the variable cMicroFrameBit defined in Section Split Transaction Execution State Machine for Interrupt to track the progress of an isochronous split transaction. The figure below illustrates the state machine for managing an siTD through an isochronous split transaction. Bold, dotted circles denote the state of the Active bit in the Status field of a siTD. The Bold, dotted arcs denote the transitions between these states. Solid circles denote the states of the split transaction state machine and the solid arcs denote the transitions between these states. Dotted arcs and boxes reference actions that take place either as a result of a transition or from being in a state.
**Figure 42-26. Split Transaction State Machine for Isochronous**

### 42.5.3.12.3.4 Periodic Isochronous - Do Start Split

Isochronous split transaction OUTs use only this state.

An siTD for a split-transaction isochronous IN is either initialized to this state, or the siTD transitions to this state from Do Complete Split when a case 2a (IN) or 2b scheduling boundary isochronous split-transaction completes.

Each time the host controller reaches an active siTD in this state, it checks the *siTD.S-mask* against *cMicroFrameBit*. If there is a one in the appropriate position, the siTD will execute a start-split transaction. By definition, the host controller cannot *reach* an siTD at the wrong time. If the *I/O* field indicates an IN, then the start-split transaction includes only the extended token plus the full-speed token. Software must initialize the *siTD.Total Bytes To Transfer* field to the number of bytes expected. This is usually the maximum packet size for the full-speed endpoint. The host controller exits this state when the start-split transaction is complete.

The remainder of this section is specific to an isochronous OUT endpoint (that is, the *I/O* field indicates an OUT). When the host controller executes a start-split transaction for an isochronous OUT it includes a data payload in the start-split transaction. The memory
buffer address for the data payload is constructed by concatenating $siTD.Current\ Offset$ with the page pointer indicated by the page selector field ($siTD.P$). A zero in this field selects Page 0 and a 1 selects Page 1. During the start-split for an OUT, if the data transfer crosses a page boundary during the transaction, the host controller must detect the page cross, update the $siTD.P$-bit from a zero to a one, and begin using the $siTD.Page$ with $siTD.Current\ Offset$ as the memory address pointer. The field $siTD.TP$ is used to annotate each start-split transaction with the indication of which part of the split-transaction data the current payload represents (ALL, BEGIN, MID, END). In all cases the host controller simply uses the value in $siTD.TP$ to mark the start-split with the correct transaction position code.

$T-Count$ is always initialized to the number of start-splits for the current frame. $TP$ is always initialized to the first required transaction position identifier. The scheduling boundary case (see Figure 42-25) is used to determine the initial value of $TP$. The initial cases are summarized in the following table.

<table>
<thead>
<tr>
<th>Case</th>
<th>T-count</th>
<th>TP</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1, 2a</td>
<td>=1</td>
<td>ALL</td>
<td>When the OUT data payload is less than (or equal to) 188 bytes, only one start-split is required to move the data. The one start-split must be marked with an ALL.</td>
</tr>
<tr>
<td>1, 2a</td>
<td>!=1</td>
<td>BEGIN</td>
<td>When the OUT data payload is greater than 188 bytes more than one start-split must be used to move the data. The initial start-split must be marked with a BEGIN.</td>
</tr>
</tbody>
</table>

After each start-split transaction is complete, the host controller updates $T-Count$ and $TP$ appropriately so that the next start-split is correctly annotated.

The table below illustrates all of the $TP$ and $T-count$ transitions, which must be accomplished by the host controller.

<table>
<thead>
<tr>
<th>TP</th>
<th>T-count next</th>
<th>TP next</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ALL</td>
<td>0</td>
<td>N/A</td>
<td>Transition from ALL, to done.</td>
</tr>
<tr>
<td>BEGIN</td>
<td>1</td>
<td>END</td>
<td>Transition from BEGIN to END. Occurs when $T-count$ starts at 2.</td>

</table>
The start-split transactions do not receive a handshake from the transaction translator, so the host controller always advances the transfer state in the siTD after the bus transaction is complete. To advance the transfer state the following operations take place:

- The \textit{siTD.Total Bytes To Transfer} and the \textit{siTD.Current Offset} fields are adjusted to reflect the number of bytes transferred.
- The \textit{siTD.P} (page selector) bit is updated appropriately.
- The \textit{siTD.TP} and \textit{siTD.T-count} fields are updated appropriately as defined in Table 42-50.

These fields are then written back to the memory based siTD. The \textit{S-mask} is fixed for the life of the current budget. As mentioned above, \textit{TP} and \textit{T-count} are set specifically in each siTD to reflect the data to be sent from this siTD. Therefore, regardless of the value of \textit{S-mask}, the actual number of start-split transactions depends on \textit{T-count} (or equivalently, Total Bytes to Transfer). The host controller must set the \textit{Active} bit to a zero when it detects that all of the schedule data has been sent to the bus. The preferred method is to detect when \textit{T-Count} decrements to zero as a result of a start-split bus transaction. Equivalently, the host controller can detect when Total Bytes to Transfer decrements to zero. Either implementation must ensure that if the initial condition is Total Bytes to Transfer equal to zero and \textit{T-count} is equal to a one, then the host controller will issue a single start-split, with a zero-length data payload. Software must ensure that \textit{TP}, \textit{T-count} and Total Bytes to Transfer are set to deliver the appropriate number of bus transactions from each siTD. An inconsistent combination will yield undefined behavior.

If the host experiences hold-offs that cause the host controller to skip start-split transactions for an OUT transfer, the state of the transfer will not progress appropriately. The transaction translator will observe protocol violations in the arrival of the start-splits for the OUT endpoint (that is, the transaction position annotation will be incorrect as received by the transaction translator).

Example scenarios are described in Section \textit{Split Transaction for Isochronous - Processing Examples}.

A host controller implementation can optionally track the progress of an OUT split transaction by setting appropriate bits in the \textit{siTD.C-prog-mask} as it executes each scheduled start-split. The \textit{checkPreviousBit()} algorithm defined in \textit{Periodic Isochronous - Do Complete Split} can be used prior to executing each start-split to determine whether start-splits were skipped. The host controller can use this mechanism to detect missed micro-frames. It can then set the siTD's \textit{Active} bit to zero and stop execution of this siTD. This saves on both memory and high-speed bus bandwidth.
42.5.3.12.3.5 Periodic Isochronous - Do Complete Split

This state is only used by a split-transaction isochronous IN endpoint.

This state is entered unconditionally from the Do Start State after a start-split transaction is executed for an IN endpoint. Each time the host controller visits an siTD in this state, it conducts a number of tests to determine whether it should execute a complete-split transaction. The individual tests are listed below. The sequence they are applied depends on which micro-frame the host controller is currently executing which means that the tests might not be applied until after the siTD referenced from the back pointer has been fetched.

- Test A. `cMicroFrameBit` is bit-wise anded with `siTD.C-mask` field. A non-zero result indicates that software scheduled a complete-split for this endpoint, during this micro-frame. This test is always applied to a newly fetched siTD that is in this state.
- Test B. The `siTD.C-prog-mask` bit vector is checked to determine whether the previous complete splits have been executed. An example algorithm is below (this is slightly different than the algorithm used in Section Periodic Isochronous - Do Complete Split). The sequence in which this test is applied depends on the current value of `USB_n_FRINDEX[2:0]`. If `USB_n_FRINDEX[2:0]` is 0 or 1, it is not applied until the back pointer has been used. Otherwise it is applied immediately.

```
Algorithm Boolean CheckPreviousBit(siTD.C-prog-mask, siTD.C-mask, cMicroFrameBit)
Begin
    Boolean rvalue = TRUE;
    previousBit = cMicroFrameBit rotate-right(1)
    -- Bit-wise anding previousBit with C-mask indicates whether there was an intent
    -- to send a complete split in the previous micro-frame. So, if the
    -- 'previous bit' is set in C-mask, check C-prog-mask to make sure it
    -- happened.
    if previousBit bitAND siTD.C-mask then
        if not (previousBit bitAND siTD.C-prog-mask) then
            rvalue = FALSE
        End if
    End if
    Return rvalue
End Algorithm
```

If Test A is true and `USB_n_FRINDEX[2:0]` is zero or one, then this is a case 2a or 2b scheduling boundary (see Figure 42-24). See Section Periodic Isochronous - Do Complete Split for details in handling this condition.

If Test A and Test B evaluate to true, then the host controller will execute a complete-split transaction using the transfer state of the current siTD. When the host controller commits to executing the complete-split transaction, it updates `QH.C-prog-mask` by bit-ORing with `cMicroFrameBit`. The transfer state is advanced based on the completion status of the complete-split transaction. To advance the transfer state of an IN siTD, the host controller must:

- Decrement the number of bytes received from `siTD>Total Bytes To Transfer`,
- Adjust `siTD.Current Offset` by the number of bytes received,
• Adjust \( siTD.P \) (page selector) field if the transfer caused the host controller to use the next page pointer, and
• Set any appropriate bits in the \( siTD.Status \) field, depending on the results of the transaction.

Note that if the host controller encounters a condition where \( siTD.Total\ Bytes\ To\ Transfer \) is zero, and it receives more data, the host controller must not write the additional data to memory. The \( siTD.Status.Active \) bit must be set to zero and the \( siTD.Status.Babble\ Detected \) bit must be set to a one. The fields \( siTD.Total\ Bytes\ To\ Transfer, siTD.Current\ Offset, \) and \( siTD.P \) (page selector) are not required to be updated as a result of this transaction attempt.

The host controller must accept (assuming good data packet CRC and sufficient room in the buffer as indicated by the value of \( siTD.Total\ Bytes\ To\ Transfer \)) MDATA and DATA0/1 data payloads up to and including 192 bytes. A host controller implementation may optionally set \( siTD.Status\ Active \) to a zero and \( siTD.Status.Babble\ Detected \) to a one when it receives and MDATA or DATA0/1 with a data payload of more than 192 bytes. The following responses have the noted effects:

• ERR. The full-speed transaction completed with a time-out or bad CRC and this is a reflection of that error to the host. The host controller sets the \( ERR \) bit in the \( siTD.Status \) field and sets the \( Active \) bit to a zero.

• Transaction Error (XactErr). The complete-split transaction encounters a Timeout, CRC16 failure, etc. The \( siTD.Status \) field \( XactErr \) field is set to a one and the complete-split transaction must be retried immediately. The host controller must use an internal error counter to count the number of retries as a counter field is not provided in the siTD data structure. The host controller will not retry more than two times. If the host controller exhausts the retries or the end of the micro-frame occurs, the \( Active \) bit is set to zero.

• DATAx (0 or 1). This response signals that the final data for the split transaction has arrived. The transfer state of the siTD is advanced and the \( Active \) bit is set to a zero. If the \( Bytes\ To\ Transfer \) field has not decremented to zero (including the reception of the data payload in the DATAx response), then less data than was expected, or allowed for was actually received. This short packet event does not set the USBINT status bit in the USBSTS register to a one. The host controller will not detect this condition.

• NYET (and Last). On each NYET response, the host controller also checks to determine whether this is the last complete-split for this split transaction. Last was defined in Section Periodic Isochronous - Do Complete Split. If it is the last complete-split (with a NYET response), then the transfer state of the siTD is not advanced (never received any data) and the \( Active \) bit is set to a zero. No bits are set in the \( Status \) field because this is essentially a skipped transaction. The transaction translator must have responded to all the scheduled clompete-splits with NYETs,
meaning that the start-split issued by the host controller was not received. This result should be interpreted by system software as if the transaction was completely skipped. The test for whether this is the last complete split can be performed by XORing C-mask with C-prog-mask. A zero result indicates that all complete-splits have been executed.

- **MDATA (and Last).** See above description for testing for Last. This can only occur when there is an error condition. Either there has been a babble condition on the full-speed link, which delayed the completion of the full-speed transaction, or software set up the $S$-mask and/or $C$-masks incorrectly. The host controller must set $XactErr$ bit to a one and the $Active$ bit is set to a zero.

- **NYET (and not Last).** See above description for testing for Last. The complete-split transaction received a NYET response from the transaction translator. Do not update any transfer state (except for $C$-prog-mask) and stay in this state.

- **MDATA (and not Last).** The transaction translator responds with an MDATA when it has partial data for the split transaction. For example, the full-speed transaction data payload spans from micro-frame X to X+1 and during micro-frame X, the transaction translator will respond with an MDATA and the data accumulated up to the end of micro-frame X. The host controller advances the transfer state to reflect the number of bytes received.

If Test A succeeds, but Test B fails, it means that one or more of the complete-splits have been skipped. The host controller sets the *Missed Micro-Frame* status bit and sets the $Active$ bit to a zero.

### 42.5.3.12.3.6 Complete-Split for Scheduling Boundary Cases 2a, 2b

Boundary cases 2a and 2b (INs only) (see Figure 42-24) require that the host controller use the transaction state context of the previous siTD to finish the split transaction. The table below enumerates the transaction state fields.

<table>
<thead>
<tr>
<th>Buffer State</th>
<th>Status</th>
<th>Execution Progress</th>
</tr>
</thead>
<tbody>
<tr>
<td>Total Bytes To Transfer</td>
<td>All bits in the status field</td>
<td>$C$-prog-mask</td>
</tr>
<tr>
<td>P (page select)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Current Offset</td>
<td></td>
<td></td>
</tr>
<tr>
<td>TP (transaction position)</td>
<td></td>
<td></td>
</tr>
<tr>
<td>T-count (transaction count)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**NOTE**

$TP$ and $T$-count are used only for Host to Device (OUT) endpoints.
If software has budgeted the schedule of this data stream with a frame wrap case, then it must initialize the siTD.Back Pointer field to reference a valid siTD and will have the siTD.Back Pointer.T-bit in the siTD.Back Pointer field set to a zero. Otherwise, software must set the siTD.Back Pointer.T-bit in the siTD.Back Pointer field to a one. The host controller's rules for interpreting when to use the siTD.Back Pointer field are listed below. These rules apply only when the siTD's Active bit is a one and the SplitXState is Do Complete Split.

- When cMicroFrameBit is a 1h and the siTDX.Back Pointer.T-bit is a zero, or
- If cMicroFrameBit is a 2h and siTDX.S-mask[0] is a zero

When either of these conditions apply, then the host controller must use the transaction state from siTDX-1.

In order to access siTDX-1, the host controller reads on-chip the siTD referenced from siTDX.Back Pointer.

The host controller must save the entire state from siTDX while processing siTDX-1. This is to accommodate for case 2b processing. The host controller must not recursively walk the list of siTD.Back Pointers.

If siTDX-1 is active (Active bit is a one and SplitXStat is Do Complete Split), then both Test A and Test B are applied as described above. If these criteria to execute a complete-split are met, the host controller executes the complete split and evaluates the results as described above. The transaction state (see Table 42-51) of siTDX-1 is appropriately advanced based on the results and written back to memory. If the resultant state of siTDX-1's Active bit is a one, then the host controller returns to the context of siTDX, and follows its next pointer to the next schedule item. No updates to siTDX are necessary.

If siTDX-1 is active (Active bit is a one and SplitXStat is Do Start Split), then the host controller must set Active bit to a zero and Missed Micro-Frame status bit to a one and the resultant status written back to memory.

If siTDX-1's Active bit is a zero, (because it was zero when the host controller first visited siTDX-1 via siTDX's back pointer, it transitioned to zero as a result of a detected error, or the results of siTDX-1's complete-split transaction transitioned it to zero), then the host controller returns to the context of siTDX and transitions its SplitXState to Do Start Split. The host controller then determines whether the case 2b start split boundary condition exists (that is, if cMicroframeBit is a 1b and siTDX.S-mask[0] is a 1b). If this criterion is met the host controller immediately executes a start-split transaction and appropriately advances the transaction state of siTDX, then follows siTDX.Next Pointer to the next schedule item. If the criterion is not met, the host controller simply follows siTDX.Next Pointer to the next schedule item. Note that in the case of a 2b boundary case, the split-transaction of siTDX-1 will have its Active bit set to zero when the host controller returns
to the context of $siTD_X$. Also, note that software should not initialize an siTD with $C$-mask bits 0 and 1 set to a one and an $S$-mask with bit zero set to a one. This scheduling combination is not supported and the behavior of the host controller is undefined.

### 42.5.3.12.3.7 Split Transaction for Isochronous - Processing Examples

There is an important difference between how the hardware/software manages the isochronous split transaction state machine and how it manages the asynchronous and interrupt split transaction state machines.

The asynchronous and interrupt split transaction state machines are encapsulated within a single queue head. The progress of the data stream depends on the progress of each split transaction. In some respects, the split-transaction state machine is sequenced via the Execute Transaction queue head traversal state machine (see Figure 42-17).

Isochronous is a pure time-oriented transaction/data stream. The interface data structures are optimized to efficiently describe transactions that need to occur at specific times. The isochronous split-transaction state machine must be managed across these time-oriented data structures. This means that system software must correctly describe the scheduling of split-transactions across more than one data structure.

Then the host controller must make the appropriate state transitions at the appropriate times, in the correct data structures.

For example, the table below illustrates a couple of frames worth of scheduling required to schedule a case 2a full-speed isochronous data stream.

<table>
<thead>
<tr>
<th>siTDX Micro-Frames</th>
<th>Initial SplitXState</th>
</tr>

<td>C-Mask</td>
</tr>
</tbody>
</table>

Table 42-52. Example Case 2a - Software Scheduling siTDs for an IN Endpoint
This example shows the first three siTDs for the transaction stream. Because this is the case-2a frame-wrap case, \textit{S-masks} of all siTDs for this endpoint have a value of 10h (a one bit in micro-frame 4) and \textit{C-mask} value of C3h (one-bits in micro-frames 0, 1, 6 and 7). Additionally, sofware ensures that the \textit{Back Pointer} field of each siTD references the appropriate siTD data structure (and the \textit{Back PointerT-bits} are set to zero).

The initial \textit{SplitXState} of the first siTD is Do Start Split. The host controller will visit the first siTD eight times during frame X. The C-mask bits in micro-frames 0 and 1 are ignored because the state is Do Start Split. During micro-frame 4, the host controller determines that it can run a start-split (and does) and changes \textit{SplitXState} to Do Complete Split. During micro-frames 6 and 7, the host controller executes complete-splits. Notice the siTD for frame X+1 has its \textit{SplitXState} initialized to Do Complete Split. As the host controller continues to traverse the schedule during \textit{H-Frame} X+1, it will visit the second siTD eight times. During micro-frames 0 and 1 it will detect that it must execute complete-splits.

During \textit{H-Frame} X+1, micro-frame 0, the host controller detects that siTD\textsubscript{X+1}'s \textit{Back Pointer}.\textit{T-bit} is a zero, saves the state of siTD\textsubscript{X+1} and fetches siTD\textsubscript{X}. It executes the complete split transaction using the transaction state of siTD\textsubscript{X}. If the siTD\textsubscript{X} split transaction is complete, siTD's \textit{Active} bit is set to zero and results written back to siTD\textsubscript{X}. The host controller retains the fact that siTD\textsubscript{X} is retired and transitions the \textit{SplitXState} in the siTD\textsubscript{X+1} to Do Start Split. At this point, the host controller is prepared to execute the start-split for siTD\textsubscript{X+1} when it reaches micro-frame 4. If the split-transaction completes early (transaction-complete is defined in Section \textit{Periodic Isochronous - Do Complete Split}), that is, before all the scheduled complete-splits have been executed, the host controller will transition \textit{siTD\textsubscript{X}.SplitXState} to Do Start Split early and naturally skip the remaining scheduled complete-split transactions. For this example, \textit{siTD\textsubscript{X+1}} does not receive a DATA0 response until \textit{H-Frame} X+2, micro-frame 1.

During \textit{H-Frame} X+2, micro-frame 0, the host controller detects that siTD\textsubscript{X+2}'s \textit{Back Pointer}.\textit{T-bit} is a zero, saves the state of siTD\textsubscript{X+2} and fetches siTD\textsubscript{X+1}. As described above, it executes another split transaction, receives an MDATA response, updates the transfer state, but does not modify the \textit{Active} bit. The host controller returns to the context of siTD\textsubscript{X+2}, and traverses its next pointer without any state change updates to siTD\textsubscript{X+2}. S

During \textit{H-Frame} X+2, micro-frame 1, the host controller detects siTD\textsubscript{X+2}'s \textit{S-mask}[0] is a zero, saves the state of siTD\textsubscript{X+2} and fetches siTD\textsubscript{X+1}. It executes another complete-split transaction, receives a DATA0 response, updates the transfer state and sets the \textit{Active} bit to a zero. It returns to the state of siTD\textsubscript{X+2} and changes its \textit{SplitXState} to Do Start Split. At this point, the host controller is prepared to execute start-splits for siTD\textsubscript{X+2} when it reaches micro-frame 4.
42.5.3.13 Host Controller Pause

When the host controller's *HCHalted* bit in the USBSTS register is a zero, the host controller is sending SOF (Start OF Frame) packets down all enabled ports.

When the schedules are enabled, the EHCI host controller will access the schedules in main memory each micro-frame. This constant pinging of main memory is known to create Arm platform power management problems for mobile systems. Specifically, mobile systems aggressively manage the state of the Arm platform, based on recent history usage. In the more aggressive power saving modes, the Arm platform can disable its caches. Current PC architectures assume that bus-master accesses to main memory must be cache-coherent. So, when bus masters are busy touching memory, the Arm platform power management software can detect this activity over time and inhibit the transition of the Arm platform into its lowest power savings mode. USB controllers are bus-masters and the frequency at which they access their memory-based schedules keeps the Arm platform power management software from placing the Arm platform into its lowest power savings state.

USB Host controllers don't access main memory when they are suspended. However, there are a variety of reasons why placing the USB controllers into suspend won't work, but they are beyond the scope of this document. The base requirement is that the USB controller needs to be kept out of main memory, while at the same time, the USB bus is kept from going into suspend.

EHCI controllers provide a large-grained mechanism that can be manipulated by system software to change the memory access pattern of the host controller. System software can manipulate the schedule enable bits in the USBCMD register to turn on/off the scheduling traversal. A software heuristic can be applied to implement an on/off duty cycle that allows the USB to make reasonable progress and allow the Arm platform power management to get the Arm platform into its lowest power state. This method is not intended to be applied at all times to throttle USB, but should only be applied in very specific configurations and usage loads. For example, when only a keyboard or mouse is attached to the USB, the heuristic could detect times when the USB is attempting to move data only very infrequently and can adjust the duty cycle to allow the Arm platform to reach its low power state for longer periods of time. Similarly, it could detect increases in the USB load and adjust the duty cycle appropriately, even to the point where the schedules are never disabled. The assumption here is that the USB is moving data and the Arm platform will be required to process the data streams.
It is suggested that in order to provide a complete solution for the system, the companion host controllers should also provide a similar method to allow system software to inhibit the companion host controller from accessing its shared memory based data structures (schedule lists or otherwise).

### 42.5.3.14 Port Test Modes -Host Operational Model

EHCI host controllers must implement the port test modes Test J_State, Test K_State, Test_Packet, Test Force_Enable, and Test SE0_NAK as described in the USB Specification Revision 2.0.

The system is only allowed to test ports that are owned by the EHCI controller (for example, CF-bit is a one and PortOwner bit is a zero). System software is allowed to have at most one port in test mode at a time. Placing more than one port in test mode will yield undefined results. The required, per port test sequence is (assuming the CF-bit in the USB_n_CONFIGFLAG register is a one):

- Disable the periodic and asynchronous schedules by setting the Asynchronous Schedule Enable and Periodic Schedule Enable bits in the USBCMD register to a zero.
- Place all enabled root ports into the suspended state by setting the Suspend bit in each appropriate USB_n_PORTSC register to a one.
- Set the Run/Stop bit in the USBCMD register to a zero and wait for the HCHalted bit in the USBSTS register, to transition to a one. Note that an EHCI host controller implementation may optionally allow port testing with the Run/Stop bit set to a one. However, all host controllers must support port testing with Run/Stop set to a zero and HCHalted set to a one.
- Set the Port Test Control field in the port under test PORTSC register to the value corresponding to the desired test mode. If the selected test is Test_Force_Enable, then the Run/Stop bit in the USBCMD register must then be transitioned back to one, in order to enable transmission of SOFs out of the port under test.
- When the test is complete, system software must ensure the host controller is halted (HCHalted bit is a one) then it terminates and exits test mode by setting HCRest to a one.

### 42.5.3.15 Interrupts-Host Operational Model

The EHCI Host Controller hardware provides interrupt capability based on a number of sources.

There are several general groups of interrupt sources:
interrupts as a result of executing transactions from the schedule (success and error conditions),
• Host controller events (Port change events, etc.), and
• Host Controller error events

All transaction-based sources are maskable through the Host Controller's Interrupt Enable register (USBINTR, see Section Interrupt Enable Register (USB_nUSBINTR)). Additionally, individual transfer descriptors can be marked to generate an interrupt on completion. This section describes each interrupt source and the processing that occurs in response to the interrupt.

During normal operation, interrupts may be immediate or deferred until the next interrupt threshold occurs. The interrupt threshold is a tunable parameter via the Interrupt Threshold Control field in the USBCMD register. The value of this register controls when the host controller will generate an interrupt on behalf of normal transaction execution. When a transaction completes during an interrupt interval period, the interrupt signaling the completion of the transfer will not occur until the interrupt threshold occurs. For example, the default value is eight micro-frames. This means that the host controller will not generate interrupts any more frequently than once every eight micro-frames.

Section Host System Error details effects of a host system error.

If an interrupt has been scheduled to be generated for the current interrupt threshold interval, the interrupt is not signaled until after the status for the last complete transaction in the interval has been written back to host memory. This may sometimes result in the interrupt not being signaled until the next interrupt threshold.

Initial interrupt processing is the same, regardless of the reason for the interrupt. When an interrupt is signaled by the hardware, Arm platform control is transferred to host controller's USB interrupt handler. The precise mechanism to accomplish the transfer is OS specific. For this discussion it is just assumed that control is received. When the interrupt handler receives control, its first action is to read the USBSTS (USB Status Register). It then acknowledges the interrupt by clearing all of the interrupt status bits by writing ones to these bit positions. The handler then determines whether the interrupt is due to schedule processing or some other event. After acknowledging the interrupt, the handler (via an OS-specific mechanism), schedules a deferred procedure call (DPC) which will execute later. The DPC routine processes the results of the schedule execution. The precise mechanisms used are beyond the scope of this document.

Note: the host controller is not required to de-assert a currently active interrupt condition when software sets the interrupt enables (in the USBINR register, see Section Interrupt Enable Register (USB_nUSBINTR)) to a zero. The only reliable method software should use for acknowledging an interrupt is by transitioning the appropriate status bits in the USBSTS register (Section USB Status Register (USB_nUSBSTS)) from a one to a zero.
42.5.3.15.1 Transfer/Transaction Based Interrupts

These interrupt sources are associated with transfer and transaction progress. They are all dependent on the next interrupt threshold.

42.5.3.15.1.1 Transaction Error

A transaction error is any error that caused the host controller to think that the transfer did not complete successfully.

The table below lists the events/responses that the host can observe as a result of a transaction. The effects of the error counter and interrupt status are summarized in the following paragraphs. Most of these errors set the XactErr status bit in the appropriate interface data structure.

There is a small set of protocol errors that relate only when executing a queue head and fit under the umbrella of a WRONG PID error that are significant to explicitly identify. When these errors occur, the XactErr status bit in the queue head is set and the CErr field is decremented. When the PIDCode indicates a SETUP, the following responses are protocol errors and result in XactErr bit being set to a one and the CErr field being decremented.

- EPS field indicates a high-speed device and it returns a Nak handshake to a SETUP.
- EPS field indicates a high-speed device and it returns a Nyet handshake to a SETUP.
- EPS field indicates a low- or full-speed device and the complete-split receives a Nak handshake.

</table>

1. If occurs in a queue head, then USBERRINT is asserted only when CErr counts down from a one to a zero. In addition the queue is halted, see Halting a Queue Head.
2. The host controller received a response from the device, but it could not recognize the PID as a valid PID.
42.5.3.15.1.2 Serial Bus Babble

When a device transmits more data on the USB than the host controller is expecting for this transaction, it is defined to be babbling. In general, this is called a *Packet Babble*.

When a device sends more data than the *Maximum Length* number of bytes, the host controller sets the *Babble Detected* bit to a one and halts the endpoint if it is using a queue head (see [Halting a Queue Head](https://example.com)). *Maximum Length* is defined as the minimum of *Total Bytes to Transfer* and *Maximum Packet Size*. The *CErr* field is not decremented for a packet babble condition (only applies to queue heads). A babble condition also exists if IN transaction is in progress at High-speed EOF2 point. This is called a frame babble. A frame babble condition is recorded into the appropriate schedule data structure. In addition, the host controller must disable the port to which the frame babble is detected.

The *USBERRINT* bit in the USB_n_USBSTS register is set to a one and if the *USB Error Interrupt Enable* bit in the USB_n_USBINTR register is a one, then a hardware interrupt is signaled to the system at the next interrupt threshold. The host controller must never start an OUT transaction that will babble across a micro-frame EOF.

**NOTE**

When a host controller detects a data PID mismatch, it must either: disable the packet babble checking for the duration of the bus transaction or do packet babble checking based solely on *Maximum Packet Size*. The USB core specification defines the requirements on a data receiver when it receives a data PID mismatch (for example, expects a DATA0 and gets a DATA1 or visa-versa). In summary, it must ignore the received data and respond with an ACK handshake, in order to advance the transmitter's data sequence.

The EHCI interface allows System software to provide buffers for a Control, Bulk or Interrupt IN endpoint that are not an even multiple of the maximum packet size specified by the device. Whenever a device misses an ACK for an IN endpoint, the host and device are out of synchronization with respect to the progress of the data transfer. The host controller may have advanced the transfer to a buffer that is less than maximum packet size. The device will re-send its maximum packet size data packet, with the original data PID, in response to the next IN token. In order to properly manage the bus protocol, the host controller must disable the packet babble check when it observes the data PID mismatch.
42.5.3.15.1.3  Data Buffer Error

This event indicates that an overrun of incoming data or a underrun of outgoing data has occurred for this transaction.

This would generally be caused by the host controller not being able to access required data buffers in memory within necessary latency requirements. These conditions are not considered transaction errors, and do not effect the error count in the queue head. When these errors do occur, the host controller records the fact the error occurred by setting the Data Buffer Error bit in the queue head, iTD or siTD.

If the data buffer error occurs on a non-isochronous IN, the host controller will not issue a handshake to the endpoint. This will force the endpoint to resend the same data (and data toggle) in response to the next IN to the endpoint.

If the data buffer error occurs on an OUT, the host controller must corrupt the end of the packet so that it cannot be interpreted by the device as a good data packet. Simply truncating the packet is not considered acceptable. An acceptable implementation option is to 1's complement the CRC bytes and send them. There are other options suggested in the Transaction Translator section of the USB Specification Revision 2.0.

42.5.3.15.1.4  USB Interrupt (Interrupt on Completion (IOC))

Transfer Descriptors (iTDs, siTDs, and queue heads (qTDs)) contain a bit that can be set to cause an interrupt on their completion. The completion of the transfer associated with that schedule item causes the USB Interrupt (USBINT) bit in the USB_n_USBSTS register to be set to a one.

In addition, if a short packet is encountered on an IN transaction associated with a queue head, then this event also causes USBINT to be set to a one. If the USB Interrupt Enable bit in the USB_n_USBINTR register is set to a one, a hardware interrupt is signaled to the system at the next interrupt threshold. If the completion is because of errors, the USBERRINT bit in the USB_n_USBSTS register is also set to a one.

42.5.3.15.1.5  Short Packet

Reception of a data packet that is less than the endpoint's Max Packet size during Control, Bulk or Interrupt transfers signals the completion of the transfer. Whenever a short packet completion occurs during a queue head execution, the USBINT bit in the USB_n_USBSTS register is set to a one.

If the USB Interrupt Enable bit is set in the USB_n_USBINTR register, a hardware interrupt is signaled to the system at the next interrupt threshold.
42.5.3.15.2 Host Controller Event Interrupts

These interrupt sources are independent of the interrupt threshold (with the one exception being the Interrupt on Async Advance, see Section Interrupt on Async Advance).

42.5.3.15.2.1 Port Change Events

Port registers contain status and status change bits. When the status change bits are set to a one, the host controller sets the Port Change Detect bit in the USBSTS register to a one.

If the Port Change Interrupt Enable bit in the USB_n_USBINTR register is a one, then the host controller will issue a hardware interrupt. The port status change bits include:

- Connect Status Change
- Port Enable/Disable Change
- Over-current Change
- Force Port Resume

42.5.3.15.2.2 Frame List Rollover

This event indicates that the host controller has wrapped the frame list. The current programmed size of the frame list effects how often this interrupt occurs.

If the frame list size is 1024, then the interrupt will occur every 1024 milliseconds, if it is 512, then it will occur every 512 milliseconds, etc. When a frame list rollover is detected, the host controller sets the Frame List Rollover bit in the USB.USBSTS register to a one. If the Frame List Rollover Enable bit in the USB.USBINTR register is set to a one, the host controller issues a hardware interrupt. This interrupt is not delayed to the next interrupt threshold.

42.5.3.15.2.3 Interrupt on Async Advance

This event is used for deterministic removal of queue heads from the asynchronous schedule. Whenever the host controller advances the on-chip context of the asynchronous schedule, it evaluates the value of the Interrupt on Async Advance Doorbell bit in the USB.USBCMD register.

If it is a one, it sets the Interrupt on Async Advance bit in the USB.USBSTS register to a one. If the Interrupt on Async Advance Enable bit in the USB.USBINTR register is a one, the host controller issues a hardware interrupt at the next interrupt threshold. A detailed explanation of this feature is described in Section Removing Queue Heads from Asynchronous Schedule.
42.5.3.15.2.4 Host System Error

The host controller is a bus master and any interaction between the host controller and the system may experience errors.

The type of host error may be catastrophic to the host controller (such as a Master Abort) making it impossible for the host controller to continue in a coherent fashion. In the presence of non-catastrophic host errors, such as parity errors, the host controller could potentially continue operation. The recommended behavior for these types of errors is to escalate it to a catastrophic error and halt the host controller. Host-based error must result in the following actions:

- The Run/Stop bit in the USB.USBCMD register is set to a zero.
- The following bits in the USB.USBSTS register are set:
  - Host System Error bit is to a one.
  - HCHalted bit is set to a one.
- If the Host System Error Enable bit in the USB.USBINTR register is a one, then the host controller will issue a hardware interrupt. This interrupt is not delayed to the next interrupt threshold. The following table summarizes the required actions taken on the various host errors.

<table>
<thead>
<tr>
<th>Cycle Type</th>
<th>Master Abort</th>
<th>Target Abort</th>
<th>Data Phase Parity</th>
</tr>
</thead>
<tbody>
<tr>
<td>Frame list pointer fetch (read)</td>
<td>Fatal</td>
<td>Fatal</td>
<td>Fatal [o]</td>
</tr>
<tr>
<td>siTD fetch (read)</td>
<td>Fatal</td>
<td>Fatal</td>
<td>Fatal [o]</td>
</tr>
<tr>
<td>siTD status write-back (write)</td>
<td>Fatal [o]</td>
<td>Fatal [o]</td>
<td>Fatal [o]</td>
</tr>
<tr>
<td>iTD fetch (read)</td>
<td>Fatal</td>
<td>Fatal</td>
<td>Fatal [o]</td>
</tr>
<tr>
<td>iTD status write-back (write)</td>
<td>Fatal [o]</td>
<td>Fatal [o]</td>
<td>Fatal [o]</td>
</tr>
<tr>
<td>qTD fetch (read)</td>
<td>Fatal</td>
<td>Fatal</td>
<td>Fatal [o]</td>
</tr>
<tr>
<td>qHD status write-back (write)</td>
<td>Fatal [o]</td>
<td>Fatal [o]</td>
<td>Fatal [o]</td>
</tr>
<tr>
<td>Data write</td>
<td>Fatal [o]</td>
<td>Fatal [o]</td>
<td>Fatal [o]</td>
</tr>
<tr>
<td>Data read</td>
<td>Fatal</td>
<td>Fatal</td>
<td>Fatal [o]</td>
</tr>
</tbody>
</table>

Potentially, a host controller implementation could continue operation without a halt. However, the recommended behavior is to halt the host controller.

**NOTE**

After a Host System Error, Software must reset the host controller through HCReset in the USB.USBCMD register before re-initializing and restarting the host controller.
42.5.4 EHCI Deviation

For the purposes a dual-role Host/Device controller with support for On-The-Go applications, it is necessary to deviate from the EHCI specification. Enhanced Host Controller Interface Specification for Universal Serial Bus, Revision 0.95, November 2000, Intel Corporation. http://www.intel.com. Device operation & On-The-Go operation is not specified in the EHCI and thus the implementation supported in this core is proprietary.

The host mode operation of the core is near EHCI compatible with few minor differences documented in this section.

The particulars of the deviations occur in the areas summarized here:

- Embedded Transaction Translator - Allows direct attachment of FS and LS devices in host mode without the need for a companion controller.
- Device operation - In host mode the device operational registers are generally disabled and thus device mode is mostly transparent when in host mode. However, there are a couple exceptions documented in the following sections.
- Embedded design interface - This core does not have a PCI Interface and therefore the PCI configuration registers described in the EHCI specification are not applicable.
- On-The-Go Operation - This design includes an On-The-Go controller for Port #1.

42.5.4.1 Embedded Transaction Translator Function

The OTG controller supports directly connected full and low speed devices without requiring a companion controller by including the capabilities of a USB 2.0 high speed hub transaction translator.

Although there is no separate Transaction Translator block in the system, the transaction translator function normally associated with a high speed hub has been implemented within the DMA and Protocol engine blocks. The embedded transaction translator function is an extension to EHCI interface, but makes use of the standard data structures and operational models that exist in the EHCI specification to support full and low speed devices.

42.5.4.1.1 Capability Registers

The following additions have been added to the capability registers to support the embedded Transaction Translator Function:
42.5.4.1.2 Operational Registers

The following additions have been added to the operational registers to support the embedded TT:

- Addition of two-bit Port Speed (PSPD) to the Port Status & Control (USB_portSC1) register.

42.5.4.1.3 Discovery-EHCI Deviation

In a standard EHCI controller design, the EHCI host controller driver detects a Full speed (FS) or Low speed (LS) device by noting if the port enable bit is set after the port reset operation.

The port enable will only be set in a standard EHCI controller implementation after the port reset operation and when the host and device negotiate a High-Speed connection (that is, Chirp completes successfully).

Because this controller has an embedded Transaction Translator, the port enable will always be set after the port reset operation regardless of the result of the host device chirp result and the resulting port speed will be indicated by the PSPD field in USB.PORTSCx.

Therefore, the standard EHCI host controller driver requires an alteration to handle directly connected Full and Low speed devices or hubs.

The change is a fundamental one in that is summarized in the following table.

<table>
<thead>
<tr>
<th>Standard EHCI</th>
<th>EHCI with embedded Transaction Translator</th>
</tr>
</thead>
<tbody>
<tr>
<td>After port enable bit is set following a connection and reset sequence, the device/hub is assumed to be HS.</td>
<td>After port enable bit is set following a connection and reset sequence, the device/hub speed is noted from USB.PORTSCx.</td>
</tr>
<tr>
<td>FS and LS devices are assumed to be downstream from a HS hub thus, all port-level control is performed through the Hub Class to the nearest Hub.</td>
<td>FS and LS device can be either downstream from a HS hub or directly attached. When the FS/LS device is downstream from a HS hub, then port-level control is done using the Hub Class through the nearest Hub. When a FS/LS device is directly attached, then port-level control is accomplished using USB.PORTSCx.</td>
</tr>
<tr>
<td>FS and LS devices are assumed to be downstream from a HS hub with HubAddr=X, [where HubAddr &gt; 0 and HubAddr is the address of the Hub where the bus transitions from HS to FS/LS (ie. Split target hub)]</td>
<td>FS and LS device can be either downstream from a HS hub with HubAddr = X [HubAddr &gt; 0] or directly attached [where HubAddr = 0 and HubAddr is the address of the Root Hub where the bus transitions from HS to FS/LS (ie. Split target hub is the root hub)]</td>
</tr>
</tbody>
</table>
42.5.4.1.4 Data Structures

The same data structures used for FS/LS transactions though a HS hub are also used for transactions through the Root Hub with sm embedded Transaction Translator.

Here it is demonstrated how the Hub Address and Endpoint Speed fields should be set for directly attached FS/LS devices and hubs:

1. QH (for direct attach FS/LS) - Async. (Bulk/Control Endpoints) Periodic (Interrupt)
   • Hub Address = 0
   • Transactions to direct attached device/hub.
     • QH.EPS = Port Speed
   • Transactions to a device downstream from direct attached FS hub.
     • QH.EPS = Downstream Device Speed

   **NOTE**
   When QH.EPS = 01 (LS) and PORTSCx.PSPD = 00 (FS), a LS-pre-pid will be sent before the transmitting LS traffic.
   
   Maximum Packet Size must be less than or equal 64 or undefined behaviour may result.

2. siTD (for direct attach FS) - Periodic (ISO Endpoint)
   • All FS ISO transactions:
     • Hub Address = 0
     • siTD.EPS = 00 (full speed)
     • Maximum Packet Size must less than or equal to 1023 or undefined behaviour may result.

42.5.4.1.5 Operational Model

The operational models are well defined for the behavior of the Transaction Translator (see USB 2.0 specification, Universal Serial Bus Specification, Revision 2.0, April 2000, Compaq, Hewlett-Packard, Intel, Lucent, Microsoft, NEC, Philips. http://www.usb.org) and for the EHCI controller moving packets between system memory and a USB-HS hub. Because the embedded Transaction Translator exists within the host controller there is no physical bus between EHCI host controller driver and the USB FS/LS bus. These sections will briefly discuss the operational model for how the EHCI and Transaction Translator operational models are combined without the physical bus between. The following sections assume the reader is familiar with both the EHCI and USB 2.0 Transaction Translator operational models.
42.5.4.1.5.1 Micro-frame Pipeline

The EHCI operational model uses the concept of H-frames and B-frames to describe the pipeline between the Host (H) and the Bus (B). The embedded Transaction Translator shall use the same pipeline algorithms specified in the USB 2.0 specification for a Hub-based Transaction Translator.

All periodic transfers always begin at B-frame 0 (after SOF) and continue until the stored periodic transfers are complete. As an example of the micro-frame pipeline implemented in the embedded Transaction Translator, all periodic transfers that are tagged in EHCI to execute in H-frame 0 will be ready to execute on the bus in B-frame 0.

It is important to note that when programming the S-mask and C-masks in the EHCI data structures to schedule periodic transfers for the embedded Transaction Translator, the EHCI host controller driver must follow the same rules specified in EHCI for programming the S-mask and C-mask for downstream Hub-based Transaction Translators.

Once periodic transfers are exhausted, any stored asynchronous transfer will be moved. Asynchronous transfers are opportunistic in that they shall execute whenever possible and their operation is not tied to H-frame and B-frame boundaries with the exception that an asynchronous transfer can not babble through the SOF (start of B-frame 0.)

42.5.4.1.5.2 Split State Machines

The start and complete split operational model differs from EHCI slightly because there is no bus medium between the EHCI controller and the embedded Transaction Translator.

Where a start or complete-split operation would occur by requesting the split to the HS hub, the start/complete split operation is simple an internal operation to the embedded Transaction Translator. The following table summarizes the conditions where handshakes are emulated from internal state instead of actual handshakes to HS split bus traffic.

<table>
<thead>
<tr>
<th>Condition</th>
<th>Emulate TT Response</th>
</tr>
</thead>
<tbody>
<tr>
<td>Start-Split: All asynchronous buffers full.</td>
<td>NAK</td>
</tr>
<tr>
<td>Start-Split: All periodic buffers full.</td>
<td>ERR</td>
</tr>
<tr>
<td>Start-Split: Success for start of Async. Transaction.</td>
<td>ACK</td>
</tr>
<tr>
<td>Start-Split: Start Periodic Transaction.</td>
<td>No Handshake (Ok)</td>
</tr>
<tr>
<td>Complete-Split: Failed to find transaction in queue.</td>
<td>Bus Time Out</td>
</tr>
<tr>
<td>Complete-Split: Transaction in Queue is Busy.</td>
<td>NYET</td>
</tr>
<tr>
<td>Complete-Split: Transaction in Queue is Complete.</td>
<td>[Actual Handshake from LS/FS device]</td>
</tr>
</tbody>
</table>

### 42.5.4.1.5.3 Asynchronous Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.
- Transaction tracking for 2 data pipes.

#### 42.5.4.1.5.3.1 USB 2.0 - 11.17.3

- Sequencing is provided & a packet length estimator ensures no full-speed/low-speed packet babbles into SOF time.

#### 42.5.4.1.5.3.2 USB 2.0 - 11.17.4

- Transaction tracking for 2 data pipes.

### 42.5.4.1.5.4 Periodic Transaction Scheduling and Buffer Management

The following USB 2.0 specification items are implemented in the embedded Transaction Translator:

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
  - EOF
  - Idle for more than 4 micro-frames
- Transaction tracking for up to 16 data pipes.
- Complete-split transaction searching.

**NOTE**

There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

#### 42.5.4.1.5.4.1 USB 2.0 - 11.18.6.[1-2]

- Abort of pending start-splits
  - EOF (and not started in micro-frames 6)
  - Idle for more than 4 micro-frames
- Abort of pending complete-splits
• EOF
• Idle for more than 4 micro-frames

42.5.4.1.5.4.2 USB 2.0 - 11.18.[7-8]
• Transaction tracking for up to 16 data pipes.
• Complete-split transaction searching.

**NOTE**
There is no data schedule mechanism for these transactions other than the micro-frame pipeline. The embedded TT assumes the number of packets scheduled in a frame does not exceed the frame duration (1 ms) or else undefined behavior may result.

42.5.4.1.5.5 Multiple Transaction Translators

The maximum number of embedded Transaction Translators that is currently supported is one as indicated by the N_TT field in the Host Controller Structural Parameters (USB_nHCSPARAMS) register.

42.5.4.2 Device Operation

The co-existence of a device operational controller within the host controller has little effect on EHCI compatibility for host operation except as noted in this section.

42.5.4.2.1 USB_USBMODE Register

Given that the dual-role controller is initialized in neither host nor device mode, the USB Device Mode (USB_nUSBMODE) register must be programmed for host operation before the EHCI host controller driver can begin EHCI host operations.

42.5.4.2.2 Non-Zero Fields the Register File

Some of the reserved fields and reserved addresses in the capability registers and operational register have use in device mode, the following must be adhered to:

• Write operations to all EHCI reserved fields (some of which are device fields) with the operation registers should always be written to zero. This is an EHCI requirement of the device controller driver that must be adhered to.
• Read operations by the host controller must properly mask EHCI reserved fields (some of which are device fields) because fields that are used exclusive for device are undefined in host mode.
42.5.4.2.3  **SOF Interrupt**

This SOF Interrupt used for device mode is shared as a free running 125us interrupt for host mode.

EHCI does not specify this interrupt but it has been added for convenience and as a potential software time base. See USB Status Register (USB\_nUSBSTS) and Interrupt Enable Register (USB\_nUSBINTR) registers.

42.5.4.3  **Embedded Design Interface**

This is an Embedded USB Host Controller as defined by the EHCI specification and thus does not implement the PCI configuration registers.

42.5.4.3.1  **Frame Adjust Register**

Given that the optional PCI configuration registers are not included in this implementation, there is no corresponding bit level timing adjustments like is provided by the Frame Adjust register in the PCI configuration registers. Starts of micro-frames are timed precisely to 125 us using the transceiver clock as a reference clock. That is, a 60 Mhz transceiver clock for 8-bit physical interfaces & full-speed serial interfaces or 30 Mhz transceiver clock for 16-bit physical interfaces.

42.5.4.4  **Miscellaneous variations from EHCI**

42.5.4.4.1  **Programmable Physical Interface Behaviour**

This design supports multiple Physical interfaces which can operate in differing modes when the core is configured with software programmable Physical Interface Modes. Software programmability allows the selection of the Physical interface part during the board design phase instead of during the chip design phase. The control bits for selecting the Physical Interface operating mode have been added to the Port Status & Control (USB\_nPORTSC1) register providing a capability that is not defined by EHCI.

42.5.4.4.2  **Discovery**
42.5.4.4.2.1 Port Reset

The port connect methods specified by EHCI require setting the port reset bit in the Port Status & Control (USB_nPORTSC1) register for a duration of 10ms. Due to the complexity required to support the attachment of devices that are not high speed there are counter already present in the design that can count the 10ms reset pulse to alleviate the requirement of the software to measure this duration. Therefore, the basic connection is then summarized as the following:

• [Port Change Interrupt] Port connect change occurs to notify the host controller driver that a device has attached.
• Software shall write a '1' to reset the device.
• Software shall write a '0' to reset the device after 10 ms.
  • This step, which is necessary in a standard EHCI design, may be omitted with this implementation. Should the EHCI host controller driver attempt to write a '0' to the reset bit while a reset is in progress, the write will simple be ignored and the reset will continue until completion.
• [Port Change Interrupt] Port enable change occurs to notify the host controller that the device in now operational and at this point the port speed has been determined.

42.5.4.4.2.2 Port Speed Detection

After the port change interrupt indicates that a port is enabled, the EHCI stack should determine the port speed. Unlike the EHCI implementation, which will re-assign the port owner for any device that does not connect at High-Speed, this host controller supports direct attach of non High-Speed devices.

Therefore, the following differences are important regarding port speed detection:

• Port Owner is read-only and always reads 0.
• A 2-bit Port Speed indicator has been added to PORTSC to provide the current operating speed of the port to the host controller driver.
• A 1-bit High Speed indicator has been added to PORTSC to signify that the port is in High-Speed vs. Full/Low Speed - This information is redundant with the 2-bit Port Speed indicator above.

42.5.4.4.3 Port Test Mode

Port Test Control mode behaves fully as described in EHCI. An alternate host controller driver procedure is not necessary or supported.
42.5.5 Device Data Structures

This section defines the interface data structures used to communicate control, status, and data between Device Controller Driver (DCD) Software and the Device Controller.

The data structure definitions in this chapter support a 32-bit memory buffer address space. The interface consists of device Queue Heads and Transfer Descriptors.

**NOTE**
Software must ensure that no interface data structure reachable by the Device Controller spans a 4K-page boundary.

The data structures defined in the chapter are (from the device controller's perspective) a mix of read-only and read/writable fields. The device controller must preserve the read-only fields on all data structure writes.

The figure below shows the organization of the EndPoint Queue Head.

![Figure 42-27. EndPoint Queue Head Organization](image)

Endpoint queue heads are arranged in an array in a continuous area of memory pointed to by the USB.ENDPOINTLISTADDR pointer. The even-numbered device queue heads in the list support receive endpoints (OUT/SETUP) and the odd-numbered queue heads in the list are used for transmit endpoints (IN/INTERRUPT). The device controller will index into this array based upon the endpoint number received from the USB bus. All information necessary to respond to transactions for all primed transfers is contained in this list so the Device Controller can readily respond to incoming requests without having to traverse a linked list.
## NOTE
The Endpoint Queue Head List must be aligned to a 2k boundary.

### 42.5.5.1 Endpoint Queue Head (dQH)

The device Endpoint Queue Head (dQH) is where all transfers for a given endpoint are managed. The dQH is a 48-byte data structure, but must be aligned on 64-byte boundaries.

During priming of an endpoint, the dTD (device transfer descriptor) is copied into the overlay area of the dQH, which starts at the nextTD pointer DWord and continues through the end of the buffer pointers DWords. After a transfer is complete, the dTD status DWord is updated in the dTD pointed to by the currentTD pointer. While a packet is in progress, the overlay area of the dQH is used as a staging area for the dTD so that the Device Controller can access needed information with little minimal latency.

#### Table 42-57. Endpoint Queue Head (dQH)

| Bit 31 | Bit 30 | Bit 29 | Bit 28 | Bit 27 | Bit 26 | Bit 25 | Bit 24 | Bit 23 | Bit 22 | Bit 21 | Bit 20 | Bit 19 | Bit 18 | Bit 17 | Bit 16 | Bit 15 | Bit 14 | Bit 13 | Bit 12 | Bit 11 | Bit 10 | Bit 9 | Bit 8 | Bit 7 | Bit 6 | Bit 5 | Bit 4 | Bit 3 | Bit 2 | Bit 1 | Bit 0 |

</tbody>
</table>

42.5.5.1.2 Transfer Overlay-Endpoint Queue Head

The seven DWords in the overlay area represent a transaction working space for the device controller.

The general operational model is that the device controller can detect whether the overlay area contains a description of an active transfer. If it does not contain an active transfer, then it will not read the associated endpoint.

After an endpoint is readied, the dTD will be copied into this queue head overlay area by the device controller. Until a transfer is expired, software must not write the queue head overlay area or the associated transfer descriptor. When the transfer is complete, the device controller will write the results back to the original transfer descriptor and advance the queue.
See dTD for a description of the overlay fields.

### 42.5.5.1.3 Current dTD Pointer

The current dTD pointer is used by the device controller to locate the transfer in progress. This word is for Device Controller (hardware) use only and should not be modified by DCD software.

The following table describes the dTD Pointer.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-5</td>
<td>Current dTD. This field is a pointer to the dTD that is represented in the transfer overlay area. This field will be modified by the Device Controller to next dTD pointer during endpoint priming or queue advance.</td>
</tr>
<tr>
<td>4-0</td>
<td>Reserved. Bit reserved for future use and should be set to zero.</td>
</tr>
</tbody>
</table>

### 42.5.5.1.4 Set-up Buffer

The set-up buffer is dedicated storage for the 8-byte data that follows a set-up PID.

**NOTE**

Each endpoint has a TX and an RX dQH associated with it, and only the RX queue head is used for receiving setup data packets.

The following table describes the Multiple Mode Control.

<table>
<thead>
<tr>
<th>DWord</th>
<th>Bits</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>31-0</td>
<td>Setup Buffer 0. This buffer contains bytes 3 to 0 of an incoming setup buffer packet and is written by the device controller to be read by software.</td>
</tr>
<tr>
<td>2</td>
<td>31-0</td>
<td>Setup Buffer 1. This buffer contains bytes 7 to 4 of an incoming setup buffer packet and is written by the device controller to be read by software.</td>
</tr>
</tbody>
</table>

### 42.5.5.2 Endpoint Transfer Descriptor (dTD)

The dTD describes to the device controller the location and quantity of data to be sent/received for a given transfer.

The DCD should not attempt to modify any field in an active dTD except the Next Like Pointer, which should only be modified as described in section Managing Transfers with Transfer Descriptors.
Table below shows the Endpoint Transfer Descriptor (dTD).

**Table 42-61. Endpoint Transfer Descriptor (dTD)**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<td>Buffer Pointer (Page 3)</td>
</tr>
<tr>
<td></td>
<td>Reserved</td>
</tr>
<tr>
<td></td>
<td>Buffer Pointer (Page 4)</td>
</tr>
<tr>
<td></td>
<td>Reserved</td>
</tr>
</tbody>
</table>

The following table describes the dTD Pointer.

**Table 42-62. Next dTD Pointer**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-5</td>
<td>Next Transfer Element Pointer. This field contains the physical memory address of the next dTD to be processed. The field corresponds to memory address signals [31:5], respectively.</td>
</tr>
<tr>
<td>4-1</td>
<td>Reserved. Bits reserved for future use and should be set to zero.</td>
</tr>
<tr>
<td>0</td>
<td>Terminate (T). 1=pointer is invalid. 0=Pointer is valid (points to a valid Transfer Element Descriptor). This bit indicates to the Device Controller that there are no more valid entries in the queue.</td>
</tr>
</tbody>
</table>

The following table describes the dTD Token.

**Table 42-63. dTD Token**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>
<td>Reserved. Bit reserved for future use and should be set to zero.</td>
</tr>
<tr>
<td>30-16</td>
<td>Total Bytes. This field specifies the total number of bytes to be moved with this transfer descriptor. This field is decremented by the number of bytes actually moved during the transaction and only on the successful completion of the transaction. The maximum value software may store in the field is 5*4K (5000H). This is the maximum number of bytes 5 page pointers can access. Although it is possible to create a transfer up to 20K this assumes the 1st offset into the first page is 0. When the offset cannot be predetermined, crossing past the 5th page can be guaranteed by limiting the total bytes to 16K**. Therefore, the maximum recommended transfer is 16K (4000H). If the value of the field is zero when the host controller fetches this transfer descriptor (and the active bit is set), the device controller executes a zero-length transaction and retires the transfer descriptor.</td>
</tr>
</tbody>
</table>

Table continues on the next page...
Table 42-63. dTD Token (continued)

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15</td>
<td>Interrupt On Complete (IOC). This bit is used to indicate if USBINT is to be set in response to device controller being finished with this dTD.</td>
</tr>
<tr>
<td>14-12</td>
<td>Reserved. Bits reserved for future use and should be set to zero.</td>
</tr>
<tr>
<td>11-10</td>
<td>Multiplier Override (MultO). This field can be used for transmit ISO's (ie. ISO-IN) to override the multiplier in the QH. This field must be zero for all packet types that are not transmit-ISO. Example: if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultO = 0 [default] Three packets are sent: {Data2(8); Data1(7); Data0(0)} if QH.multiplier = 3; Maximum packet size = 8; Total Bytes = 15; MultO = 2 Two packets are sent: {Data1(8); Data0(7)} For maximal efficiency, software should compute MultO = greatest integer of (Total Bytes / Max. Packet Size) except for the case when Total Bytes = 0; then MultO should be 1. Note: Non-ISO and Non-TX endpoints must set MultO = &quot;00&quot;.</td>
</tr>
<tr>
<td>9-8</td>
<td>Reserved. Bits reserved for future use and should be set to zero.</td>
</tr>
<tr>
<td>7-0</td>
<td>Status. This field is used by the Device Controller to communicate individual command execution states back to the Device Controller software. This field contains the status of the last transaction performed on this qTD. The bit encodings are: Bit Status Field Description 7 Active. 6 Halted. 5 Data Buffer Error. 3 Transaction Error. 4, 2, 0 Reserved.</td>
</tr>
</tbody>
</table>

The table below describes the dTD Buffer Page Pointer List.

Table 42-64. dTD Buffer Page Pointer List

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>

<tbody>
<tr>
<td>31-12</td>
<td>Buffer Pointer. Selects the page offset in memory for the packet buffer. Non virtual memory systems will typically set the buffer pointers to a series of incrementing integers.</td>
</tr>
<tr>
<td>0,11-0</td>
<td>Current Offset. Offset into the 4kb buffer where the packet is to begin.</td>
</tr>
<tr>
<td>1,10-0</td>
<td>Frame Number. Written by the device controller to indicate the frame number in which a packet finishes. This is typically be used to correlate relative completion times of packets on an ISO endpoint.</td>
</tr>
</tbody>
</table>

42.5.6 Device Operational Model

The function of the device operation is to transfer a request in the memory image to and from the Universal Serial Bus.
Using a set of linked list transfer descriptors, pointed to by a queue head, the device controller will perform the data transfers. The following sections explain the use of the device controller from the device controller driver (DCD) point-of-view and further describe how specific USB bus events relate to status changes in the device controller programmer's interface.

### 42.5.6.1 Device Controller Initialization

After hardware reset, the device is disabled until the Run/Stop bit is set to a '1'. In the disabled state, the pull-up on the USB D+ is not active which prevents an attach event from occurring. At a minimum, it is necessary to have the queue heads setup for endpoint zero before the device attach occurs.

Shortly after the device is enabled, a USB reset will occur followed by setup packet arriving at endpoint 0. A Queue head must be prepared so that the device controller can store the incoming setup packet.

In order to initialize a device, the software should perform the following steps:

- Set Controller Mode in the USB.USBMODE register to device mode.
  
  **NOTE**
  Transitioning from host mode to device mode requires a device controller reset before modifying USB.USBMODE.

- Allocate and Initialize device queue heads in system memory.
  - Minimum: Initialize device queue heads 0 Tx & 0 Rx.

  **NOTE**
  All device queue heads for control endpoints must be initialized before the endpoint is enabled. Non-Control device queue heads before the endpoint can be used.

  - For information on device queue heads, refer to section Device Data Structures.
  - Configure USB.ENDPOINTLISTADDR Pointer.
    - For additional information on USB.ENDPOINTLISTADDR, refer to the register table.
  - Enable the microprocessor interrupt associated with the USB core.
    - Recommended: enable all device interrupts including: USBINT, USBERRINT, Port Change Detect, USB Reset Received, DCSuspend.
    - For a list of available interrupts refer to the Interrupt Enable Register (USB_nUSBINTR) and the USB Status Register (USB_nUSBSTS) register tables.
  - Set Run/Stop bit to Run Mode.
After the Run bit is set and the device is connected to a host, a Bus Reset will be issued by host downstream port. The DCD must monitor the reset event and adjust the software state as described in the Bus Reset section of the Port State and Control section below.

**NOTE**

Endpoint 0 is designed as a control endpoint only and does not need to be configured using ENDPTCTRL0 register.

It is also not necessary to prime Endpoint 0 initially because the first packet received will always be a setup packet. The contents of the first setup packet will require a response in accordance with USB device framework (Chapter 9) command set.

### 42.5.6.2 Port State and Control

From a chip or system reset, the device controller enters the *powered* state. A transition from the *powered* state to the *attach* state occurs when the Run/Stop bit is set to a '1'.

After receiving a reset on the bus, the port will enter the *defaultFS* or *defaultHS* state in accordance with the reset protocol described in Appendix C.2 of the USB Specification Rev. 2.0.

The following state diagram depicts the state of a USB 2.0 device.
States *powered, attach, defaultFS/HS, suspendFS/HS* are implemented in the device controller and are communicated to the DCD using the following status bits:

The following table describes the Device Controller State Information Bits.

**Table 42-65. Device Controller State Information Bits**

<table>
<thead>
<tr>
<th>Bit</th>
<th>Register</th>
</tr>
</thead>
<tbody>
<tr>
<td>DCSuspend</td>
<td>USB Status Register (USB_nUSBSTS)</td>
</tr>
<tr>
<td>USB Reset Received</td>
<td>USB Status Register (USB_nUSBSTS)</td>
</tr>
<tr>
<td>Port Change Detect</td>
<td>USB Status Register (USB_nUSBSTS)</td>
</tr>
<tr>
<td>High-Speed Port</td>
<td>Port Status &amp; Control (USB_nPORTSC1)</td>
</tr>
</tbody>
</table>

**Figure 42-28. Device State Diagram**

When the host resets the device returns to the default state.
It is the responsibility of the DCD to maintain a state variable to differentiate between the DefaultFS/HS state and the Address/Configured states. Change of state from Default to Address and the Configured states is part of the enumeration process described in the device framework section of the USB 2.0 Specification.

As a result of entering the Address state, the device address register (DEVICEADDR) must be programmed by the DCD.

Entry into the Configured indicates that all endpoints to be used in the operation of the device have been properly initialized by programming the USB_UOG_ENDPTCTRLx registers and initializing the associated queue heads.

### 42.5.6.2.1 Bus Reset

A bus reset is used by the host to initialize downstream devices.

When a bus reset is detected, the device controller will renegotiate its attachment speed, reset the device address to 0, and notify the DCD by interrupt (assuming the USB Reset Interrupt Enable is set). After a reset is received, all endpoints (except endpoint 0) are disabled and any primed transactions will be cancelled by the device controller. The concept of priming will be clarified below, but the DCD must perform the following tasks when a reset is received:

Clear all setup token semaphores by reading the Endpoint Status (USB_{n}ENDPTSTAT) register and writing the same value back to the Endpoint Status (USB_{n}ENDPTSTAT) register.

Clear all the endpoint complete status bits by reading the Endpoint Complete (USB_{n}ENDPTCOMPLETE) register and writing the same value back to the Endpoint Complete (USB_{n}ENDPTCOMPLETE) register.

Cancel all primed status by waiting until all bits in the Endpoint Prime (USB_{n}ENDPTPRIME) are 0 and then writing 0xFFFFFFFF to Endpoint Flush (USB_{n}ENDPTFLUSH).

Read the reset bit in the Port Status & Control (USB_{n}PORTSC1) register and make sure that it is still active. A USB reset will occur for a minimum of 3 ms and the DCD must reach this point in the reset cleanup before end of the reset occurs, otherwise a hardware reset of the device controller is recommended (rare.)

- A hardware reset can be performed by writing a one to the device controller reset bit in the USBCMD reset. Note: a hardware reset will cause the device to detach from the bus by clearing the Run/Stop bit. Thus, the DCD must completely re-initialize the device controller after a hardware reset.
Free all allocated dTDs because they will no longer be executed by the device controller. If this is the first time the DCD is processing a USB reset event, then it is likely that no dTDs have been allocated.

At this time, the DCD may release control back to the OS because no further changes to the device controller are permitted until a Port Change Detect is indicated.

After a Port Change Detect, the device has reached the default state and the DCD can read the Port Status & Control (USB_nPORTSC1) to determine if the device is operating in FS or HS mode. At this time, the device controller has reached normal operating mode and DCD can begin enumeration according to the USB Chapter 9 - Device Framework.

**NOTE**
The device DCD may use the FS/HS mode information to determine the bandwidth mode of the device.

In some applications, it may not be possible to enable one or more pipes while in FS mode. *Beyond the data rate issue, there is no difference in DCD operation between FS and HS modes.*

### 42.5.6.2.2 Suspend/Resume

The details of suspend and resume are explained in these sections.

#### 42.5.6.2.2.1 Suspend

**Suspend Description**

In order to conserve power, USB devices automatically enter the suspended state when the device has observed no bus traffic for a specified period. When suspended, the USB device maintains any internal status, including its address and configuration. Attached devices must be prepared to suspend at any time they are powered, regardless of if they have been assigned a non-default address, are configured, or neither. Bus activity may cease due to the host entering a suspend mode of its own. In addition, a USB device shall also enter the suspended state when the hub port it is attached to is disabled.

A USB device exits suspend mode when there is bus activity. A USB device may also request the host to exit suspend mode or selective suspend by using electrical signaling to indicate remote wakeup. The ability of a device to signal remote wakeup is optional. If the USB device is capable of remote wakeup signaling, the device must support the ability of the host to enable and disable this capability. When the device is reset, remote wakeup signaling must be disabled.

**Suspend Operational Model**
The device controller moves into the suspend state when suspend signaling is detected or activity is missing on the upstream port for more than a specific period. After the device controller enters the suspend state, the DCD is notified by an interrupt (assuming DC Suspend Interrupt is enabled). When the DCSuspend bit in the Port Status & Control (USB_nPORTSC1) is set to a '1', the device controller is suspended.

DCD response when the device controller is suspended is application specific and may involve switching to low power operation.

Information on the bus power limits in suspend state can be found in USB 2.0 specification.

**NOTE**
Review system level clocking issues defined in section (Ref: Signals-Clocking) for the clocking requirements of a suspended device controller.

### 42.5.6.2.2 Resume

If the device controller is suspended, its operation is resumed when any non-idle signaling is received on its upstream facing port. In addition, the device can signal the system to resume operation by forcing resume signaling to the upstream port.

Resume signaling is sent upstream by writing a '1' to the Resume bit in the Port Status & Control (USB_nPORTSC1) while the device is in suspend state. Sending resume signal to an upstream port should cause the host to issue resume signaling and bring the suspended bus segment (one more devices) back to the active condition.

**NOTE**
Before resume signaling can be used, the host must enable it by using the Set Feature command defined in device framework (chapter 9) of the USB 2.0 Specification.

### 42.5.6.3 Managing Endpoints

The USB 2.0 specification defines an endpoint, also called a device endpoint or an address endpoint as a uniquely addressable portion of a USB device that can source or sink data in a communications channel between the host and the device.

The endpoint address is specified by the combination of the endpoint number and the endpoint direction.
The channel between the host and an endpoint at a specific device represents a data pipe. Endpoint 0 for a device is always a control type data channel used for device discovery and enumeration. Other types of endpoints support by USB include bulk, interrupt, and isochronous. Each endpoint type has specific behavior related to packet response and error handling. More detail on endpoint operation can be found in the USB 2.0 specification.

The USB OTG device controller hardware supports up to 8 endpoint numbers. Each endpoint direction is essentially independent and can be configured with differing behavior in each direction. For example, the DCD can configure endpoint 1-IN to be a bulk endpoint and endpoint 1-OUT to be an isochronous endpoint. This helps to conserve the total number of endpoints required for device operation. The only exception is that control endpoints must use both directions on a single endpoint number to function as a control endpoint. Endpoint 0 is, for example, is always a control endpoint and uses the pair of directions.

Each endpoint direction requires a queue head allocated in memory. To support the 8 endpoint numbers, 16 queue heads are required. The operation of an endpoint and use of queue heads are described later in this document.

### 42.5.6.3.1 Endpoint Initialization

After hardware reset, all endpoints except endpoint zero are uninitialized and disabled. The DCD must configure and enable each endpoint by writing to configuration bit in the USB_UOG_ENDPTCTRLx register.

Each 32-bit USB_UOG_ENDPTCTRLx is split into an upper and lower half. The lower half of USB_UOG_ENDPTCTRLx is used to configure the receive or OUT endpoint and the upper half is likewise used to configure the corresponding transmit or IN endpoint. Control endpoints must be configured the same in both the upper and lower half of the USB_UOG_ENDPTCTRLx register otherwise the behavior is undefined. The following table shows how to construct a configuration word for endpoint initialization. The following table shows the fields and values for the Device Controller Endpoint initialization.

<table>

<td>01 Isochronous</td>
</tr>
<tr>
<td></td>
<td>10 Bulk</td>
</tr>
</tbody>
</table>

Table continues on the next page...
### Stalling

There are two occasions where the device controller may need to return to the host a STALL.

The first occasion is the functional stall, which is a condition set by the DCD as described in the USB 2.0 device framework. A functional stall is only used on non-control endpoints and can be enabled in the device controller by setting the endpoint stall bit in the USB_UOG_ENDPTCTRLx register associated with the given endpoint and the given direction. In a functional stall condition, the device controller will continue to return STALL responses to all transactions occurring on the respective endpoint and direction until the endpoint stall bit is cleared by the DCD.

A protocol stall, unlike a function stall, is used on control endpoints is automatically cleared by the device controller at the start of a new control transaction (setup phase). When enabling a protocol stall, the DCD should enable the stall bits (both directions) as a pair. A single write to the USB_UOG_ENDPTCTRLx register can ensure that both stall bits are set at the same instant.

**NOTE**

Any write to the USB_UOG_ENDPTCTRLx register during operational mode must preserve the endpoint type field (that is, perform a read-modify-write).

The following table shows the response matrix for the Device Controller Stall.

#### Table 42-67. Device Controller Stall Response Matrix

*Table continues on the next page...*
### 42.5.6.3.3 Data Toggle

Data toggle is a mechanism to maintain data coherency between host and device for any given data pipe.

For more information on data toggle, refer to the USB 2.0 specification.

#### 42.5.6.3.3.1 Data Toggle Reset

The DCD may reset the data toggle state bit and cause the data toggle sequence to reset in the device controller by writing a '1' to the data toggle reset bit in the USB_UOG_ENDPTCTRLx register.

This should only be necessary when configuring/initializing an endpoint or returning from a STALL condition.

#### 42.5.6.3.3.2 Data Toggle Inhibit

**NOTE**

This feature is for test purposes only and should never be used during normal device controller operation.

Setting the *data toggle Inhibit bit* active ('1') causes the device controller to ignore the data toggle pattern that is normally sent and accept all incoming data packets regardless of the data toggle state.

In normal operation, the device controller checks the DATA0/DATA1 bit against the data toggle to determine if the packet is valid. If Data PID does not match the data toggle state bit maintained by the device controller for that endpoint, the Data toggle is considered not valid. If the data toggle is not valid, the device controller assumes the packet was already received and discards the packet (not reporting it to the DCD). To prevent the host controller from re-sending the same packet, the device controller will respond to the error packet by acknowledging it with either an ACK or NYET response.

#### 42.5.6.3.3.3 Priming Transmit Endpoints

Priming a transmit endpoint will cause the device controller to fetch the device transfer descriptor (dTD) for the transaction pointed to by the device queue head (dQH).

---

**Table 42-67. Device Controller Stall Response Matrix (continued)**

<table>
<thead>
<tr>
<th>IN/OUT/PING packet received by a control endpoint.</th>
<th>'0'</th>
<th>None.</th>
<th>ACK/NAK/NYET</th>
</tr>
</thead>
</table>

---

*Chapter 42 Universal Serial Bus Controller (USB)*

NXP Semiconductors

i.MX RT1060 Processor Reference Manual, Rev. 2, 12/2019
After the dTD is fetched, it will be stored in the dQH until the device controller completes the transfer described by the dTD. Storing the dTD in the dQH allows the device controller to fetch the operating context needed to handle a request from the host without the need to follow the linked list, starting at the dQH when the host request is received.

After the device has loaded the dTD, the leading data in the packet is stored in a FIFO in the device controller. This FIFO is split into virtual channels so that the leading data can be stored for any endpoint up to the maximum number of endpoints configured at device synthesis time.

After a priming request is complete, an endpoint state of primed is indicated in the USB_UOG_ENDPTSTATUS register. For a primed transmit endpoint, the device controller can respond to an IN request from the host and meet the stringent bus turnaround time of High Speed USB.

Because only the leading data is stored in the device controller FIFO, it is necessary for the device controller to begin filling in behind leading data after the transaction starts. The FIFO must be sized to account for the maximum latency that can be incurred by the system memory bus. More information about FIFO sizing is presented in section 42.5.6.3.3.4

### 42.5.6.3.3.4 Priming Receive Endpoints

Priming receive endpoints is identical to priming of transmit endpoints from the point of view of the DCD. At the device controller the major difference in the operational model is that there is no data movement of the leading packet data simply because the data is to be received from the host.

Note as part of the architecture, the FIFO for the receive endpoints is not partitioned into multiple channels like the transmit FIFO. Thus, the size of the RX FIFO does not scale with the number of endpoints.

### 42.5.6.4 Operational Model For Packet Transfers

All transactions on the USB bus are initiated by the host and in turn, the device must respond to any request from the host within the turnaround time stated in the USB 2.0 Specification.

At USB 1.1 Full or Low Speed rates, this turnaround time was significant and the USB 1.1 device controllers were architected so that the device controller could access main memory or interrupt a host protocol processor in order to respond to the USB 1.1
transaction. The architecture of the USB 2.0 device controller must be different because same methods will not meet USB 2.0 High-speed turnaround time requirements by simply increasing clock rate.

A USB host will send requests to the device controller in an order that can not be precisely predicted as a single pipeline, so it is not possible to prepare a single packet for the device controller to execute. However, the order of packet requests is predictable when the endpoint number and direction is considered. For example, if endpoint 3 (transmit direction) is configured as a bulk pipe, then we can expect the host will send IN requests to that endpoint. This device controller is architected in such a way that it can prepare packets for each endpoint/direction in anticipation of the host request. The process of preparing the device controller to send or receive data in response to host initiated transaction on the bus is referred to as "priming" the endpoint. This term will be used throughout the following documentation to describe the device controller operation so the DCD can be architected properly use priming. Further, note that the term "flushing" is used to describe the action of clearing a packet that was queued for execution.

42.5.6.4.1 Interrupt/Bulk Endpoint Operational Model

The behaviors of the device controller for interrupt and bulk endpoints are identical. All valid IN and OUT transactions to bulk pipes will handshake with a NAK unless the endpoint had been primed. Once the endpoint has been primed, data delivery will commence.

A dTD will be retired by the device controller when the packets described in the transfer descriptor have been completed. Each dTD describes N packets to be transferred according to the USB Variable Length transfer protocol. The formula and table on the following page describe how the device controller computes the number and length of the packets to be sent/received by the USB vary according to the total number of bytes and maximum packet length.

With Zero Length Termination (ZLT) = 0

\[ N = \text{INT}(\text{Number Of Bytes}/\text{Max. Packet Length}) + 1 \]

With Zero Length Termination (ZLT) = 1

\[ N = \text{MAXINT}(\text{Number Of Bytes}/\text{Max. Packet Length}) \]

</tbody>
</table>

**NOTE**

The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.

TX-dTD is complete when:

- All packets described dTD were successfully transmitted. *** Total bytes in dTD will equal zero when this occurs.

RX-dTD is complete when:

- All packets described in dTD were successfully received. *** Total bytes in dTD will equal zero when this occurs.
- A short packet (number of bytes < maximum packet length) was received. *** This is a successful transfer completion; DCD must check Total Bytes in dTD to determine the number of bytes that are remaining. From the total bytes remaining in the dTD, the DCD can compute the actual bytes received.
- A long packet was received (number of bytes > maximum packet size) OR (total bytes received > total bytes specified). *** This is an error condition. The device controller will discard the remaining packet, and set the Buffer Error bit in the dTD. In addition, the endpoint will be flushed and the USBERR interrupt will become active.

On the successful completion of the packet(s) described by the dTD, the active bit in the dTD will be cleared and the next pointer will be followed when the Terminate bit is clear. When the Terminate bit is set, the device controller will flush the endpoint/direction and cease operations for that endpoint/direction.

On the unsuccessful completion of a packet (see long packet above), the dQH will be left pointing to the dTD that was in error. In order to recover from this error condition, the DCD must properly reinitialize the dQH by clearing the active bit and update the nextTD pointer before attempting to re-prime the endpoint.
NOTE
All packet level errors such as a missing handshake or CRC error will be retried automatically by the device controller.

There is no required interaction with the DCD for handling such errors.

42.5.6.4.1.1 Interrupt/Bulk Endpoint Bus Response Matrix

The table below shows the response matrix for Interrupt/Bulk Endpoint Bus.

<table>
<thead>
<tr>
<th></th>
<th>Stall</th>
<th>Not Primed</th>
<th>Primed</th>
<th>Underflow</th>

<td>N/A</td>
</tr>
<tr>
<td>Invalid</td>
<td>Ignore</td>
<td>Ignore</td>
<td>Ignore</td>
<td>Ignore</td>
<td>Ignore</td>
</tr>
</tbody>
</table>

NOTE
BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

42.5.6.4.2 Control Endpoint Operation Model

This section details the setup phase, data phase, status phase, and the control endpoint bus response matrix.

42.5.6.4.2.1 Setup Phase

All requests to a control endpoint begin with a setup phase followed by an optional data phase and a required status phase. The device controller will always accept the setup phase unless the setup lockout is engaged.

The setup lockout will engage so that future setup packets are ignored. Lockout of setup packets ensures that while software is reading the setup packet stored in the queue head, that data is not written as it is being read potentially causing an invalid setup packet.
The setup lockout mechanism can be disabled and a new tripwire type semaphore will ensure that the setup packet payload is extracted from the queue head without being corrupted by an incoming setup packet. This is the preferred behavior because ignoring repeated setup packets due to long software interrupt latency would be a compliance issue.

- Disable Setup Lockout by writing 1 to Setup Lockout Mode (SLOM) in USB Device Mode (USB_nUSBMODE). (once at initialization). Setup lockout is not necessary when using the tripwire as described below.

**NOTE**
Leaving the Setup Lockout Mode As 0 will result in pre-2.3 hardware behavior.

- After receiving an interrupt and inspecting Endpoint Setup Status (USB_nENDPTSETUPSTAT) to determine that a setup packet was received on a particular pipe:
  a. Write 1 to clear corresponding bit Endpoint Setup Status (USB_nENDPTSETUPSTAT).
  b. Write 1 to Setup Tripwire (SUTW) in USB Command Register (USB_nUSBCMD) register.
  c. Duplicate contents of dQH.SetupBuffer into local software byte array.
  d. Read Setup TripWire (SUTW) in USB Command Register (USB_nUSBCMD) register. (if set - continue; if cleared - goto 2)
  e. Write 0 to clear Setup Tripwire (SUTW) in USB Command Register (USB_nUSBCMD) register.
  f. Process setup packet using local software byte array copy and execute status/handshake phases.

**NOTE**
After receiving a new setup packet the status and/or handshake phases may still be pending from a previous control sequence. These should be flushed & deallocated before linking a new status and/or handshake dTD for the most recent setup packet.

### 42.5.6.4.2.2 Data Phase

Following the setup phase, the DCD must create a device transfer descriptor for the data phase and prime the transfer.

After priming the packet, the DCD must verify a new setup packet has not been received by reading the USB.ENDPTSETUPSTAT register immediately verifying that the prime had completed. A prime will complete when the associated bit in the Endpoint Prime (USB_nENDPTPRIME) register is zero and the associated bit in the Endpoint Status
(USB\_n\_ENDPTSTAT) register is a one. If a prime fails, ie. The Endpoint Prime (USB\_n\_ENDPTPRIME) bit goes to zero and the Endpoint Status (USB\_n\_ENDPTSTAT) bit is not set, then the prime has failed. This can only be due to improper setup of the dQH, dTD or a setup arriving during the prime operation. If a new setup packet is indicated after the ENDPTPRIME bit is cleared, then the transfer descriptor can be freed and the DCD must reinterpret the setup packet.

Should a setup arrive after the data stage is primed, the device controller will automatically clear the prime status (Endpoint Status (USB\_n\_ENDPTSTAT)) to enforce data coherency with the setup packet.

NOTE

- The MULT field in the dQH must be set to "00" for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

42.5.6.4.2.3 Status Phase

Similar to the data phase, the DCD must create a transfer descriptor (with byte length equal zero) and prime the endpoint for the status phase.

The DCD must also perform the same checks of the USB.ENDPTSETUPSTAT as described above in the data phase.

NOTE

- The MULT field in the dQH must be set to 00 for bulk, interrupt, and control endpoints.
- Error handling of data phase packets is the same as bulk packets described previously.

42.5.6.4.2.4 Control Endpoint Bus Response Matrix

Shown in the following table is the device controller response to packets on a control endpoint according to the device controller state.

The table below shows the response matrix for the Control Endpoint Bus.

<table>
<thead>
<tr>
<th>Token Type</th>
<th>Endpoint State</th>
<th>Setup Lockout</th>

</tbody>
</table>

BS Error = Force Bit Stuff Error

NYET/ACK - NYET unless the Transfer Descriptor has packets remaining according to the USB variable length protocol then ACK.

SYSERR - System error should never occur when the latency FIFOs are correctly sized and the DCD is responsive.

42.5.6.4.3 Isochronous Endpoint Operational Model

Isochronous endpoints are used for real-time scheduled delivery of data and their operational model is significantly different than the host throttled Bulk, Interrupt, and Control data pipes.

Real time delivery by the device controller will be accomplished by the following:

- Exactly MULT Packets per (micro) Frame are transmitted/received. Note: MULT is a two-bit field in the device Queue Head. The variable length packet protocol is not used on isochronous endpoints.
- NAK responses are not used. Instead, zero length packets are sent in response to an IN request to an unprimed endpoints. For unprimed RX endpoints, the response to an OUT transaction is to ignore the packet within the device controller.
- Prime requests always schedule the transfer described in the dTD for the next (micro) frame. If the ISO-dTD is still active after that frame, then the ISO-dTD will be held ready until executed or canceled by the DCD.

An EHCI compatible host controller uses the periodic frame list to schedule data exchanges to Isochronous endpoints. The operational model for device mode does not use such a data structure. Instead, the same dTD used for Control/Bulk/Interrupt endpoints is also used for isochronous endpoints. The difference is in the handling of the dTD.

The first difference between bulk and ISO-endpoints is that priming an ISO-endpoint is a delayed operation such that an endpoint will become primed only after a SOF is received. After the DCD writes the prime bit, the prime bit will be cleared as usual to indicate to software that the device controller completed a priming the dTD for transfer. Internal to the design, the device controller hardware masks that prime start until the next frame boundary. This behavior is hidden from the DCD but occurs so that the device controller can match the dTD to a specific (micro)frame.
Another difference with isochronous endpoints is that the transaction must wholly complete in a (micro)frame. Once an ISO transaction is started in a (micro)frame it will retire the corresponding dTD when MULT transactions occur or the device controller finds a fulfillment condition.

The transaction error bit set in the status field indicates a fulfillment error condition. When a fulfillment error occurs, the frame after the transfer failed to complete wholly, the device controller will force retire the ISO-dTD and move to the next ISO-dTD.

It is important to note that fulfillment errors are only caused due to partially completed packets. If no activity occurs to a primed ISO-dTD, the transaction will stay primed indefinitely. This means it is up to software to discard transmit ISO-dTDs that pile up from a failure of the host to move the data.

Finally, the last difference with ISO packets is in the data level error handling. When a CRC error occurs on a received packet, the packet is not retried similar to bulk and control endpoints. Instead, the CRC is noted by setting the Transaction Error bit and the data is stored as usual for the application software to sort out.

- TX Packet Retired
  - MULT counter reaches zero.
  - Fulfillment Error [Transaction Error bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT

**NOTE**
For TX-ISO, MULT Counter can be loaded with a lesser value in the dTD Multiplier Override field in hardware versions 2.3 and later. If the Multiplier Override is zero, the MULT Counter is initialized to the Multiplier in the QH.

- RX Packet Retired:
  - MULT counter reaches zero.
  - Non-MDATA Data PID is received**
    - ** Exit criteria only valid in hardware version 2.3 or later. Previous to hardware version 2.3, any PID sequence that did not match the MULT field exactly would be flagged as a transaction error due to PID mismatch or fulfillment error.
  - Overflow Error:
    - Packet received is > maximum packet length. [Buffer Error bit is set]
    - Packet received exceeds total bytes allocated in dTD. [Buffer Error bit is set]
  - Fulfillment Error [Transaction Error bit is set]
    - # Packets Occurred > 0 AND # Packets Occurred < MULT
  - CRC Error [Transaction Error bit is set]
NOTE
For ISO, when a dTD is retired, the next dTD is primed for the next frame. For continuous (micro)frame to (micro)frame operation the DCD should ensure that the dTD linked-list is out ahead of the device controller by at least two (micro)frames.

42.5.6.4.3.1 Isochronous Pipe Synchronization

When it is necessary to synchronize an isochronous data pipe to the host, the (micro) frame number (USB_UOG_FRINDEX register) can be used as a marker.

To cause a packet transfer to occur at a specific (micro) frame number [N], the DCD should interrupt on SOF during frame N-1. When the USB_UOG_FRINDEX=N-1, the DCD must write the prime bit. The device controller will prime the isochronous endpoint in (micro) frame N-1 so that the device controller will execute delivery during (micro) frame N.

NOTE
Priming an endpoint towards the end of (micro) frame N-1 will not guarantee delivery in (micro) frame N. The delivery may actually occur in (micro) frame N+1 if device controller does not have enough time to complete the prime before the SOF for packet N is received.

42.5.6.4.3.2 Isochronous Endpoint Bus Response Matrix

The following table shows the response matrix for the Isochronous Endpoint Bus.

<table>
<thead>
<tr>

1. BS Error = Force Bit Stuff Error
NULL Packet = Zero Length Packet
42.5.6.5 Managing Queue Heads

The following figure shows the End Point Queue Head.

![End Point Queue Head Diagram](image)

The device queue head (dQH) points to the linked list of transfer tasks, each depicted by the device Transfer Descriptor (dTD). An area of memory pointed to by USB.ENDPOINTLISTADDR contains a group of all dQH's in a sequential list as shown in Figure 42-29. The even elements in the list of dQH's are used for receive endpoints (OUT/SETUP) and the odd elements are used for transmit endpoints (IN/INTERRUPT). Device transfer descriptors are linked head to tail starting at the queue head and ending at a terminate bit. Once the dTD has been retired, it will no longer be part of the linked list from the queue head. Therefore, software is required to track all transfer descriptors because pointers will no longer exist within the queue head once the dTD is retired (see section Software Link Pointers).

In addition to the current and next pointers and the dTD overlay examined in section Operational Model For Packet Transfers, the dQH also contains the following parameters for the associated endpoint: Multipler, Maximum Packet Length, Interrupt On Setup. The complete initialization of the dQH including these fields is demonstrated in the next section.

42.5.6.5.1 Queue Head Initialization

One device queue head must be initialized for each active endpoint.

To initialize a device queue head:
• Write the wMaxPacketSize field as required by the USB Chapter 9 or application specific protocol.
• Write the multiplier field to 0 for control, bulk, and interrupt endpoints. For ISO endpoints, set the multiplier to 1, 2, or 3 as required bandwidth and in conjunction with the USB Chapter 9 protocol.

**NOTE**
In FS mode, the multiplier field can only be 1 for ISO endpoints.

• Write the next dTD Terminate bit field to 1.
• Write the Active bit in the status field to 0.
• Write the Halt bit in the status field to 0.

**NOTE**
The DCD must only modify dQH if the associated endpoint is not primed and there are no outstanding dTD's.

### 42.5.6.5.2 Operational Model For Setup Transfers

As discussed in section Control Endpoint Operation Model, setup transfer requires special treatment by the DCD. A setup transfer does not use a dTD but instead stores the incoming data from a setup packet in an 8-byte buffer within the dQH.

Upon receiving notification of the setup packet, the DCD should handle the setup transfer as demonstrated here:

1. Copy setup buffer contents from dQH - RX to software buffer.
2. Acknowledge setup backup by writing a "1" to the corresponding bit in ENDPTSETUPSTAT.

**NOTE**
• The acknowledge must occur before continuing to process the setup packet.
• After the acknowledge has occurred, the DCD must not attempt to access the setup buffer in the dQH - RX. Only the local software copy should be examined.

3. Check for pending data or status dTD's from previous control transfers and flush if any exist as discussed in section Flushing/De-priming an Endpoint.
4. Decode setup packet and prepare data phase [optional] and status phase transfer as required by the USB Chapter 9 or application specific protocol.
NOTE
It is possible for the device controller to receive setup packets before previous control transfers complete. Existing control packets in progress must be flushed and the new control packet completed.

42.5.6.6 Managing Transfers with Transfer Descriptors

42.5.6.6.1 Software Link Pointers

It is necessary for the DCD software to maintain head and tail pointers to the for the linked list of dTDs for each respective queue head.

This is necessary because the dQH only maintains pointers to the current working dTD and the next dTD to be executed. The operations described in next section for managing dTD will assume the DCD can use reference the head and tail of the dTD linked list. The following figure shows the Software Link Pointers.

![Software Link Pointers Diagram]

**Figure 42-30. Software Link Pointers**

NOTE
To conserve memory, the reserved fields at the end of the dQH can be used to store the Head & Tail pointers, but it still remains the responsibility of the DCD to maintain the pointers.

42.5.6.6.2 Building a Transfer Descriptor

Before a transfer can be executed from the linked list, a dTD must be built to describe the transfer.
Use the following procedure for building dTDs.

Allocate 8-DWord dTD block of memory aligned to 8-DWord boundaries. Example: bit address 4:0 would be equal to "00000"

Write the following fields:

1. Initialize first 7 DWords to 0.
2. Set the terminate bit to 1.
3. Fill in total bytes with transfer size.
4. Set the interrupt on complete if desired.
5. Initialize the status field with the active bit set to 1 and all remaining status bits set to 0.
6. Fill in buffer pointer page 0 and the current offset to point to the start of the data buffer.
7. Initialize buffer pointer page 1 through page 4 to be one greater than each of the previous buffer pointer.

42.5.6.6.3 Executing A Transfer Descriptor

To safely add a dTD, the DCD must be follow this procedure which will handle the event where the device controller reaches the end of the dTD list at the same time a new dTD is being added to the end of the list.

Determine whether the link list is empty: Check DCD driver to see if pipe is empty (internal representation of linked-list should indicate if any packets are outstanding).

- Case 1: Link list is empty
  a. Write dQH next pointer AND dQH terminate bit to 0 as a single DWord operation.
  b. Clear active & halt bit in dQH (in case set from a previous error).
  c. Prime endpoint by writing 1 to correct bit position in Endpoint Prime (USB_endptprime).
- Case 2: Link list is not empty
  a. Add dTD to end of linked list.
  b. Read correct prime bit in Endpoint Prime (USB_endptprime)- if 1 DONE.
  c. Set ATDTW bit in USBCMD register to 1.
  d. Read correct status bit in Endpoint Status (USB_endptstat). (store in tmp. variable for later)
  e. Read ATDTW bit in USBCMD register.
     - If 0 goto 3.
     - If 1 continue to 6.
  f. Write ATDTW bit in USBCMD register to 0.
  g. If status bit read in (3) is 1 DONE.
h. If status bit read in (3) is 0 then Goto Case 1: Step 1.

42.5.6.6.4 Transfer Completion

After a dTD has been initialized and the associated endpoint primed the device controller will execute the transfer upon the host-initiated request. The DCD will be notified with a USB interrupt if the Interrupt On Complete bit was set or alternately, the DCD can poll the endpoint complete register to find when the dTD had been executed. After a dTD has been executed, DCD can check the status bits to determine success or failure.

**NOTE**

Multiple dTD can be completed in a single endpoint complete notification. After clearing the notification, DCD must search the dTD linked list and retire all dTDs that have finished (Active bit cleared).

By reading the status fields of the completed dTDs, the DCD can determine if the transfers completed successfully. Success is determined with the following combination of status bits:

- Active = 0
- Halted = 0
- Transaction Error = 0
- Data Buffer Error = 0

Should any combination other than the one shown above exist, the DCD must take proper action. Transfer failure mechanisms are indicated in the Device Error Matrix.

In addition to checking the status bit the DCD must read the Transfer Bytes field to determine the actual bytes transferred. When a transfer is complete, the Total Bytes transferred is by decremented by the actual bytes transferred. For Transmit packets, a packet is only complete after the actual bytes reaches zero, but for receive packets, the host may send fewer bytes in the transfer according the USB variable length packet protocol.

42.5.6.6.5 Flushing/De-priming an Endpoint

It is necessary for the DCD to flush to de-prime one more endpoints on a USB device reset or during a broken control transfer.

There may also be application specific requirements to stop transfers in progress. The following procedure can be used by the DCD to stop a transfer in progress:

1. Write a '1' to the corresponding bit(s) in Endpoint Flush (USB_nENDPTFLUSH).
2. Wait until all bits in Endpoint Flush (USB_nENDPTFLUSH) are '0'.
Software note: this operation may take a large amount of time depending on the USB bus activity. It is not desirable to have this wait loop within an interrupt service routine.

3. Read **Endpoint Status (USB_nENDPTSTAT)** to ensure that for all endpoints commanded to be flushed, that the corresponding bits are now '0'. If the corresponding bits are '1' after step #2 has finished, then the flush failed as described in the following:

- **Explanation:** In very rare cases, a packet is in progress to the particular endpoint when commanded flush using **Endpoint Flush (USB_nENDPTFLUSH)**. A safeguard is in place to refuse the flush to ensure that the packet in progress completes successfully. The DCD may need to repeatedly flush any endpoints that fail to flush be repeating steps 1-3 until each endpoint is successfully flushed.

### 42.5.6.6.6 Device Error Matrix

The following table summarizes packet errors that are not automatically handled by the Device Controller.

<table>
<thead>
<tr>
<th>Error</th>
<th>Direction</th>
<th>Packet Type</th>
<th>Data Buffer Error Bit</th>
<th>Transaction Error Bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overflow **</td>
<td>RX</td>
<td>Any</td>
<td>1</td>
<td>0</td>
</tr>
<tr>
<td>ISO Packet Error</td>
<td>RX</td>
<td>ISO</td>
<td>0</td>
<td>1</td>
</tr>
<tr>
<td>ISO Fulfillment Error</td>
<td>Both</td>
<td>ISO</td>
<td>0</td>
<td>1</td>
</tr>
</tbody>
</table>

Notice that the device controller handles all errors on Bulk/Control/Interrupt Endpoints except for a data buffer overflow. However, for ISO endpoints, errors packets are not retried and errors are tagged as indicated. The table below describes the errors.

<table>
<thead>
<tr>
<th>Error</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overflow</td>
<td>Number of bytes received exceeded max. packet size or total buffer length. <strong>This error will also set the Halt bit in the dQH and if there are dTDs remaining in the linked list for the endpoint, then those will not be executed.</strong></td>
</tr>
<tr>
<td>ISO Packet Error</td>
<td>CRC Error on received ISO packet. Contents not guaranteed to be correct.</td>
</tr>
<tr>
<td>ISO Fulfillment Error</td>
<td>Host failed to complete the number of packets defined in the dQH mult field within the given (micro)frame. For scheduled data delivery the DCD may need to readjust the data queue because a fulfillment error will cause Device Controller to cease data transfers on the pipe for one (micro)frame. During the &quot;dead&quot; (micro)frame, the Device Controller reports error on the pipe and primes for the following frame.</td>
</tr>
</tbody>
</table>
42.5.6.7 Servicing Interrupts

The interrupt service routine must consider that there are high-frequency, low-frequency operations, and error operations and order accordingly.

42.5.6.7.1 High-Frequency Interrupts

High frequency interrupts in particular should be handled in the order below. The most important of these is listed first because the DCD must acknowledge a setup buffer in the timeliest manner possible.

The table below describes the High frequency interrupt events.

Table 42-75. High Frequency Interrupt Events

<table>
<thead>
<tr>
<th>Execution Order</th>
<th>Interrupt</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>1a</td>
<td>USB Interrupt - USB.ENDPTSETUPSTATUS</td>
<td>Copy contents of setup buffer and acknowledge setup packet (as indicated in Figure 42-29 shows the End Point Queue Head). Process setup packet according to USB 2.0 Chapter 9 or application specific protocol.</td>
</tr>
<tr>
<td>1b</td>
<td>USB Interrupt$^1$ - USB.ENDPTCOMPLETE</td>
<td>Handle completion of dTD as indicated in Figure 42-29 shows the End Point Queue Head.</td>
</tr>
<tr>
<td>2</td>
<td>SOF Interrupt</td>
<td>Action as deemed necessary by application. This interrupt may not have a use in all applications.</td>
</tr>
</tbody>
</table>

1. It is likely that multiple interrupts to stack up on any call to the Interrupt Service Routine AND during the Interrupt Service Routine.

42.5.6.7.2 Low-Frequency Interrupts

The low frequency interrupts can be handled in any order because they do not occur often in comparison to the high-frequency interrupts.

The table below shows the Low frequency interrupt events.

Table 42-76. Low Frequency Interrupt Events

<table>
<thead>
<tr>
<th>Interrupt</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port Change</td>
<td>Change software state information.</td>
</tr>
<tr>
<td>Sleep Enable (Suspend)</td>
<td>Change software state information. Low power handling as necessary.</td>
</tr>
<tr>
<td>Reset Received</td>
<td>Change software state information. Abort pending transfers.</td>
</tr>
</tbody>
</table>
### 42.5.6.7.3 Error Interrupts

Error interrupts will be least frequent and should be placed last in the interrupt service routine.

The following table shows the error interrupt events.

<table>
<thead>
<tr>
<th>Interrupt</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>USB Error Interrupt</td>
<td>This error is redundant because it combines USB Interrupt and an error status in the dTD. The DCD will more aptly handle packet-level errors by checking dTD status field upon receipt of USB Interrupt (w/ USB.ENDPTCOMPLETE).</td>
</tr>
<tr>
<td>System Error</td>
<td>Unrecoverable error. Immediate Reset of core; free transfers buffers in progress and restart the DCD.</td>
</tr>
</tbody>
</table>

#### 42.6 USB Non-Core Memory Map/Register Definition

There are two kinds of registers in the USB module: USB core registers and USB non-core registers. USB core registers are used to control USB core functions, and more independent of USB features. Each USB controller core has its own core registers. USB non-core registers are additional to USB core registers, and more dependent on USB features. i.MX series products vary in non-core registers.

This section describes only the USB non-core registers. For detailed descriptions of USB core registers, please refer to Register Interface.

**NOTE**

- For reserved bits, please preserve the value when writing (read its reset value, then write this value back)
- "USB_UOG1_", "USB_UOG2_" prefix in register name indicates it is a core register for OTG1/OTG2 controller core respectively.
- USBNC_USB_" prefix in register name indicates it is a USB non-core register.

**USBNC memory map**

i.MX RT1060 Processor Reference Manual, Rev. 2, 12/2019

NXP Semiconductors
42.6.2 USB OTG2 Control Register (USBNC_USB_OTG2_CTRL)

The USB OTG2 control register controls the integration specific features of the USB OTG2 module. These features are not directly related to the USB functionality, but control special features, interfacing on the USB ports, as well as power control and wake-up functionality.

Address: 402E_0000h base + 804h offset = 402E_0804h

</tbody>
</table>
| 23–16 | TX FIFO Buffer size is: \(2^{\text{TXCHANADD}}\) * 4 Bytes.  
These bits are set to '08h', so buffer size is 256*4 Bytes.  
For the OTG controller operating in device mode, this is the FIFO buffer size per endpoint. As the OTG controller has 8 TX endpoint, there are 8 of these buffers.  
For the OTG controller operating in host mode, or for Host-only controller, the entire buffer memory is used as a single TX buffer. Therefore, there is only 1 of this buffer |
| 15–8  | This field is reserved. |
| TXBURST | Default burst size for memory to TX buffer transfer.  
This is reset value of TXPBURST bits in USB core regisiter USB\_\_n\_BURSTSIZE.  
Please see Programmable Burst Size (USB\_\_nBURSTSIZE).

42.7.8 General Purpose Timer #0 Controller (USB\_nGPTIMEROCTRL)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enabled.

Interrupt status bit is TI0 bit in n_USBSTS register (See USB Status Register (USB\_nUSBSTS) ), interrupt enable bit is TIE0 bit in n_USBINTR register. (See Interrupt Enable Register (USB\_nUSBINTR) .)

This register contains the control for this countdown timer and a data field can be queried to determine the running count value. This timer has granularity on 1 us and can be programmed to a little over 16 seconds. There are two counter modes which are described in the register table below. When the timer counter value transitions to zero, an interrupt could be generated if enable.

Interrupt status bit is TI1 bit in USB_n_USBSTS register (See USB Status Register (USB_nUSBSTS) ), interrupt enable bit is TIE1 bit in n_USBINTR register (See Interrupt Enable Register (USB_nUSBINTR) )

Address: $402E_{0000h} \text{ base} + 8Ch \text{ offset} + (512d \times i)$, where $i=0d$ to $1d$

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>11–8 N_PCC</td>
<td>Number of Ports per Companion Controller</td>
</tr>
<tr>
<td></td>
<td>This field indicates the number of ports supported per internal Companion Controller. It is used to indicate the port routing configuration to the system software. For example, if N_PORTS has a value of 6 and N_CC has a value of 2 then N_PCC could have a value of 3. The convention is that the first N_PCC ports are assumed to be routed to companion controller 1, the next N_PCC ports to companion controller 2, etc. In the previous example, the N_PCC could have been 4, where the first 4 are routed to companion controller 1 and the last two are routed to companion controller 2. The number in this field must be consistent with N_PORTS and N_CC. These bits are '0000b' in all controller core.</td>
</tr>
<tr>
<td>7–5</td>
<td>This field is reserved. Reserved</td>
</tr>
<tr>
<td>4 PPC</td>
<td>Port Power Control</td>
</tr>
<tr>
<td></td>
<td>This field indicates whether the host controller implementation includes port power control. A one indicates the ports have port power switches. A zero indicates the ports do not have port power switches. The value of this field affects the functionality of the Port Power field in each port status and control register.</td>
</tr>
<tr>
<td>N_PORTS</td>
<td>Number of downstream ports. This field specifies the number of physical downstream ports implemented on this host controller. The value of this field determines how many port registers are addressable in the Operational Register. Valid values are in the range of 1h to Fh. A zero in this field is undefined. These bits are always set to '0001b' because all controller cores are Single-Port Host.</td>
</tr>
</tbody>
</table>
42.7.15 Host Controller Capability Parameters
(USB_nHCCPARAMS)

This register identifies multiple mode control (time-base bit functionality), addressing capability.

Address: 402E_0000h base + 108h offset + (512d × i), where i=0d to 1d

**USB_nHCCPARAMS field descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31–16 - | This field is reserved.  
Reserved |
| 15–8 EECP | EHCI Extended Capabilities Pointer.  
This field indicates the existence of a capabilities list. A value of 00h indicates no extended capabilities are implemented. A non-zero value in this register indicates the offset in PCI configuration space of the first EHCI extended capability. The pointer value must be 40h or greater if implemented to maintain the consistency of the PCI header defined for this class of device.  
**NOTE:** These bits are set '00h' in all controller core. |
| 7–4 IST | Isochronous Scheduling Threshold.  
This field indicates, relative to the current position of the executing host controller, where software can reliably update the isochronous schedule. When bit [7] is zero, the value of the least significant 3 bits indicates the number of micro-frames a host controller can hold a set of isochronous data structures (one or more) before flushing the state. When bit [7] is a one, then host software assumes the host controller may cache an isochronous data structure for an entire frame.  
These bits are set '00h' in all controller core. |
| 3 - | This field is reserved.  
Reserved |

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 2 ASP | Asynchronous Schedule Park Capability  
If this bit is set to a one, then the host controller supports the park feature for high-speed queue heads in the Asynchronous Schedule. The feature can be disabled or enabled and set to a specific level by using the Asynchronous Schedule Park Mode Enable and Asynchronous Schedule Park Mode Count fields in the USBCMD register.  
**NOTE:** ASP bit reset value: '00b' for OTG controller core, '11b' for Host-only controller core. |
| 1 PFL | Programmable Frame List Flag  
If this bit is set to zero, then the system software must use a frame list length of 1024 elements with this host controller. The USBCMD register Frame List Size field is a read-only register and must be set to zero.  
If set to a one, then the system software can specify and use a smaller frame list and configure the host controller via the USBCMD register Frame List Size field. The frame list must always be aligned on a 4K-page boundary. This requirement ensures that the frame list is always physically contiguous.  
This bit is set '1b' in all controller core. |
| 0 ADC | 64-bit Addressing Capability  
This bit is set '0b' in all controller core, no 64-bit addressing capability is supported. |

### 42.7.16 Device Controller Interface Version (USB\_nDCIVERSION)

This register indicates the two-byte BCD encoding of the device controller interface version number.

Address: 402E\_0000h base + 120h offset + (512d × i), where i=0d to 1d

**15**

**FS\_2**  
Frame List Size - (Read/Write or Read Only). [host mode only]  
This field is Read/Write only if Programmable Frame List Flag in the HCCPARAMS registers is set to one.  
This field specifies the size of the frame list that controls which bits in the Frame Index Register should be used for the Frame List Current index.  

**NOTE:** This field is made up from USBCMD bits 15, 3 and 2.

**14**

**ATDTW**  
Add dTD TripWire - Read/Write. [device mode only]  
This bit is used as a semaphore to ensure proper addition of a new dTD to an active (primed) endpoint's linked list. This bit is set and cleared by software.  
This bit would also be cleared by hardware when state machine is hazard region for which adding a dTD to a primed endpoint may go unrecognized.

**13**

**SUTW**  
Setup TripWire - Read/Write. [device mode only]  
This bit is used as a semaphore to ensure that the setup data payload of 8 bytes is extracted from a QH by the DCD without being corrupted. If the setup lockout mode is off (SLOM bit in USB core register n_USBMODE, see **USB Device Mode** (USB\_nUSBMODE) ) then there is a hazard when new setup data arrives while the DCD is copying the setup data payload from the QH for a previous setup packet. This bit is set and cleared by software.  
This bit would also be cleared by hardware when a hazard detected.

**12**

This field is reserved.  
Reserved

**11**

**ASPE**  
Asynchronous Schedule Park Mode Enable - Read/Write.  
If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this bit defaults to a 1h and is R/W. Otherwise the bit must be a zero and is RO. Software uses this bit to enable or disable Park mode. When this bit is one, Park mode is enabled. When this bit is a zero, Park mode is disabled.  

**NOTE:** ASPE bit reset value: ‘0b’ for OTG controller.

**10**

This field is reserved.  
Reserved

**9–8**

**ASP**  
Asynchronous Schedule Park Mode Count - Read/Write.  
If the Asynchronous Park Capability bit in the HCCPARAMS register is a one, then this field defaults to 3h and is R/W. Otherwise it defaults to zero and is Read-Only. It contains a count of the number of successive transactions the host controller is allowed to execute from a high-speed queue head on the

<td>DCSuspend - R/WC. When a controller enters a suspend state from an active state, this bit will be set to a one. The device controller clears the bit upon exiting from a suspend state. Only used in device operation mode.</td>
</tr>
<tr>
<td>7 SRI</td>
<td>SOF Received - R/WC. When the device controller detects a Start Of (micro) Frame, this bit will be set to a one. When a SOF is extremely late, the device controller will automatically set this bit to indicate that an SOF was expected. Therefore, this bit will be set roughly every 1ms in device FS mode and every 125ms in HS mode and will be synchronized to the actual SOF that is received. Because the device controller is initialized to FS before connect, this bit will be set at an interval of 1ms during the prelude to connect and chirp. In host mode, this bit will be set every 125us and can be used by host controller driver as a time base. Software writes a 1 to this bit to clear it.</td>
</tr>
<tr>
<td>6 URI</td>
<td>USB Reset Received - R/WC. When the device controller detects a USB Reset and enters the default state, this bit will be set to a one. Software can write a 1 to this bit to clear the USB Reset Received status bit. Only used in device operation mode.</td>
</tr>
</tbody>
</table>

Table continues on the next page...
### USB_nUSBSTS field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 5 AAI | Interrupt on Async Advance - R/WC.  
System software can force the host controller to issue an interrupt the next time the host controller advances the asynchronous schedule by writing a one to the Interrupt on Async Advance Doorbell bit in the n_USBCMD register. This status bit indicates the assertion of that interrupt source.  
Only used in host operation mode. |
| 4 SEI | System Error- R/WC.  
This bit is will be set to '1b' when an Error response is seen to a read on the system interface. |
| 3 FRI | Frame List Rollover - R/WC.  
The Host Controller sets this bit to a one when the Frame List Index rolls over from its maximum value to zero. The exact value at which the rollover occurs depends on the frame list size. For example, if the frame list size (as programmed in the Frame List Size field of the USB_n_USBCMD register) is 1024, the Frame Index Register rolls over every time FRINDEX [13] toggles. Similarly, if the size is 512, the Host Controller sets this bit to a one every time FHINDEX [12] toggles.  
Only used in host operation mode. |
| 2 PCI | Port Change Detect - R/WC.  
The Host Controller sets this bit to a one when on any port a Connect Status occurs, a Port Enable/Disable Change occurs, or the Force Port Resume bit is set as the result of a J-K transition on the suspended port.  
The Device Controller sets this bit to a one when the port controller enters the full or high-speed operational state. When the port controller exits the full or high-speed operation states due to Reset or Suspend events, the notification mechanisms are the USB Reset Received bit and the DCSuspend bits respectively. |
| 1 UEI | USB Error Interrupt (USBERRINT) - R/WC.  
When completion of a USB transaction results in an error condition, this bit is set by the Host/Device Controller. This bit is set along with the USBINT bit, if the TD on which the error interrupt occurred also had its interrupt on complete (IOC) bit set.  
The device controller detects resume signaling only. |
| 0 UI | USB Interrupt (USBINT) - R/WC.  
This bit is set by the Host/Device Controller when the cause of an interrupt is a completion of a USB transaction where the Transfer Descriptor (TD) has an interrupt on complete (IOC) bit set.  
This bit is also set by the Host/Device Controller when a short packet is detected. A short packet is when the actual number of bytes received was less than the expected number of bytes. |
42.7.20 Interrupt Enable Register (USB_nUSBINTR)

The interrupts to software are enabled with this register. An interrupt is generated when a bit is set and the corresponding interrupt source is active. The USB Status register (n_USBSTS) still shows interrupt sources even if they are disabled by the n_USBINTR register, allowing polling of interrupt events by the software.

42.7.21  USB Frame Index (USB_nFRINDEX)

This register is used by the host controller to index the periodic frame list. The register updates every 125 microseconds (once each micro-frame). Bits [N: 3] are used to select a particular entry in the Periodic Frame List during periodic schedule execution. The number of bits used for the index depends on the size of the frame list as set by system software in the Frame List Size field in the n_USBCMD register.

This register must be written as a DWord. Byte writes produce undefined results. This register cannot be written unless the Host Controller is in the 'Halted' state as indicated by the HCHalted bit. A write to this register while the Run/Stop hit is set to a one produces undefined results. Writes to this register also affect the SOF value.

In device mode this register is read only and, the device controller updates the FRINDEX [13:3] register from the frame number indicated by the SOF marker. Whenever a SOF is received by the USB bus, FRINDEX [13:3] will be checked against the SOF marker. If FRINDEX [13:3] is different from the SOF marker, FRINDEX [13:3] will be set to the SOF value and FRINDEX [2:0] will be set to zero (that is, SOF for 1 ms frame). If FRINDEX [13:3] is equal to the SOF value, FRINDEX [2:0] will be increment (that is, SOF for 125 us micro-frame.).

Address: 402E_0000h base + 14Ch offset + (512d × i), where i=0d to 1d

</tbody>
</table>

The value, in this register, increments at the end of each time frame (micro-frame). Bits [N: 3] are used for the Frame List current index. This means that each location of the frame list is accessed 8 times (frames or micro-frames) before moving to the next index.

The following illustrates values of N based on the value of the Frame List Size field in the USBCMD register, when used in host mode.

<table>

42.7.22 Frame List Base Address (USB_nPERIODICLISTBASE)

Host Controller only

This 32-bit register contains the beginning address of the Periodic Frame List in the system memory. HCD loads this register prior to starting the schedule execution by the Host Controller. The memory structure referenced by this physical memory pointer is assumed to be 4-Kbyte aligned. The contents of this register are combined with the Frame Index Register (USB_n_FRINDEX) to enable the Host Controller to step through the Periodic Frame List in sequence.

Address: 402E_0000h base + 154h offset + (512d × i), where i=0d to 1d

42.7.23 Device Address (USB_nDEVICEADDR)

Device Controller only

The upper seven bits of this register represent the device address. After any controller reset or a USB reset, the device address is set to the default address (0). The default address will match all incoming addresses. Software shall reprogram the address after receiving a SET_ADDRESS descriptor.
Address: 402E_0000h base + 154h offset + (512d × i), where i=0d to 1d

<td>Device Address. These bits correspond to the USB device address</td>
</tr>
<tr>
<td>24 USBADRA</td>
<td>Device Address Advance. Default=0. When this bit is '0', any writes to USBADR are instantaneous. When this bit is written to a '1' at the same time or before USBADR is written, the write to the USBADR field is staged and held in a hidden register. After an IN occurs on endpoint 0 and is ACKed, USBADR will be loaded from the holding register. Hardware will automatically clear this bit on the following conditions: 1) IN is ACKed to endpoint 0. (USBADR is updated from staging register). 2) OUT/SETUP occur to endpoint 0. (USBADR is not updated). 3) Device Reset occurs (USBADR is reset to 0). <strong>NOTE:</strong> After the status phase of the SET_ADDRESS descriptor, the DCD has 2 ms to program the USBADR field. This mechanism will ensure this specification is met when the DCD can not write of the device address within 2ms from the SET_ADDRESS status phase. If the DCD writes the USBADR with USBADRA=1 after the SET_ADDRESS data phase (before the prime of the status phase), the USBADR will be programmed instantly at the correct time and meet the 2ms USB requirement.</td>

### 42.7.27 TX FIFO Fill Tuning (USB_nTXFILLTUNING)

The fields in this register control performance tuning associated with how the host controller posts data to the TX latency FIFO before moving the data onto the USB bus. The specific areas of performance include the how much data to post into the FIFO and an estimate for how long that operation should take in the target system.

**Definitions:**

- \( T_0 \) = Standard packet overhead
- \( T_1 \) = Time to send data payload
- \( T_{ff} \) = Time to fetch packet into TX FIFO up to specified level.
- \( T_s \) = Total Packet Flight Time (send-only) packet \( T_s = T_0 + T_1 \)
- \( T_p \) = Total Packet Time (fetch and send) packet \( T_p = T_{ff} + T_0 + T_1 \)

Upon discovery of a transmit (OUT/SETUP) packet in the data structures, host controller checks to ensure \( T_p \) remains before the end of the [micro)frame. If so it proceeds to pre-fill the TX FIFO. If at anytime during the pre-fill operation the time remaining the [micro)frame is < \( T_s \) then the packet attempt ceases and the packet is tried at a later time. Although this is not an error condition and the host controller will eventually recover, a
mark will be made the scheduler health counter to note the occurrence of a "back-off" event. When a back-off event is detected, the partial packet fetched may need to be discarded from the latency buffer to make room for periodic traffic that will begin after the next SOF. Too many back-off events can waste bandwidth and power on the system bus and thus should be minimized (not necessarily eliminated). Back-offs can be minimized with use of the n_TSCHHEALTH (Tff) described below.

**NOTE**
The reset value could vary from instance to instance. Please see the detail in bit field description and ignore reset value in summary table in this case!

</tr>
<tr>
<td>29</td>
<td></td>
<td></td>
<td></td>
<td>This register controls the number of data bursts that are posted to the TX latency FIFO in host mode before the packet begins on to the bus. The minimum value is 2 and this value should be as low as possible to maximize USB performance. A higher value can be used in systems with unpredictable latency and/or insufficient bandwidth where the FIFO may underrun because the data transferred from the latency FIFO to USB occurs before it can be replenished from system memory. This value is ignored if the Stream Disable bit in USB_n_USBMODE register is set. Default value is '0Ah for OTG controller core.</td>
</tr>

</tr>
<tr>
<td>26</td>
<td></td>
<td></td>
<td></td>
<td>This register increments when the host controller fails to fill the TX latency FIFO to the level programmed by TXFIFOTHRES before running out of time to send the packet before the next Start-Of-Frame. This health counter measures the number of times this occurs to provide feedback to selecting a proper TXSCHOH. Writing to this register will clear the counter and this counter will max. at 31. Default value is '00h' for OTG controller core.</td>
</tr>
<tr>
<td>25</td>
<td></td>
<td></td>
<td>12–8 TXSCHOH</td>
<td>Scheduler Overhead. (Read/Write) [Default = 0]</td>
</tr>
<tr>
<td>24</td>
<td></td>
<td></td>
<td></td>
<td>This register adds an additional fixed offset to the schedule time estimator described above as Tff. As an approximation, the value chosen for this register should limit the number of back-off events captured in the TXSCHHEALTH to less than 10 per second in a highly utilized bus. Choosing a value that is too high for this register is not desired as it can needlessly reduce USB utilization. The time unit represented in this register is 1.267us when a device is connected in High-Speed Mode. The time unit represented in this register is 6.333us when a device is connected in Low/Full Speed Mode. Default value is '08h' for OTG controller core.</td>

42.7.31 Port Status & Control (USB_nPORTSC1)

Host Controller

A host controller could implement one to eight port status and control registers. The number is determined by N_PORTs bits in HWSPARAMs register (please see Host Controller Structural Parameters (USB_nHCSPARAMS) ). Software could read this parameter register to determine how many ports need service.

All controller cores on this product are Single-Port, so there is only one port status and control register for each controller core.
This register is only reset by power on reset or controller core reset. The initial conditions of a port are:

- No device connected
- Port disabled

If the port supports power control, this state remains until port power is supplied (by software).

Device Controller

A controller operating in device mode has only port register one (PORTSC1) and it does not support power control in that mode. Port control in device mode is only used for status port reset, suspend, and current connect status. It is also used to initiate test mode or force signaling and allows software to put the PHY into low power suspend mode and disable the PHY clock.

<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–30 PTS_1</td>
<td><strong>NOTE:</strong> All USB port interface modes are listed in this field description, but not all are supported. For detail feature of each controller core, please see <a href="#">Features</a>. The behaviour is unknown when unsupported interface mode is selected.</td>
</tr>
</tbody>
</table>
| 29 STS | Serial Transceiver Select  
1 Serial Interface Engine is selected  
0 Parallel Interface signals is selected  
Serial Interface Engine can be used in combination with UTMI+/ULPI physical interface to provide FS/LS signaling instead of the parallel interface signals.  
When this bit is set ‘1b’, serial interface engine will be used instead of parallel interface signals.  
This bit has no effect unless PTS bits is set to select UTMI+/ULPI interface.  
The Serial/USB1.1 PHY/IC-USB will use the serial interface engine for FS/LS signaling regardless of this bit value. |
| 28 PTW | Parallel Transceiver Width  
This bit has no effect if serial interface engine is used.  
For OTG1/OTG2 core, it is Read-Only. Reset value is ‘1b’.  
0 Select the 8-bit UTMI interface [60MHz]  
1 Select the 16-bit UTMI interface [30MHz] |
| 27–26 PSPD | Port Speed - Read Only.  
This register field indicates the speed at which the port is operating.  
00 Full Speed  
01 Low Speed  
10 High Speed  
11 Undefined |
| 25 PTS_2 | See description at bits 31-30 |
| 24 PFSC | Port Force Full Speed Connect - Read/Write. Default = 0b.  
When this bit is set to ‘1b’, the port will be forced to only connect at Full Speed, It disables the chirp sequence that allows the port to identify itself as High Speed.  
1 Forced to full speed  
0 Normal operation |
| 23 PHCD | PHY Low Power Suspend - Clock Disable (PLPSCD) - Read/Write. Default = 0b.  
When this bit is set to ‘1b’, the PHY clock is disabled. Reading this bit will indicate the status of the PHY clock.  
**NOTE:** The PHY clock cannot be disabled if it is being used as the system clock.  
In device mode, The PHY can be put into Low Power Suspend when the device is not running (USBCMD Run/Stop=0b) or the host has signalled suspend (PORTSC1 SUSPEND=1b). PHY Low power suspend will be cleared automatically when the host initials resume. Before forcing a resume from the device, the device controller driver must clear this bit.  
In host mode, the PHY can be put into Low Power Suspend when the downstream device has been put into suspend mode or when no downstream device is connected. Low power suspend is completely under the control of software. |

*Table continues on the next page...*
### USB_nPORTSC1 field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 1     | Disable PHY clock  
|       | Enable PHY clock  |
| 22    | Wake on Over-current Enable (WKOC_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to over-current conditions as wake-up events. This field is zero if Port Power(Port Status & Control (USB_nPORTSC1)) is zero. |
| 21    | Wake on Disconnect Enable (WKDSCNNT_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to device disconnects as wake-up events. This field is zero if Port Power(Port Status & Control (USB_nPORTSC1)) is zero or in device mode. |
| 20    | Wake on Connect Enable (WKCNNT_E) - Read/Write. Default = 0b. Writing this bit to a one enables the port to be sensitive to device connects as wake-up events. This field is zero if Port Power(Port Status & Control (USB_nPORTSC1)) is zero or in device mode. |
| 19–16 | Port Test Control - Read/Write. Default = 0000b. Refer to Port Test Mode for the operational model for using these test modes and the USB Specification Revision 2.0, Chapter 7 for details on each test mode. The FORCE_ENABLE_FS and FORCE ENABLE LS are extensions to the test mode support specified in the EHCI specification. Writing the PTC field to any of the FORCE_ENABLE_{HS/FS/LS} values will force the port into the connected and enabled state at the selected speed. Writing the PTC field back to TEST_MODE_DISABLE will allow the port state machines to progress normally from that point. **NOTE:** Low speed operations are not supported as a peripheral device. Any other value than zero indicates that the port is operating in test mode. Value Specific Test  
|       | TEST_MODE_DISABLE

**USB_nPORTSC1 field descriptions (continued)**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This bit unconditionally goes to a 0 when the configured bit in the CONFIGFLAG register makes a 0 to 1 transition. This bit unconditionally goes to 1 whenever the Configured bit is zero System software uses this field to release ownership of the port to a selected host controller (in the event that the attached device is not a high-speed device). Software writes a one to this bit when the attached device is not a high-speed device. A one in this bit means that an internal companion controller owns and controls the port. Port owner handoff is not supported in all controller cores, therefore this bit will always be 0.</td>
<td></td>
</tr>
<tr>
<td><strong>12</strong> PP</td>
<td>Port Power (PP)-Read/Write or Read Only. The function of this bit depends on the value of the Port Power Switching (PPC) field in the HCSPARAMS register. The behavior is as follows: PPC Operation 0 1b Read Only - Host controller does not have port power control switches. Each port is hard-wired to power. 1 1b/0b - Read/Write. OTG controller requires port power control switches. This bit represents the current setting of the switch (0=off, 1=on). When power is not available on a port (that is, PP equals a 0), the port is non-functional and will not report attaches, detaches, etc. When an over-current condition is detected on a powered port and PPC is a one, the PP bit in each affected port may be transitional by the host controller driver from a one to a zero (removing power from the port). This feature is implemented in all controller cores (PPC = 1).</td>
</tr>
<tr>
<td><strong>11–10</strong> LS</td>
<td>Line Status-Read Only. These bits reflect the current logical levels of the D+ (bit 11) and D- (bit 10) signal lines. In host mode, the use of linestate by the host controller driver is not necessary (unlike EHCI), because the port controller state machine and the port routing manage the connection of LS and FS. In device mode, the use of linestate by the device controller driver is not necessary. The encoding of the bits are: Bits [11:10] Meaning 00 SE0 10 J-state 01 K-state 11 Undefined</td>
</tr>
<tr>
<td><strong>9</strong> HSP</td>
<td>High-Speed Port - Read Only. Default = 0b. When the bit is one, the host/device connected to the port is in high-speed mode and if set to zero, the host/device connected to the port is not in a high-speed mode. <strong>NOTE:</strong> HSP is redundant with PSPD(bit 27, 26) but remained for compatibility.</td>
</tr>
<tr>
<td><strong>8</strong> PR</td>
<td>Port Reset - Read/Write or Read Only. Default = 0b. In Host Mode: Read/Write. 1=Port is in Reset. 0=Port is not in Reset. Default 0. When software writes a one to this bit the bus-reset sequence as defined in the USB Specification Revision 2.0 is started. This bit will automatically change to zero after the reset sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the reset duration is timed in the driver.</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>7</strong> SUSP</td>
<td></td>
</tr>
</tbody>
</table>
Suspend - Read/Write or Read Only. Default = 0b.  
1=Port in suspend state. 0=Port not in suspend state.  
In Host Mode: Read/Write.  
Port Enabled Bit and Suspend bit of this register define the port states as follows:  
Bits [Port Enabled, Suspend] Port State  
0x Disable  
10 Enable  
11 Suspend  
When in suspend state, downstream propagation of data is blocked on this port, except for port reset. The blocking occurs at the end of the current transaction if a transaction was in progress when this bit was written to 1. In the suspend state, the port is sensitive to resume detection. Note that the bit status does not change until the port is suspended and that there may be a delay in suspending a port if there is a transaction currently in progress on the USB.  
The host controller will unconditionally set this bit to zero when software sets the Force Port Resume bit to zero. The host controller ignores a write of zero to this bit.  
If host software sets this bit to a one when the port is not enabled (that is, Port enabled bit is a zero) the results are undefined.  
This field is zero if Port Power(Port Status & Control (USB_nPORTSC1)) is zero in host mode.  
In Device Mode: Read Only.  
In device mode this bit is a read only status bit.  

| 6 FPR |  
Force Port Resume - Read/Write. 1= Resume detected/driven on port. 0=No resume (K-state) detected/driven on port. Default = 0.  
In Host Mode:  
Software sets this bit to one to drive resume signaling. The Host Controller sets this bit to one if a J-to-K transition is detected while the port is in the Suspend state. When this bit transitions to a one because a J-to-K transition is detected, the Port Change Detect bit in the USBSTS register is also set to one. This bit will automatically change to zero after the resume sequence is complete. This behavior is different from EHCI where the host controller driver is required to set this bit to a zero after the resume duration is timed in the driver.  
Note that when the Host controller owns the port, the resume sequence follows the defined sequence documented in the USB Specification Revision 2.0. The resume signaling (Full-speed 'K') is driven on the port as long as this bit remains a one. This bit will remain a one until the port has switched to the high-speed idle. Writing a zero has no effect because the port controller will time the resume operation, clear the bit the port control state switches to HS or FS idle.  
This field is zero if Port Power(Port Status & Control (USB_nPORTSC1)) is zero in host mode.  
This bit is not-EHCI compatible.  
In Device mode:

### USB\_nPORTSC1 field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>After the device has been in Suspend State for 5ms or more, software must set this bit to one to drive resume signaling before clearing. The Device Controller will set this bit to one if a J-to-K transition is detected while the port is in the Suspend state. The bit will be cleared when the device returns to normal operation. Also, when this bit will be cleared because a K-to-J transition detected, the Port Change Detect bit in the USBSSTS register is also set to one.</td>
<td></td>
</tr>
<tr>
<td>OCC</td>
<td>Over-current Change-R/WC. Default=0. This bit is set ‘1b’ by hardware when there is a change to Over-current Active. Software can clear this bit by writing a one to this bit position.</td>
</tr>
<tr>
<td>OCA</td>
<td>Over-current Active-Read Only. Default 0. This bit will automatically transition from one to zero when the over current condition is removed. 1 This port currently has an over-current condition 0 This port does not have an over-current condition.</td>
</tr>
<tr>
<td>PEC</td>
<td>Port Enable/Disable Change-R/WC. 1=Port enabled/disabled status has changed. 0=No change. Default = 0. In Host Mode: For the root hub, this bit is set to a one only when a port is disabled due to disconnect on the port or due to the appropriate conditions existing at the EOF2 point (See Chapter 11 of the USB Specification). Software clears this by writing a one to it. This field is zero if Port Power(Port Status &amp; Control (USB_nPORTSC1)) is zero. In Device mode: The device port is always enabled, so this bit is always ‘0b’.</td>
</tr>
<tr>
<td>PE</td>
<td>Port Enabled/Disable-Read/Write. 1=Enable. 0=Disable. Default 0. In Host Mode: Ports can only be enabled by the host controller as a part of the reset and enable. Software cannot enable a port by writing a one to this field. Ports can be disabled by either a fault condition (disconnect event or other fault condition) or by the host software. Note that the bit status does not change until the port state actually changes. There may be a delay in disabling or enabling a port due to other host controller and bus events. When the port is disabled, (0b) downstream propagation of data is blocked except for reset. This field is zero if Port Power(Port Status &amp; Control (USB_nPORTSC1)) is zero in host mode. In Device Mode: The device port is always enabled, so this bit is always ‘1b’.</td>
</tr>
<tr>
<td>CSC</td>
<td>Connect Status Change-R/WC. 1=Change in Current Connect Status. 0=No change. Default 0. In Host Mode: Indicates a change has occurred in the port’s Current Connect Status. The host/device controller sets this bit for all changes to the port device connect status, even if system software has not cleared an existing connect status change. For example, the insertion status changes twice before system software has cleared the changed condition, hub hardware will be ‘setting’ an already-set bit (that is, the bit will remain set). Software clears this bit by writing a one to it. This field is zero if Port Power(Port Status &amp; Control (USB_nPORTSC1)) is zero in host mode. In Device Mode: This bit is undefined in device controller mode.</td>
</tr>
</tbody>

## USB\_nPORTSC1 field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 0 CCS | Current Connect Status-Read Only.  
In Host Mode:  
1=Device is present on port. 0=No device is present. Default = 0. This value reflects the current state of the port, and may not correspond directly to the event that caused the Connect Status Change bit (Bit 1) to be set.  
This field is zero if Port Power(Port Status & Control (USB\_nPORTSC1)) is zero in host mode.  
In Device Mode:  
1=Attached. 0=Not Attached. Default=0. A one indicates that the device successfully attached and is operating in either high speed or full speed as indicated by the High Speed Port bit in this register. A zero indicates that the device did not attach successfully or was forcibly disconnected by the software writing a zero to the Run bit in the USBCMD register. It does not state the device being disconnected or suspended. |

### 42.7.32 On-The-Go Status & control (USB\_nOTGSC)

This register is available only in OTG controller core. It has four sections:

- OTG Interrupt enables (Read/Write)
- OTG Interrupt status (Read/Write to Clear)
- OTG Status inputs (Read Only)
- OTG Controls (Read/Write)

The status inputs are debounced using a 1 ms time constant. Values on the status inputs that do not persist for more than 1 ms does not cause an update of the status input register, or cause an OTG interrupt.

See also **USB Device Mode (USB\_nUSBMODE)** register.

<td>Stream Disable Mode. (0 - Inactive [default]; 1 - Active)</td>
</tr>
</tbody>
</table>

Device Mode: Setting to a ‘1’ disables double priming on both RX and TX for low bandwidth systems. This mode ensures that when the RX and TX buffers are sufficient to contain an entire packet that the standard double buffering scheme is disabled to prevent overruns/underruns in bandwidth limited systems. Note: In High Speed Mode, all packets received are responded to with a NYET handshake when stream disable is active.

Host Mode: Setting to a ‘1’ ensures that overruns/underruns of the latency FIFO are eliminated for low bandwidth systems where the RX and TX buffers are sufficient to contain the entire packet. Enabling stream disable also has the effect of ensuring the TX latency is filled to capacity before the packet is launched onto the USB.

**NOTE:** Time duration to pre-fill the FIFO becomes significant when stream disable is active. See TX FIFO Fill Tuning (USB_nTXFILLTUNING) and TXTFILLTUNING [MPH Only] to characterize the adjustments needed for the scheduler when using this feature.

<td>Setup Endpoint Status. For every setup transaction that is received, a corresponding bit in this register is set to one. Software must clear or acknowledge the setup transfer by writing a one to a respective bit after it has read the setup data from Queue head. The response to a setup packet as in the order of operations and total response time is crucial to limit bus time outs while the setup lock our mechanism is engaged. See Managing Endpoints in the Device Operational Model.</td>
</tr>
<tr>
<td>This register is only used in device mode.</td>
<td></td>
</tr>
</tbody>
</table>
42.7.35 Endpoint Prime (USB_nENDPTPRIME)

This register is only used in device mode.

When software sets the prime bit for a given endpoint, the device controller loads the transfer descriptor, pointed to by the queue head, such that the endpoint is ready to transmit or receive when the host sends a request (IN/OUT token). The endpoint will NAK all requests from the host until the endpoint is primed. The controller will automatically re-prime the endpoint with a new transfer descriptor when one is found via the next_dtd pointer of the current transfer descriptor. Hence, the prime bit must only be set by software when a descriptor is added to the queue head.

| **22–20** - | This field is reserved.  
Reserved |
| **19–18** TXT | TX Endpoint Type - Read/Write  
00 - Control  
Endpoint0 is fixed as a Control End Point. |
| **17** - | This field is reserved.  
Reserved |
| **16** TXS | TX Endpoint Stall - Read/Write  
0 End Point OK [Default]  
1 End Point Stalled  
Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. It continues returning STALL until the bit is cleared by software or it is automatically cleared upon receipt of a new SETUP request.  
After receiving a SETUP request, this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.  
**NOTE:** There is a slight delay (50 clocks max.) between the endptsetupstat being cleared and hardware continuing to clear this bit. In most systems it is unlikely the DCD software will observe this delay. However, should the dcd observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a newsetup has been received by checking the associated endptsetupstat bit. |

| 23 TXE | TX Endpoint Enable  
0 Disabled [Default]  
1 Enabled  
An Endpoint should be enabled only after it has been configured. |
| 22 TXR | TX Data Toggle Reset (WS)  
Write 1 - Reset PID Sequence  
Whenever a configuration event is received for this Endpoint, software must write a one to this bit in order to synchronize the data PID’s between the Host and device. |
| 21 TXI | TX Data Toggle Inhibit  
0 PID Sequencing Enabled. [Default]  
1 PID Sequencing Disabled.  
This bit is only used for test and should always be written as zero. Writing a one to this bit causes this endpoint to ignore the data toggle sequence and always transmit DATA0 for a data packet. |
| 20 - | This field is reserved. Reserved |
| 19–18 TXT | TX Endpoint Type - Read/Write  
00 Control  
01 Isochronous  
10 Bulk  
11 Interrupt |
| 17 TXD | TX Endpoint Data Source - Read/Write  
0 Dual Port Memory Buffer/DMA Engine [DEFAULT]  
Should always be written as 0. |
| 16 T XS | TX Endpoint Stall - Read/Write  
0 End Point OK  
1 End Point Stalled  
This bit will be cleared automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDP TSETUPSTAT bit is cleared.  
Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints.  
**NOTE:** [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDP TSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit. |

This bit is set automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared.

Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints.

**NOTE:** [CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.

---

### 42.7.43 Endpoint Control 4 (USB\_nENDPTCTRL4)

This is endpoint control register for endpoint 4 in device operation mode.

**NOTE**

If one endpoint direction is enabled and the paired endpoint of opposite direction is disabled then the unused direction type must be changed from the default control-type to any other type (that is Bulk-type). leaving an unconfigured endpoint control causes undefined behavior for the data pid tracking on the active endpoint/direction.

<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Description</td>
<td>This bit is set automatically upon receipt of a SETUP request if this Endpoint is configured as a Control Endpoint and this bit will continue to be cleared by hardware until the associated ENDPTSETUPSTAT bit is cleared. Software can write a one to this bit to force the endpoint to return a STALL handshake to the Host. This control will continue to STALL until this bit is either cleared by software or automatically cleared as above for control endpoints.</td>
</tr>
<tr>
<td><strong>NOTE:</strong></td>
<td>[CONTROL ENDPOINT TYPES ONLY]: there is a slight delay (50 clocks max) between the ENDPTSETUPSTAT begin cleared and hardware continuing to clear this bit. In most systems, it is unlikely the DCD software will observe this delay. However, should the DCD observe that the stall bit is not set after writing a one to it then follow this procedure: continually write this stall bit until it is set or until a new setup has been received by checking the associated endptsetupstat bit.</td>

43.2 USB PHY Overview

The chip contains 2 integrated USB 2.0 PHY macrocells capable of connecting to USB host/device systems at the USB low-speed (LS) rate of 1.5 Mbits/s, full-speed (FS) rate of 12 Mbits/s or at the USB 2.0 high-speed (HS) rate of 480 Mbits/s.

The integrated PHY provides a standard UTM interface. The USB_{n}_{DN} and USB_{n}_{DP} pins connect directly to a USB connector.

The following subsections describe the external interfaces, internal interfaces, major blocks, and programmable registers that comprise the integrated USB 2.0 PHY.
43.3 Operation

The UTM provides a 16-bit interface to the USB controller. This interface is clocked at 30 MHz.

- The digital portions of the USBPHY block include the UTMI, digital transmitter, digital receiver, and the programmable registers.
- The analog transceiver section comprises an analog receiver and an analog transmitter, as shown in Figure 43-1.

43.3.1 UTMI

The UTMI block handles the line_state bits, reset buffering, suspend distribution, transceiver speed selection, and transceiver termination selection.

The PLL supplies a 120 MHz signal to all of the digital logic. The UTMI block does a final divide-by-four to develop the 30 MHz clock used in the interface.

43.3.2 Digital Transmitter

The digital transmitter receives the 16-bit transmit data from the USB controller and handles the tx_valid, tx_validh and tx_ready handshake.

In addition, it contains the transmit serializer that converts the 16-bit parallel words at 30 MHz to a single bitstream at 480 Mbit for high-speed or 12 Mbit for full-speed or 1.5 Mbit for low-speed. It does this while implementing the bit-stuffing algorithm and the NRZI encoder that are used to remove the DC component from the serial bitstream. The output of this encoder is sent to the low-speed (LS), full-speed (FS) or high-speed (HS) drivers in the analog transceiver section’s transmitter block.

43.3.3 Digital Receiver

The digital receiver receives the raw serial bitstream from the low speed (LS) differential transceiver, full speed (FS) differential transceiver, and a 9X, 480 MHz sampled data from the high speed (HS) differential transceiver.

As the phase of the USB host transmitter shifts relative to the local PLL, the receiver section’s HS DLL tracks these changes to give a reliable sample of the incoming 480 Mbit/s bitstream. Since this sample point shifts relative to the PLL phase used by the digital logic, a rate-matching elastic buffer is provided to cross this clock domain.
boundary. Once the bitstream is in the local clock domain, an NRZI decoder and bit unstuffer restore the original payload data bitstream and pass it to a deserializer and holding register. The receive state machine handles the rx_valid, rx_validh, and handshake with the USB controller. The handshake is not interlocked, in that there is no rx_ready signal coming from the controller. The controller must take each 16-bit value as presented by the PHY. The receive state machine provides an rx_active signal to the controller that indicates when it is inside a valid packet (SYNC detected, and so on).
43.3.4  Analog Receiver

The analog receiver comprises five differential receivers, two single-ended receivers, and a 9X, 480 MHz HS data sampling module, as shown in the figure below and described further in this section.

![Figure 43-1. USB 2.0 PHY Analog Transceiver Block Diagram](image)

43.3.4.1  HS Differential Receiver

The high-speed differential receiver is both a differential analog receiver and threshold comparator. Its output is a one if the differential signal is greater than a 0-V threshold.
Otherwise, its output is 0. Its purpose is to discriminate the ± 400-mV differential voltage resulting from the high-speed drivers current flow into the dual 45Ω terminations found on each pin of the differential pair. The envelope or squelch detector, described below, ensures that the differential signal has sufficient magnitude to be valid. The HS differential receiver tolerates up to 500 mV of common mode offset.

### 43.3.4.2 Squelch Detector

The squelch detector is a differential analog receiver and threshold comparator.

Its output is 1, if the differential magnitude is less than a nominal 100 mV threshold. Otherwise, its output is 0.

Its purpose is to invalidate the HS differential receiver when the incoming signal is simply too low to receive reliably.

### 43.3.4.3 LS/FS Differential Receiver

The low-speed/full-speed differential receiver is both a differential analog receiver and threshold comparator.

The crossover voltage falls between 1.3 V and 2.0 V. Its output is 1, when the USB\_n\_DP line is above the crossover point and the USB\_n\_DN line is below the crossover point. The digital receiver section decodes the receiver data into J or K state according to the speed.

### 43.3.4.4 HS Disconnect Detector

It is a differential analog receiver and threshold comparator. It outputs high when differential magnitude is greater than a nominal 575-mV threshold. Otherwise, it outputs low.

### 43.3.4.5 USB Plugged-In Detector

The USB plugged-in detector looks for both USB\_n\_DP and USB\_n\_DN to be high. There is a pair of large on-chip pullup resistors (200 KΩ) that hold both USB\_n\_DP and USB\_n\_DN high when the USB cable is not attached. The USB plugged-in detector signals a 0 in this case.
When operating in device mode, the upstream port in host/hub interface contains a 15 KΩ pulldown resistor which could easily override the 200 KΩ pullup resistor. When plugged in, at least one signal in the pair will be low, which will force the plugged-in detector's output high.

43.3.4.6 Single-Ended USB_DP Receiver

The single-ended USB_n_DP receiver output is high whenever the USB_n_DP input is above its nominal 1.8 V threshold.

43.3.4.7 Single-Ended USB_DN Receiver

The single-ended USB_n_DN receiver output is high whenever the USB_n_DN input is above its nominal 1.8 V threshold.

43.3.4.8 9X Oversample Module

The 9X oversample module uses nine identically spaced phases of the 480 MHz clock to sample a high speed bit data. The squelch signal is sampled only 1X.

43.3.5 Analog Transmitter

The analog transmitter comprises two differential drivers: one for high-speed signaling and one for full-speed signaling. It also contains the switchable 1.5 KΩ pullup resistor.

See Figure 43-1.

43.3.5.1 Switchable High-Speed 45Ω Termination Resistors

High-speed current mode differential signaling requires good 90 Ω differential termination at each end of the USB cable. This results from switching in 45 Ω terminating resistors from each signal line to ground at each end of the cable.

Because each signal is parallel terminated with 45 Ω at each end, each driver sees a 22.5 Ω load. This load impedance is much too low for full-speed signaling levels—hence the need for switchable high-speed terminating resistors. Switchable trimming resistors are provided to tune the actual termination resistance of each device, as shown in Figure
The HW_USBPHY_TX_TXCAL45DP bit field, for example, allows one of 16 trimming resistor values to be placed in parallel with the 45Ω terminator on the USB_n_DP signal.

43.3.5.2 Low-Speed/Full-Speed Differential Driver

The low-speed/full-speed differential drivers are essentially low-impedance pulldown devices that are switched in a differential mode for low-speed or full-speed signaling, that is, either one or the other device is turned on to signal the "J" state or the "K" state.

43.3.5.3 High-Speed Differential Driver

The high-speed differential driver receives a 17.78 mA current from the constant current source (Iref) and essentially steers it down either the USB_DP signal or the USB_DN signal or alternatively to ground.

This current will produce approximately a 400 mV drop across the 22.5 Ω termination seen by the driver when it is steered onto one of the signal lines. The approximately 17.78 mA current source is referenced back to the integrated voltage-band-gap (Vbg) circuit. The Iref, Ibias, and V to I circuits are shared with the integrated battery charger.

43.3.5.4 Switchable 1.5KΩ USB_DP Pullup Resistor

This product contains a switchable 1.5 KΩ pullup resistor on the USB_n_DP signal.

This resistor is switched on to indicate to the host/hub controller that a full-speed-capable device is on the USB cable, powered on, and ready. This resistor is switched off at power-on reset so the host does not recognize a USB device until the processor software enables the announcement of a full-speed device.
43.3.5.5 Switchable 15KΩ USB_DP Pulldown Resistor

This product contains a switchable 15 KΩ pulldown resistor on both USB_n_DP and USB_n_DN signals. This is used in host mode to indicate to the device controller that a host is present.

![USB 2.0 PHY Transmitter Block Diagram](image)

**Figure 43-2. USB 2.0 PHY Transmitter Block Diagram**
43.3.6 Recommended Register Configuration for USB Certification

The register settings in this section are recommended for passing USB certification.

The following settings lower the J/K levels to certifiable limits:

\[
\begin{align*}
    \text{HW}_\text{USBPHY}_\text{TX}_\text{TXCAL45DP} &= 0x0 \\
    \text{HW}_\text{USBPHY}_\text{TX}_\text{TXCAL45DN} &= 0x0 \\
    \text{HW}_\text{USBPHY}_\text{TX}_\text{D_CAL} &= 0x7
\end{align*}
\]

43.3.7 Charger detection

The USB charger detector is a block that detects whether the upstream-facing device is connected to a down-stream facing charger, either a dedicated USB charger or a host charger.

The USB charger detector is comprised of two sub-blocks, namely the USB data-pin contact detector and the charger detector.

This section details those two sub-blocks and gives the software flow of USB charger detection. Finally, this chapter discusses the detection of a USB charger in case of a dead battery.

43.3.7.1 Charger detect control table

Before we dive into the details of the detectors, we show the logic table of the control signals to give the user an overall picture of the charger detector.

</tr>
</tbody>
</table>
43.3.7.2 Data pin contact detector

According to Battery Charging Specification (rev 1.2), USB plugs and receptacles are designed such that when the plug is inserted into the receptacle, the power pins make contact before the data pins make contact. Therefore, there is inevitably a time interval during which $USB_n_{\text{VBUS}}$ has been observed by the device while the $USB_n_{\text{DP}}$ and $USB_n_{\text{DN}}$ pins are not still pending for contact. The USB data pin contact detector is designed to give the software an indication of the contact of the data pins.

To enable the USB data pin contact detector, the user should set the CHK_CONTACT bit of the USB1_CHRG_DETECT register to 1 and monitor the PLUG_CONTACT bit status of the USB1_CHRG_DETECT_STAT register. If PLUG_CONTACT is 1, then it indicates that the data pins have make good contacts, otherwise the user should continue to wait until this bit is set.

According to Table 1, it should be noted that the data pin contact detector only works when EN_B=0 and CHK_CHRG_B=1, both bit being of the USB1_CHRG_DETECT register.

43.3.7.3 Charger detector

Once the data pins make contact, the user should enable the charger detector by clearing the CHK_CHRG_B bit that is low-active. Then the user should wait for 40ms and then check the status bit of CHRG_DETECTED in register hw_anadig_usb1_chrg_det_stat. CHRG_DETECTED=1 means that the device is connected to a charger, either a dedicated charger or a charging downstream port (or equivalently called a host charger, or charging host). To further differentiate between a host charger and a dedicated charger, the user is suggested to pull up $USB_n_{\text{DP}}$ signaling a connect event to the host. Then the user should monitor the $USB_n_{\text{DN}}$ line status. If $USB_n_{\text{DN}}=1$, then the charger is a dedicated charger; if $USB_n_{\text{DN}}=0$, then it is a host charger.

43.3.7.4 Charger detection software flow

Upon seeing VBUS, the software should follow the software flow for the charger detection process. The flow chart mentions the "enable the vdd3p0 current limiter". Please refer to the power chapter for details.
USBPHY Charger Detection Software Flow

**Start**

- **Enable the vbbud currer limiter**
  - Set PMU_REG_3P0.ENABLE_ILIMIT = 1'b1
  - and PMU_REG_3P0.ENABLE_LINREG = 1'b1

- **USBn_VBUS_DETECT_STAT**
  - VBUSVALID = 1'b1?

  - **N**
    - **Turn off the charger detector**
      - (set EN_B and CHK_CHRG_B to 1)
      - In register USBn_VBUS_DETECT

  - **Y**
    - **Set CHK_CHRG_B = 1'b1**
    - **And CHK_CONTACT = 1'b1**
    - **Continue normal boot up**

- **USB plug contacted?**
  - **N**
    - **Set CHK_CONTACT = 1'b0**
    - **And CHK_CHRG_B = 1'b0**
    - **Is it a charger?**
      - **N**
        - **Continue boot up**
      - **Y**
        - **Turn off the charger detector**
          - (set EN_B and CHK_CHRG_B to 1)
          - (monitor the PLUG_CONTACT bit)

  - **Y**
    - **Wait for > 40ms**
    - **(monitor the CHRG_DETECTED bit)**

    - **N**
      - **Turn off the charger detector**
        - (set EN_B and CHK_CHRG_B to 1)

    - **Y**
      - **Is it a charger?**
        - **N**
          - **Continue boot up**
        - **Y**
          - **Turn off the charger detector**
            - (set EN_B and CHK_CHRG_B to 1)
          - **Wait for > 40ms**
          - **Initilaize system and USB**
            - (can only draw 100mA current)
          - **Pull DP high to enumerate**
          - **Continue boot up**

  - **Timeout**
    - **VBUS is coming from a dedicated power supply. No USB actions required.**

  - **Continue boot up**

**Figure 43-3. USBPHY Charger Detection Software Flow**
43.3.7.5 Dead Battery Protect

All the descriptions above are based on the assumption that all the power supplies have been on when the device is plugged into a remote host (or charger). However, there are cases when the local battery of the portable device has been so depleted that the system could not be turned on. In such scenarios the user may prefer a method of signaling the external power management unit (PMIC) the existence of the USB charger to draw a current larger than 100mA from the remote host to speed up system boot up or battery charging. The charger detector indeed supports this function.

When we have a fully depleted battery, all the power supplies might be off. Upon insertion of the 5V, the supplies are brought up by the external PMIC and the internal regulators. Due to the 100mA inrush current limit of the USB spec, we cannot draw larger than 100mA current which might be a limit for system boot-up. Since by default, EN_B=0, CHK_CHRG_B=0 and CHK_CONTACT=1, the usb charger detector is automatically enabled without any software operation needed and it can signal the external PMIC the existence of a USB charger through the open-drain output pin USB_OTG_CHD_B. This pin should be pulled up to an external voltage that is acceptable to the PMIC. If this signal is low, then the PMIC can get that the device is connected to a charger. In this case, the PMIC can draw more than 100mA current from the USB.

It should be noted that this function requires cooperation between the chip and the external PMIC. It is suggested that the user consult NXP for such use cases.

</tr>
</thead>
</table>
| 18 RXPWD1PT1 | 0 = Normal operation.  
1 = Power-down the USB full-speed differential receiver.  
Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled. |
| 17 RXPWDENV | 0 = Normal operation.  
1 = Power-down the USB high-speed receiver envelope detector (squelch signal).  
Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled. |
| 16–13 RSVD1 | Reserved. |
| 12 TXPWDV2I | 0 = Normal operation.  
1 = Power-down the USB PHY transmit V-to-I converter and the current mirror.  
Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.  
Note that these circuits are shared with the battery charge circuit. Setting this to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down. |
| 11 TXPWDIBIAS | 0 = Normal operation.  
1 = Power-down the USB PHY current bias block for the transmitter. This bit should be set only when the USB is in suspend mode. This effectively powers down the entire USB transmit path.  
Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled.  
Note that these circuits are shared with the battery charge circuit. Setting this bit to 1 does not power-down these circuits, unless the corresponding bit in the battery charger is also set for power-down. |
| 10 TXPWDFS | 0 = Normal operation.  
1 = Power-down the USB full-speed drivers. This turns off the current starvation sources and puts the drivers into high-impedance output.  
Note that this bit will be auto cleared if there is USB wakeup event while ENAUTOCLR_PHY_PWD bit of USBPHYx_CTRL is enabled. |
| RSVD0 | Reserved. |

## USBPHYx_CTRL field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 SFTRST</td>
<td>Writing a 1 to this bit will soft-reset the USBPHYx_PWD, USBPHYx_TX, USBPHYx_RX, and USBPHYx_CTRL registers. Set to 0 to release the PHY from reset.</td>
</tr>
<tr>
<td>30 CLKGATE</td>
<td>Gate UTMI Clocks. Clear to 0 to run clocks. Set to 1 to gate clocks. Set this to save power while the USB is not actively being used. Configuration state is kept while the clock is gated. Note this bit can be auto-cleared if there is any wakeup event when USB is suspended while ENAUTOCLR_CLKGATE bit of USBPHYx_CTRL is enabled.</td>
</tr>
<tr>
<td>29 UTMI_SUSPENDM</td>
<td>Used by the PHY to indicate a powered-down state. If all the power-down bits in the USBPHYx_PWD are enabled, UTMI_SUSPENDM will be 0, otherwise 1. UTMI_SUSPENDM is negative logic, as required by the UTMI specification.</td>
</tr>
<tr>
<td>28 HOST_FORCE_LS_SE0</td>
<td>Forces the next FS packet that is transmitted to have an EOP with LS timing. This bit is used in host mode for the resume sequence. After the packet is transferred, this bit is cleared. The design can use this function to force the LS SE0 or use the USBPHYx_CTRL_UTMI_SUSPENDM to trigger this event when leaving suspend. This bit is used in conjunction with USBPHYx_DEBUG_HOST_RESUME_DEBUG.</td>
</tr>
<tr>
<td>27 OTG_ID_VALUE</td>
<td>Almost same as OTGID_STATUS in USBPHYx_STATUS Register. The only difference is that OTG_ID_VALUE has debounce logic to filter the glitches on ID Pad.</td>
</tr>
<tr>
<td>26–25 RSVD1</td>
<td>Reserved.</td>
</tr>
<tr>
<td>24 FSDL RST EN</td>
<td>Enables the feature to reset the FSDLL lock detection logic at the end of each TX packet.</td>
</tr>
<tr>
<td>23 ENVBUSCHG_WKUP</td>
<td>Enables the feature to wakeup USB if VBUS is toggled when USB is suspended.</td>
</tr>
<tr>
<td>22 ENIDCHG_WKUP</td>
<td>Enables the feature to wakeup USB if ID is toggled when USB is suspended.</td>
</tr>
<tr>
<td>21 ENDPDMCHG_WKUP</td>
<td>Enables the feature to wakeup USB if DP/DM is toggled when USB is suspended. This bit is enabled by default.</td>
</tr>
<tr>
<td>20 ENAUTOCLR_PHY_PWD</td>
<td>Enables the feature to auto-clear the PWD register bits in USBPHYx_PWD if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.</td>
</tr>
<tr>
<td>19 ENAUTOCLR_CLKGATE</td>
<td>Enables the feature to auto-clear the CLKGATE bit if there is wakeup event while USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.</td>
</tr>
<tr>
<td>18 ENAUTO_PWRON_PLL</td>
<td>Enables the feature to auto-enable the POWER bit of HW_CLKCTRL_PLLxCTRL0 if there is wakeup event if USB is suspended. This should be enabled if needs to support auto wakeup without S/W's interaction.</td>
</tr>
<tr>
<td>17 WAKEUP_IRQ</td>
<td>Indicates that there is a wakeup event. Reset this bit by writing a 1 to the clear address space and not by a general write.</td>
</tr>
<tr>
<td>16 ENIRQWAKEUP</td>
<td>Enables interrupt for the wakeup events.</td>
</tr>
<tr>
<td>15 ENUTMILEVEL3</td>
<td>Enables UTMI+ Level3. This should be enabled if needs to support external FS Hub with LS device connected</td>
</tr>
<tr>
<td>14 ENUTMILEVEL2</td>
<td>Enables UTMI+ Level2. This should be enabled if needs to support LS device</td>
</tr>
<tr>
<td>13 DATA_ON_LRADC</td>
<td>Enables the LRADC to monitor USB_DP and USB_DM. This is for use in non-USB modes only.</td>
</tr>
<tr>
<td>12 DEVPLUGIN_IRQ</td>
<td>Indicates that the device is connected. Reset this bit by writing a 1 to the clear address space and not by a general write.</td>
</tr>
</tbody>
</table>

Table continues on the next page...
### USBPHYx_CTRLn field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>11 ENIRQDEVPLUGIN</td>
<td>Enables interrupt for the detection of connectivity to the USB line.</td>
</tr>
<tr>
<td>10 RESUME_IRQ</td>
<td>Indicates that the host is sending a wake-up after suspend. This bit is also set on a reset during suspend. Use this bit to wake up from suspend for either the resume or the reset case. Reset this bit by writing a 1 to the clear address space and not by a general write.</td>
</tr>
<tr>
<td>9 ENIRQRESUMEDETECT</td>
<td>Enables interrupt for detection of a non-J state on the USB line. This should only be enabled after the device has entered suspend mode.</td>
</tr>
<tr>
<td>8 RESUMEIRQSTICKY</td>
<td>Set to 1 will make RESUME_IRQ bit a sticky bit until software clear it. Set to 0, RESUME_IRQ only set during the wake-up period.</td>
</tr>
<tr>
<td>7 ENOTGIDDETECT</td>
<td>Enables circuit to detect resistance of MiniAB ID pin.</td>
</tr>
<tr>
<td>6 OTG_ID_CHG_IRQ</td>
<td>OTG ID change interrupt. Indicates the value of ID pin changed.</td>
</tr>
<tr>
<td>5 DEVPLUGIN_POLARITY</td>
<td>For device mode, if this bit is cleared to 0, then it trips the interrupt if the device is plugged in. If set to 1, then it trips the interrupt if the device is unplugged.</td>
</tr>
<tr>
<td>4 ENDEVPLUGINDETECT</td>
<td>For device mode, enables 200-KOhm pullups for detecting connectivity to the host.</td>
</tr>
<tr>
<td>3 HOSTDISCONDETECT_IRQ</td>
<td>Indicates that the device has disconnected in high-speed mode. Reset this bit by writing a 1 to the clear address space and not by a general write.</td>
</tr>
<tr>
<td>2 ENIRQHOSTDISCON</td>
<td>Enables interrupt for detection of disconnection to Device when in high-speed host mode. This should be enabled after ENDEVPLUGINDETECT is enabled.</td>
</tr>
<tr>
<td>1 ENHOSTDISCONDETECT</td>
<td>For host mode, enables high-speed disconnect detector. This signal allows the override of enabling the detection that is normally done in the UTMI controller. The UTMI controller enables this circuit whenever the host sends a start-of-frame packet. SW shall set this bit when it found the high-speed device is connected, suggested during bus reset, after found high-speed device in USB_PORTSC1.PSPD). SW shall make sure this bit is not set at the end of resume, otherwise a wrong disconnect status may be detected. Suggest clear it after set USB_PORTSC1.SUSP, set it again after resume is ended(USB_PORTSC1.FPR==0).</td>
</tr>
<tr>
<td>0 ENOTG_ID_CHG_IRQ</td>
<td>Enable OTG_ID_CHG_IRQ.</td>
</tr>
</tbody>
</table>
43.4.5  USB PHY Status Register (USBPHYx_STATUS)

The USB PHY Status Register holds results of IRQ and other detects.

Address: Base address + 40h offset

44.2 Overview

The Flexible Controller Area Network (FLEXCAN) module is a communication controller implementing the CAN protocol according to the CAN 2.0B protocol specification.

The CAN protocol was primarily designed to be used as a vehicle serial data bus meeting the specific requirements of this field: real-time processing, reliable operation in the EMI environment of a vehicle, cost-effectiveness and required bandwidth. The FLEXCAN module is a full implementation of the CAN protocol specification, which supports both standard and extended message frames. 64 Message Buffers are supported by the Flexcan module.
44.2.1 Block Diagram

A general block diagram is shown in the figure below, which describes the main sub-blocks implemented in the FLEXCAN module, including the associated memory for storing Mailboxes, Rx Global Mask Registers, Rx Individual Mask Registers, Rx FIFO and Rx FIFO ID Filters.

Support for 64 Mailboxes and 6-deep Rx FIFO is provided. The functions of the sub-modules are described in subsequent sections.
Figure 44-1. FLEXCAN Block Diagram
44.2.2 FLEXCAN Module Features

The FLEXCAN module includes these distinctive legacy features:

- Version 2.0B
  - Standard data and remote frames
  - Extended data and remote frames
  - Zero to eight bytes data length
  - Programmable bit rate up to 1 Mb/sec
  - Content-related addressing
- Flexible Mailboxes of eight bytes data length
- Each Mailbox is configurable as Rx or Tx, all supporting standard and extended messages
- Individual Rx Mask Registers per Mailbox
- Full featured Rx FIFO with storage capacity for 6 frames and internal pointer handling
- Transmission abort capability
- Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard or 512 partial (8 bits) IDs, with up to 32 individual masking capability
- 100% backwards compatibility with previous FLEXCAN version
- Unused structures space can be used as general purpose RAM space
- Listen only mode capability
- Programmable loop-back mode supporting self-test operation
- Programmable transmission priority scheme: lowest ID, lowest buffer number or highest priority
- Time Stamp based on 16-bit free-running timer
- Global network time, synchronized by a specific message
- Maskable interrupts independent of the transmission medium (an external transceiver is assumed)
- Short latency time due to an arbitration scheme for high-priority messages
- Low power modes, with programmable wake up on bus activity
- Configurable Glitch filter width to filter the noise on CAN bus when waking up
- Remote request frames may be handled automatically or by software.
- ID filter configuration in Normal Mode
- CAN bit time settings and configuration bits can only be written in Freeze Mode
- Tx mailbox status (Lowest priority buffer or empty buffer)
- SYNC bit status to inform that the module is synchronous with CAN bus
- CRC status for transmitted message
- Selectable priority between Mailboxes and Rx FIFO during matching process
44.2.3 Modes of Operation

The FLEXCAN module has four functional modes: Normal Mode (User and Supervisor), Freeze Mode, Listen-Only Mode and Loop-Back Mode. There are also two low power modes: Disable Mode and Stop Mode.

• Normal Mode (User or Supervisor):

In Normal Mode, the module operates receiving and/or transmitting message frames, errors are handled normally and all the CAN Protocol functions are enabled. User and Supervisor Modes differ in the access to some restricted control registers.

• Freeze Mode:

It is enabled when the FRZ bit in the MCR Register is asserted. If enabled, Freeze Mode is entered when the HALT bit in MCR is set or when Debug Mode is requested at MCU level and the FRZ_ACK bit in the MCR Register is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze Mode for more information.

• Listen-Only Mode:

The module enters this mode when the LOM bit in the Control Register is asserted. In this mode, transmission is disabled, all error counters are frozen and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FLEXCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

• Loop-Back Mode:

The module enters this mode when the LPB bit in the Control Register is asserted. In this mode, FLEXCAN performs an internal loop back that can be used for self test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The FLEXCAN_RX input pin is ignored and the FLEXCAN_TX output goes to the recessive state (logic '1'). FLEXCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FLEXCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

• Module Disable Mode:
This low power mode is entered when the MDIS bit in the MCR Register is asserted and
the LPM_ACK is asserted by the FlexCAN. When disabled, the module requests to
disable the clocks to the CAN Protocol Engine and Controller Host Interface sub-
modules. Exit from this mode is done by negating the MDIS bit in the MCR Register. See
Module Disable Mode for more information.

- Stop Mode:

This low power mode is entered when Stop Mode is requested at Arm level and the
LPM_ACK bit in the MCR Register is asserted by the FlexCAN. When in Stop Mode,
the module puts itself in an inactive state and then informs the Arm that the clocks can be
shut down globally. Exit from this mode happens when the Stop Mode request is
removed or when activity is detected on the CAN bus and the Self Wake Up mechanism
is enabled. See Stop Mode for more information.

44.3 External Signals

The FLEXCAN module has two I/O signals.

44.5 Message Buffer Structure

Message Buffer Address: Base + 0x0080-0x047C.

The Message Buffer structure used by the FLEXCAN module is represented in the following table.

Both Extended and Standard Frames (29-bit Identifier and 11-bit Identifier, respectively) used in the CAN specification are represented.

Each individual Message buffer is formed by 16 bytes.

<table>
<thead>

</tr>
</tbody>
</table>

1. SRV: Serviced MB. MB was read and unlocked by reading TIMER or other MB.
2. A frame is considered successful reception after the frame to be moved to MB (move-in process). Refer to Move-in for details
3. Remote Request Stored bit from CTRL2 register. Refer to CTRL2 for details.
4. Code 4'b1010 is not considered as a Tx and a MB with this code should not to be aborted.
5. Note that for Tx MBs, the BUSY bit should be ignored upon read, except when AEN bit is set in the MCR register. If this bit is asserted, the corresponding MB does not participate in the matching process.

The remote response frame will be transmitted unconditionally once and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. Refer to Matching Process and Arbitration process for details.</td>
</tr>
</tbody>
</table>

SRR - Substitute Remote Request

Fixed recessive bit, used only in extended format. It must be set to '1' by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FLEXCAN receives this bit as dominant, then it is interpreted as arbitration loss.

1= Recessive value is compulsory for transmission in Extended Format frames
0= Dominant is not a valid value for transmission in Extended Format frames

IDE - ID Extended Bit

This bit identifies whether the frame format is standard or extended. It is also used as part of the reception filter.

1= Frame format is extended
0= Frame format is standard

RTR - Remote Transmission Request
This bit affects the behavior of Remote Frames and is part of the reception filter. Refer to the tables above and RRS bit in **Control 2 Register (FLEXCAN_CTRL2)** for additional details.

If FLEXCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FLEXCAN module treats it as bit error. If the value received matches the value transmitted, it is considered as a successful bit transmission.

1= Indicates the current MB has a Remote Frame to be transmitted if MB is Tx. If the MB is Rx then incoming Remote Request Frames may be stored.

0= Indicates the current MB has a Data Frame to be transmitted. In Rx MB it may be considered in matching processes.

**DLC - Length of Data in Bytes**

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x08 through 0x0F of the MB space (see the first table above). In reception, this field is written by the FLEXCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the Arm and corresponds to the DLC field value of the frame to be transmitted. When RTR=1, the Frame to be transmitted is a Remote Frame and does not include the data field, regardless of the Length field. The DLC field indicates which DATA BYTES are valid as shown in the table below.

**TIME STAMP - Free-Running Counter Time Stamp**

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

**PRIO - Local priority**

This 3-bit field is only used when MCR[LPRIO_EN] bit is asserted and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See ** Arbitration process**.

**ID - Frame Identifier**

In Standard Frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In Extended Frame format, all bits are used for frame identification in both receive and transmit cases.

**DATA BYTE 0-7 - Data Field**

Up to eight bytes can be used for a data frame.
For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE (n) is valid only if \( n \) is less than DLC as shown in the table below.

For Tx frames, the CPU prepares the data field to be transmitted within the frame.

### 44.6 Rx FIFO Structure

When the MCR[RFEN] bit is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0 to 5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a Message Buffer. This output contains the oldest message received and not read yet. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, that starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6 up to 37) depending on the CTRL2[RFFN] field setting, contains the ID Filter Table (configurable from 8 to 128 memory positions) that specifies filtering criteria for accepting frames into the FIFO. Table 44-8 shows the Rx FIFO data structure.

Each ID Filter Table Element occupies an entire 32-bit word and can be compounded by one, two or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. Table 44-9, Table 44-10 and Table 44-11 show the IDAF indexation. Table 44-12 show the three different formats that the IDAF can assume, depending on the MCR[IDAM] field setting. Note that all elements of the table must have the same format. See Rx FIFO for more information.

Out of reset, the ID Filter Table flexible memory area defaults to 0xE0 and only extends to 0xFC, which corresponds to MBs 6 to 7 for RFFN=0.
Table 44-8. Rx FIFO Structure

|   | 31 | 30 | 29 | 28 | 27 | 26 | 25 | 24 | 23 | 22 | 21 | 20 | 19 | 18 | 17 | 16 | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |

RTR - Remote Frame

This bit specifies whether Remote Request Frames are accepted into the FIFO if they match the target ID in Formats A and B. If Format C is chosen the acceptance does not depend on whether the frame is a Remote Request Frame or not.

1= Remote Frames can be accepted and data frames are rejected
0= Remote Frames are rejected and data frames can be accepted

IDE - Extended Frame

Specifies if either Extended or Standard Format frames are accepted into the FIFO if they match the target ID in Formats A and B. If Format C is chosen the acceptance does not depend on whether the frame is of the Extended or Standard Format.

1= Extended frames can be accepted and standard frames are rejected
0= Extended frames are rejected and standard frames can be accepted
RXIDA - Rx Frame Identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the Standard Format (IDAF's or incoming frame's IDE bit is negated), only the 11 most significant bits (29 to 19) are used for frame identification. In the Extended Format (both IDAF's and incoming frame's IDE are asserted), all bits are used.

RXIDB_0, RXIDB_1 - Rx Frame Identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the Standard Format (IDAF's or incoming frame's IDE bit is negated), the 11 most significant bits (29 to 19 and 13 to 3) are used for frame identification. In the Extended Format (both IDAF's and incoming frame's IDE are asserted), all 14 bits of the field are compared with the 14 most significant bits of the Identifier of the incoming frame. The 15 least significant bits of the Identifier of an incoming Extended Format frame do not affect the acceptance.

RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3 - Rx Frame Identifier (Format C)

Specifies an ID to be used as acceptance criteria for the FIFO. In both Standard Format and Extended Format, all 8 bits of the field are compared to the 8 most significant bits of the Identifier of the incoming frame. The 3 least significant bits of the Identifier of an incoming Standard Format frame and the 21 least significant bits of the Identifier of an incoming Extended Format frame do not affect the acceptance.

### 44.7 Functional Description

This section provides a complete functional description of the block.

#### 44.7.1 Functional Overview

The FLEXCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system consists of a set of 64 Message Buffers (MB) that store configuration and control data, time stamp, message ID and data (see Message Buffer Structure). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID Filter Table elements. Simultaneous reception through FIFO and mailbox is supported. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID. A masking scheme makes it possible to match the ID programmed on the MB with a range of Identifiers on received frames.
CAN frames. For transmission, an *arbitration* algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A Message Buffer is said to be "active" at a given time if it can participate in both the Matching and Arbitration processes. An Rx MB with a 0b0000 code is inactive (refer to Table 44-5). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (refer to Table 44-6).

### 44.7.2 Transmit Process

In order to transmit a CAN frame, the CPU must prepare a Message Buffer for transmission by executing the procedure found here.

1. Check if the respective interruption bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abortion of the transmission. Wait for the corresponding IFLAG to be asserted by polling the IFLAG register or by the interrupt request if enabled by the respective IMASK. Then read back the CODE field to check if the transmission was aborted or transmitted (see Transmission Abort Mechanism). If backwards compatibility is desired (MCR[AEN] bit negated), just write the INACTIVE code (0b1000) to the CODE field to inactivate the MB but then the pending frame may be transmitted without notification (see Message Buffer Inactivation).
3. Write the ID word.
4. Write the data bytes.
5. Write the DLC, Control and Code fields of the Control and Status word to activate the MB.

Once the MB is activated, it will participate into the arbitration process and eventually be transmitted according to its priority.

At the end of the successful transmission, the value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the MB's Time Stamp field, the CODE field in the Control and Status word is updated, the CRC Register is updated, a status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit. The new CODE field after transmission depends on the code that was used to activate the MB in step four (see Table 44-5 and Table 44-6 in Message Buffer Structure).
When the Abort feature is enabled (MCR[AEN] bit is asserted), after the Interrupt Flag is asserted for a Mailbox configured as transmit buffer, the Mailbox is blocked, therefore the CPU is not able to update it until it negates the Interrupt Flag. It means that the CPU must clear the corresponding IFLAG before starting to prepare this MB for a new transmission or reception.

### 44.7.3 Arbitration process

The arbitration process scans the Mailboxes searching the Tx one that holds the message to be sent in the next opportunity. This Mailbox is called the *arbitration winner*.

The scan starts from the lowest Mailbox number and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the CTRL2[TASD] field value. See Control 2 Register (FLEXCAN_CTRL2) for details.
- During the error delimiter field of the CAN frame
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When Arm write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and Arm writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state
- Upon leaving Freeze Mode or Low Power Mode

If the arbitration process does not manage to evaluate all Mailboxes before the CAN bus has reached the first bit of the Intermission field the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.

The arbitration process selects the winner among the active Tx Mailboxes at the end of the scan according to both CTRL1[LBUF] and MCR[LPRIO_EN] bits settings.

#### 44.7.3.1 Lowest Mailbox number first

If CTRL1[LBUF] bit is asserted the first (lowest number) active Tx Mailbox found is the arbitration winner. MCR[LPRIO_EN] bit has no effect when CTRL1[LBUF] is asserted.
44.7.3.2 Highest Mailbox priority first

If CTRL1[LBUF] bit is negated then the arbitration process searches the active Tx Mailbox with the highest priority, and this Mailbox would have a higher probability to win the arbitration on CAN bus.

The sequence of bits considered for this arbitration is called the *arbitration value* of the Mailbox. The highest priority Tx Mailbox is the one that has the least arbitration value among all Tx Mailboxes.

If two or more Mailboxes have equivalent arbitration values the lowest Mailbox number is the arbitration winner.

The composition of the arbitration value depends on MCR[LPRIO_EN] bit setting.

44.7.3.2.1 Local Priority disabled

If MCR[LPRIO_EN] bit is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see Table 44-13) in such a way that the Local Priority is disabled.

<table>
<thead>
<tr>
<th>Format</th>
<th>Mailbox Arbitration Value (32 bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard (IDE = 0)</td>
<td>Standard ID (11 bits) RTR (1 bit) IDE (1 bit) - (18 bits)</td>
</tr>
<tr>
<td>Extended (IDE = 1)</td>
<td>Extended ID[28:18] (11 bits) SRR (1 bit) IDE (1 bit) Extended ID[17:0] (18 bits)</td>
</tr>
</tbody>
</table>

44.7.3.2.2 Local Priority enabled

If Local Priority is desired MCR[LPRIO_EN] must be asserted.

In this case the Mailbox PRIO field is included at the very left of the arbitration value (see the table below).

<table>
<thead>
<tr>
<th>Format</th>
<th>Mailbox Arbitration Value (35 bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard (IDE = 0)</td>
<td>PRIO (3 bits) Standard ID (11 bits) RTR (1 bit) IDE (1 bit) - (18 bits)</td>
</tr>
<tr>
<td>Extended (IDE = 1)</td>
<td>PRIO (3 bits) Extended ID[28:18] (11 bits) SRR (1 bit) IDE (1 bit) Extended ID[17:0] (18 bits)</td>
</tr>
</tbody>
</table>

Table 44-13. Composition of the arbitration value when Local Priority is disabled

Table 44-14. Composition of the arbitration value when Local Priority is enabled
As the PRIO field is the most significant part of the arbitration value Mailboxes with low PRIO values have higher priority than Mailboxes with high PRIO values regardless the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

Once the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called "move-out" and after it is done, write access to the corresponding MB is blocked (if the AEN bit in MCR is asserted). The write access is released in the following events:

- After the MB is transmitted
- FlexCAN enters in Freeze Mode or Bus Off
- FlexCAN loses the bus arbitration or there is an error during the transmission

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules. FlexCAN transmits up to eight data bytes, even if the DLC (Data Length Code) field value is greater than that.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. Arbitration start point depends on instantiation parameters NUMBER_OF_MB and TASD. Additionally, TASD value may be changed (see Control 2 Register (FLEXCAN_CTRL2)) to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT=124 to 128. Arbitration start point depends on instantiation parameters NUMBER_OF_MB and TASD. Additionally, TASD value may be changed (see Control 2 Register (FLEXCAN_CTRL2)) to optimize the arbitration start point.
- During C/S write by CPU in Bus Idle. First C/S write starts arbitration process and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after arbitration process has finished, then TX arbitration machine begins a new arbitration process.
- Arbitration winner deactivation during a valid arbitration window.
- Upon Leave Freeze Mode. If there is a re-synchronization during WaitForBusIdle arbitration process is restarted.

Arbitration process stops in the following situation:

- All Mailboxes were scanned.
- A Tx active Mailbox is found in case of Lowest Buffer feature enabled.
- Arbitration winner inactivation or abort during any arbitration process.
• There was not enough time to finish Tx arbitration process. For instance, a deactivation was performed near the end of frame). In this case arbitration process is pending.
• Error or Overload flag in the bus.
• Low Power or Freeze Mode request in Idle state

Arbitration is considered pending as described below:

• It was not possible to finish arbitration process in time.
• C/S write during arbitration if write is performed in a MB which number is lower than the Tx arbitration pointer.
• Any C/S write if there is no Tx Arbitration process in progress.
• Rx Match has just updated a Rx Code to Tx Code.
• Entering Bus off state.

C/S write during arbitration has the following effect:

• If C/S write is performed in the arbitration winner, a new process is restarted immediately.
• C/S write during arbitration if write is performed in a MB which number is higher than the Tx arbitration pointer.

44.7.4 Receive Process

To be able to receive CAN frames into a Mailbox, the CPU must prepare it for reception by executing the steps listed here.

1. If the Mailbox is active (either Tx or Rx) inactivate the Mailbox (see Message Buffer Inactivation), preferably with a safe inactivation (see Transmission Abort Mechanism);
2. Write the ID word;
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the Mailbox.

Once the Mailbox is activated in the third step, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the Mailbox is updated by the move-in process (see Move-in) as follows:

1. The received Data field (8 bytes at most) is stored;
2. The received Identifier field is stored;
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the Mailbox Time Stamp field;
4. The received SRR, IDE, RTR and DLC fields are stored;
5. The CODE field in the Control and Status word is updated. (see Table 44-5 and Table 44-6 in Section Message Buffer Structure)

6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for the CPU servicing (read) the frame received in a Mailbox is using the following procedure:

1. Read the Control and Status word of that Mailbox;
2. Check if the BUSY bit is deasserted, indicating that the Mailbox is locked. Repeat step 1) while it is asserted. See Message Buffer Lock Mechanism;
3. Read the contents of the Mailbox. Once Mailbox is locked now, its contents won't be modified by FlexCAN Move-in processes. See Move-in;
4. Acknowledge the proper flag at IFLAG registers;
5. Read the Free Running Timer. It is optional but recommended to unlock Mailbox as soon as possible and make it available for reception.

The CPU should synchronize to frame reception by the status flag bit for the specific Mailbox in one of the IFLAG Registers and not by the CODE field of that Mailbox. Polling the CODE field does not work because once a frame was received and the CPU services the Mailbox (by reading the C/S word followed by unlocking the Mailbox), the CODE field will not return to EMPTY. It will remain FULL. If the CPU tries to workaround this behavior by writing to the C/S word to force an EMPTY code after reading the Mailbox without a prior safe inactivation, a newly received message matching the filter of that Mailbox may be lost.

In summary: never do polling by reading directly the C/S word of the Mailboxes. Instead, read the IFLAG registers.

Note that the received frame's Identifier field is always stored in the matching Mailbox, thus the contents of the ID field in a Mailbox may change if the match was due to masking. Note also that FlexCAN does receive frames transmitted by itself if there exists a matching Rx Mailbox, provided the MCR[SRX_DIS] bit is not asserted. If MCR[SRX_DIS] bit is asserted, FlexCAN will not store messages transmitted by itself in any MB, even if it contains a matching MB, and no interrupt flag or interrupt signal will be generated due to the frame reception.

To be able to receive CAN messages through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze Mode(see Rx FIFO). Upon receiving the Frames Available in Rx FIFO interrupt(see Interrupt Masks 1 Register (FLEXCAN.IMASK1), bit IFLAG[BUF5I] - Frames available in Rx FIFO), the CPU should service the received frame using the following procedure:
1. Read the Control and Status word (optional - needed only if a mask was used for IDE and RTR bits);
2. Read the ID field (optional - needed only if a mask was used);
3. Read the Data field;
4. Read the RXFIR register (optional);
5. Clear the Frames Available in Rx FIFO interrupt by writing 1 to IFLAG[BUF5I] bit (mandatory - releases the MB and allows the CPU to read the next Rx FIFO entry)

### 44.7.5 Matching Process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between Mailboxes and FIFO filters. In any case, the matching starts from the lowest number Message Buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm will always look for a matching MB outside the FIFO region.

As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- if the received frame is a remote frame, the start point is the CRC field of the frame;
- if the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame;
- if the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame;

If a matching ID is found in the FIFO table or in one of the Mailboxes, the contents of the SMB will be transferred to the FIFO or to the matched Mailbox by the move-in process. If any CAN protocol error is detected then no match results will be transferred to the FIFO or to the matched Mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and active Rx Mailboxes (CODE is EMPTY, FULL, OVERRUN or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The SMB has the same structure of a Mailbox. The reception structures (Rx FIFO or Mailboxes) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures and depends on conditions described ahead. Refer to the following table for details.
Table 44-15. Matching architecture

</tr>
</tbody>
</table>

1. For Mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). In case of SMB[IDE] to be negated, the ID is only 11 bits (ID Standard). Please, refer to Message Buffer Structure for ID details. For FIFO structure, the ID depends on IDAM. Please, refer to Rx FIFO Structure for IDAM details.
2. cmp: Compares the SMB contents with the MB contents regardless the masks.
3. no_cmp: The SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- the CODE field of the Mailbox is EMPTY;
- the CODE field of the Mailbox is either FULL or OVERR and it has already been serviced (the C/S word was read by the Arm and unlocked as described in Message Buffer Lock Mechanism);
- the CODE field of the Mailbox is either FULL or OVERR and an inactivation is performed. (see Message Buffer Inactivation)
- the Rx FIFO is not full.

The scan order for Mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for Mailboxes is affected by the MCR[IRMQ] bit. If it is negated the matching winner is the first matched Mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched Mailbox;
2. the last non free-to-receive matched Mailbox.
It is possible to select the priority of scan between Mailboxes and Rx FIFO by the CTRL2[MRP] bit.

If the selected priority is Rx FIFO first:

- if the Rx FIFO is a matched structure and is free-to-receive then the Rx FIFO is the matching winner regardless of the scan for Mailboxes;
- otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among Mailboxes as described above.

If the selected priority is Mailboxes first:

- if a free-to-receive matched Mailbox is found, it is the matching winner regardless the scan for Rx FIFO;
- if no matched Mailbox is found, then the matching winner is searched in the scan for the Rx FIFO;
- if both conditions above are not satisfied and a non free-to-receive matched Mailbox is found then the matching winner determination is conditioned by the MCR[IRMQ] bit:
  - if MCR[IRMQ] bit is negated the matching winner is the first matched Mailbox;
  - if MCR[IRMQ] bit is asserted the matching winner is the Rx FIFO if it is a free-to-receive matched structure, otherwise the matching winner is the last non free-to-receive matched Mailbox.

Please, refer to the table below for a summary of matching possibilities.

If a non-safe Mailbox inactivation (see Message Buffer Inactivation) occurs during matching process and the Mailbox inactivated is the temporary matching winner then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted, it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled and there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm will find the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm will find MB number 2 again, but it is not "free-to-receive", so it will keep looking and find MB number 5 and store the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

1. It is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non-free-to-receive).
3. It is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "NotFull" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.
The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for Arm to service the MBs. By programming more than one MB with the same ID, received messages will be queued into the MBs. Arm can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID Acceptance Masks. FlexCAN supports individual masking per MB. Please refer to Rx Mailboxes Global Mask Register (FLEXCAN_RXMGMASK). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is "don't care". Please note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed while the module is in Freeze Mode, otherwise they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RGXMASK, RX14MASK, RX15MASK and RXFGMASK) for backward compatibility. This alternate masking scheme is enabled when the IRMQ bit in the MCR Register is negated.

### 44.7.6 Move Process

There are two types of move process, namely move-in and move-out.

#### 44.7.6.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to a Rx Mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching Process) and all of the following conditions are true:

- the CAN bus has reached or let past either:
  - the second bit of Intermission field next to the frame that carried the message that is in the Rx SMB;
  - the first bit of an overload frame next to the frame that carried the message that is in the Rx SMB;
- there is no ongoing matching process;
• the destination Mailbox is not locked by Arm;
• there is no ongoing move-in process from another Rx SMB. If more than one move-in processes are to be started at the same time both are performed and the newest substitutes the oldest.

The term *pending move-in* is used throughout the document and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

• the destination Mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished;
• there is a previous pending move-in to the same destination Mailbox.
• the Rx SMB is receiving a frame transmitted by the FlexCAN itself and the self-reception is disabled;
• any CAN protocol error is detected.

Note that the pending move-in is not cancelled if the module enters in Freeze or Low Power Mode. It only stays on hold waiting for exiting Low Power Mode and to be unlocked. If an MB is unlocked during Freeze Mode, the move-in happens immediately.

The move-in process consists of the following steps:

1. if the message is destined to the Rx FIFO, push IDHIT into the RXFIR FIFO;
2. reads the words DATA0-3 and DATA4-7 from the Rx SMB;
3. writes it in the words DATA0-3 and DATA4-7 of the Rx Mailbox;
4. reads the words Control/Status and ID from the Rx SMB;
5. writes it in the words Control/Status and ID of the Rx Mailbox, updating the CODE field according to Table 44-5.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination Mailbox (see Message Buffer Inactivation) and in this case the Mailbox may be left partially updated, thus incoherent. The exception is if the move-in destination is an Rx FIFO Message Buffer, then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination Message Buffer is asserted while the move-in is being performed in such a way that Arm beware that the Message Buffer content is temporarily incoherent.
44.7.6.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- the first bit of Intermission field;
- during Bus off field when TX Error Counter is in the 124 to 128 range;
- during BusIdle field;
- during Wait For Bus Idle field.

The move-out process is not atomic. Only Arm has priority to access the memory concurrently out of BusIdle state. In BusIdle, the move-out has the lowest priority to the concurrent memory accesses.

44.7.7 Data Coherence

In order to maintain data coherency and FlexCAN proper operation, the Arm must obey the rules described in the Transmit Process and Receive Process.

Any form of Arm accessing an MB structure within FlexCAN other than those specified may cause FlexCAN to behave in an unpredictable way.

44.7.7.1 Transmission Abort Mechanism

The abort mechanism provides a safe way to request the abortion of a pending transmission. A feedback mechanism is provided to inform Arm if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

In order to abort a transmission, Arm must write a specific abort code (0b1001) to the CODE field of the Control and Status word. The active MBs configured as transmission must be aborted first and then they may be updated. If the abort code is written to a Mailbox that is currently being transmitted, or to a Mailbox that was already loaded into the SMB for transmission, the write operation is blocked and the MB is kept active, but the abort request is captured and kept pending until one of the following conditions are satisfied:

- The module loses the bus arbitration
- There is an error during the transmission
- The module is put into Freeze Mode
- The module enters in BusOff state
- There is an overload frame
If none of conditions above are reached, the MB is transmitted correctly, the interrupt flag is set in the IFLAG register and an interrupt to the Arm is generated (if enabled). The abort request is automatically cleared when the interrupt flag is set. In the other hand, if one of the above conditions is reached, the frame is not transmitted, therefore the abort code is written into the CODE field, the interrupt flag is set in the IFLAG and an interrupt is (optionally) generated to Arm.

If Arm writes the ABORT code before the transmission begins internally, then the write operation is not blocked, therefore the MB is updated and the interrupt flag is set. In this way Arm just needs to read the abort code to make sure the active MB was safely inactivated. Although the AEN bit is asserted and Arm wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is only aborted when the abort request is captured and kept pending until one of the previous conditions are satisfied.

The abort procedure can be summarized as follows:

1. Arm checks the corresponding IFLAG and clears it, if asserted.
2. Arm writes 0b1001 into the CODE field of the C/S word.
3. Arm waits for the corresponding IFLAG indicating that the frame was either transmitted or aborted.
4. Arm reads the CODE field to check if the frame was either transmitted (CODE=0b1000) or aborted (CODE=0b1001).
5. It is necessary to clear the corresponding IFLAG in order to allow the MB to be reconfigured.

44.7.7.2 Message Buffer Inactivation

Inactivation is a mechanism provided to protect the Mailbox against updates by the FlexCAN internal processes, thus allowing Arm to rely on Mailbox data coherence after having updated it, even in Normal Mode.

If a Mailbox is inactivated it does not participate neither in the arbitration nor in the matching process until it is reactivated. See Transmit Process and Receive Process for more detailed instruction on how to inactivate and reactivate a Mailbox.

In order to inactivate a Mailbox Arm must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

As the user is not able to synchronize the CODE field update with the FlexCAN internal processes an inactivation can lead to undesirable results:
• a frame in the bus that matches the filtering of the inactivated Rx Mailbox may be lost without notice, even if there are other Mailboxes with the same filter;
• a frame containing the message within the inactivated Tx Mailbox may be transmitted without notice.

In order to eliminate such risk and perform a safe inactivation Arm must use the following mechanism along with the inactivation itself:

• for Tx Mailboxes, the Transmission Abort (see Transmission Abort Mechanism);

The inactivation automatically unlocks the Mailbox (see Message Buffer Lock Mechanism).

Message Buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on FIFO region by FlexCAN. Arm must keep the data coherence into FIFO region when RFEN is asserted.

### 44.7.7.3 Message Buffer Lock Mechanism

Besides MB inactivation, FlexCAN has another data coherence mechanism for the receive process. When Arm reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that Arm wants to read the whole MB in an atomic operation, and thus it sets an internal lock flag for that MB. The lock is released when Arm reads the Free Running Timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code or when Arm writes into C/S word from locked MB. The MB locking is done to prevent a new frame to be written into the MB while Arm is reading it.

The locking mechanism only applies to Rx MBs that are not part of FIFO and have a code different than INACTIVE (0b0000) or EMPTY\(^1\) (0b0100). Also, Tx MBs can not be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the Arm decides to read MB number 5 and at the same time another message with the same ID is arriving. When Arm reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no "free-to-receive" MBs, so it decides to override MB number 5. However, this MB is locked, so the new message can not be written there. It will remain in the SMB waiting for the MB to be unlocked, and only then will be written to the MB. If the MB is not unlocked in time and yet another

---

\(^1\) In previous FlexCAN versions, reading the C/S word locks the MB even if it is EMPTY. This behavior is maintained when the IRMQ bit is negated.
new message with the same ID arrives, then the new message overwrites the one on the SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved-in from the SMB to the MB, the BUSY bit on the CODE field is asserted. If Arm reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

Inactivation takes precedence over locking. If Arm inactivates a locked Rx Mailbox, then its lock status is negated and the Mailbox is marked as invalid for the current matching round. Any pending message on the SMB will not be transferred anymore to the Mailbox. An MB is unlocked when Arm reads the Free Running Timer Register (see Free Running Timer Register (FLEXCAN_TIMER)), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during any of the low power modes (see in Modes of Operation specific information on Module Disable or Stop modes) and it will take place only when the module resumes to Normal or Freeze modes.

### 44.7.8 Rx FIFO

The receive-only FIFO is enabled by asserting the RFEN bit in the MCR.

The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature. The FIFO is 6-message deep, therefore when the FIFO is enabled, the memory region occupied by the first 6 Message Buffers is reserved for use of the FIFO engine (see Rx FIFO Structure). Arm can read the received messages sequentially, in the order they were received, by repeatedly reading a Message Buffer structure at the output of the FIFO.

The IFLAG[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, Arm can read the message (accessing the output of the FIFO as a Message Buffer) and the RXFIR register and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and update the RXFIR with the attributes of that message, reissuing the interrupt to Arm. Otherwise, the flag remains negated. The output of the FIFO is only valid when the IFLAG[BUF5I] is asserted.
The IFLAG[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until Arm clears it.

The IFLAG[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the Arm clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, thus reducing the interrupt servicing work load. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Rx FIFO Structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can be read by accessing the RXFIR register. The RXFIR[IDHIT] field refers to the message at the output of the FIFO and is valid whilst the IFLAG[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to thirty two elements of the ID Filter Table are individually affected by the Individual Mask Registers (RXIMR0 - RXIMR31), according to CTRL2[RFFN] setting (refer to Control 2 Register (FLEXCAN_CTRL2)), allowing very powerful filtering criteria to be defined. If the MCR[IRMQ] bit is negated (or if the RXIMR are not available for the particular MCU), then the FIFO ID Filter Table is affected by RXFGMASK.

44.7.9 CAN Protocol Related Features
44.7.9.1 Remote Frames

Remote frame is a special kind of frame. The user can program a mailbox to be a Remote Request Frame by writing the mailbox as Transmit with the RTR bit set to '1'. After the remote request frame is transmitted successfully, the mailbox becomes a Receive Message Buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on Remote Request Storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]) bits:

- If RRS is negated the frame's ID is compared to the IDs of the Transmit Message Buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame was received and matched a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010 or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.

- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the Arm. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote Request Frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.

44.7.9.2 Overload Frames

FLEXCAN does transmit overload frames due to detection of following conditions on CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

44.7.9.3 Time Stamp

The value of the Free Running Timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of "move-in" in the TIME STAMP field, providing network behavior with respect to time.

Note that the Free Running Timer can be reset upon a specific frame reception, enabling network time synchronization. Refer to TSYN description in Control 1 Register (FLEXCAN_CTRL1).

44.7.9.4 Protocol Timing

The FLEXCAN module supports a variety of means to setup bit timing parameters that are required by the CAN protocol. The Control Register has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2 and RJW. See Control 1 Register (FLEXCAN_CTRL1).

The PRESDIV field controls a prescaler that generates the Serial Clock (Sclock), whose period defines the 'time quantum' used to compose the CAN waveform. A time quantum is the atomic unit of time handled by the CAN engine.

\[ f_{Tq} = \frac{f_{CANCLK}}{\text{(Prescaler value)}} \]

A bit time is subdivided into three segments\(^2\) (reference Table 44-17):

---

\(^2\) For further explanation of the underlying concepts please refer to ISO/DIS 11519-1, Section 10.3. Reference also the Bosch CAN 2.0A/B protocol specification dated September 1991 for bit timing.
• **SYNC_SEG**: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.

• **Time Segment 1**: This segment includes the Propagation Segment and the Phase Segment 1 of the CAN standard. It can be programmed by setting the PROPSEG and the PSEG1 fields of the CTRL Register so that their sum (plus 2) is in the range of 2 to 16 time quanta.

• **Time Segment 2**: This segment represents the Phase Segment 2 of the CAN standard. It can be programmed by setting the PSEG2 field of the CTRL Register (plus 1) to be 2 to 8 time quanta long.

\[
\text{Bit Rate} = \frac{f_{Tq}}{(\text{number of Time Quanta})}
\]

![Diagram of segments within the bit time](image)

**Figure 44-2. Segments within the Bit Time**

Whenever CAN bit is used as a measure of duration (e.g. MCR[FRZ_ACK] and MCR[LPM_ACK] in Module Configuration Register (FLEXCAN_MCR)), the number of peripheral clocks in one CAN bit can be calculated as:

\[
NCCP = \frac{f_{sys} \times [1 + (PSEG1 + 1) + (PSEG2 + 1) + (PROPSEG + 1)] \times (PRESDIV + 1)}{f_{CANCLK}}
\]

where:
NCCP is the number of peripheral clocks in one CAN bit;

$f_{\text{CANCLK}}$ is the Protocol Engine (PE) Clock in Hz;

$f_{\text{SYS}}$ is the frequency of operation of the system (CHI) clock, in Hz;

PSEG1 is the value in CTRL1[PSEG1] field;

PSEG2 is the value in CTRL1[PSEG2] field;

PROPSEG is the value in CTRL1[PROPSEG] field;

PRESDIV is the value in CTRL1[PRESDIV] field.

For example, $180 \text{ CAN bits} = 180 \times \text{NCCP peripheral clock periods}$.

Figure 44-2 gives an overview of the CAN compliant segment settings and the related parameter values.

### 44.7.9.5 Arbitration and Matching Timing

During normal reception and transmission of frames, the matching, arbitration, move-in and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.
When doing matching and arbitration, FlexCAN needs to scan the whole Message Buffer memory during the available time window. In order to have sufficient time to do that, the following requirements must be observed:

- A valid CAN bit timing must be programmed, as indicated in Table 44-18
- The peripheral clock frequency can not be smaller than the oscillator clock frequency, i.e. the PLL can not be programmed to divide down the oscillator clock
- There must be a minimum ratio between the peripheral clock frequency and the CAN bit rate, as specified in the following table.
Table 44-19. Minimum Ratio Between Peripheral Clock Frequency and CAN Bit Rate

<table>
<thead>
<tr>
<th>Number of Message Buffers</th>
<th>RFEN</th>
<th>Minimum Number of Peripheral Clocks per CAN bit</th>
</tr>
</thead>
<tbody>
<tr>
<td>16 and 32</td>
<td>0</td>
<td>16</td>
</tr>
<tr>
<td>64</td>
<td>0</td>
<td>25</td>
</tr>
<tr>
<td>16</td>
<td>1</td>
<td>16</td>
</tr>
<tr>
<td>32</td>
<td>1</td>
<td>17</td>
</tr>
<tr>
<td>64</td>
<td>1</td>
<td>30</td>
</tr>
</tbody>
</table>

A direct consequence of the first requirement is that the minimum number of time quanta per CAN bit must be 8, so the oscillator clock frequency should be at least 8 times the CAN bit rate. The minimum frequency ratio specified in Table 44-19 can be achieved by choosing a high enough peripheral clock frequency when compared to the oscillator clock frequency, or by adjusting one or more of the bit timing parameters (PRESDIV, PROPSEG, PSEG1, PSEG2). As an example, taking the case of 64 MBs, if the oscillator and peripheral clock frequencies are equal and the CAN bit timing is programmed to have 8 time quanta per bit, then the prescaler factor (PRESDIV + 1) should be at least 2. For prescaler factor equal to one and CAN bit timing with 8 time quanta per bit, the ratio between peripheral and oscillator clock frequencies should be at least 2.

44.7.10 Modes of Operation Details

The FlexCAN module has four functional modes (Normal Mode, Freeze Mode, Listen-Only Mode and Loop-Back Mode) and two low power modes (Disable Mode and Stop Mode). See in Modes of Operation an introductory description of all these modes of operation. The following sub-sections bring functional details on Freeze mode and the low power modes.

44.7.10.1 Freeze Mode

This mode is requested by Arm through the assertion of the HALT bit in the MCR Register or when the MCU is put into Debug Mode. In both cases it is also necessary that the FRZ bit is asserted in the MCR Register and the module is not in any of the low power modes (Disable, Stop). The acknowledgement is obtained through the assertion by the FlexCAN of FRZ_ACK bit in the same register. The Arm must only consider the FlexCAN in Freeze Mode when both request and acknowledgement conditions are satisfied.

When Freeze Mode is requested during transmission or reception, FlexCAN does the following:
• Waits to be in either Intermission, Passive Error, Bus Off or Idle state
• Waits for all internal activities like arbitration, matching, move-in and move-out to finish. Pending move-in is not taken in account
• Ignores the FLEXCAN_RX input pin and drives the FLEXCAN_TX pin as recessive
• Stops the prescaler, thus halting all CAN protocol activities
• Grants write access to the Error Counters Register, which is read-only in other modes
• Sets the NOT_RDY and FRZ_ACK bits in MCR

After requesting Freeze Mode, the user must wait for the FRZ_ACK bit to be asserted in MCR before executing any other action, otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory mapped registers are accessible, except for CTRL1[CLK_SRC] bit that can be read but cannot be written.

Exiting Freeze Mode is done in one of the following ways:

• Arm negates the FRZ bit in the MCR Register
• The Arm is removed from Debug Mode and the HALT bit is negated

The FRZ_ACK bit is negated after protocol engine recognizes the negation of freeze request. Once out of Freeze Mode, FlexCAN tries to re-synchronize to the CAN bus by waiting for 11 consecutive recessive bits.

44.7.10.2 Module Disable Mode

This low power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the Arm through the assertion of the MDIS bit in the MCR Register and the acknowledgement is obtained through the assertion by the FlexCAN of the LPM_ACK bit in the same register. The Arm must only consider the FlexCAN in Disable Mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze Mode, it requests to disable the clocks to the PE and CHI sub-modules, sets the LPM_ACK bit and negates the FRZ_ACK bit. The ability to shut down the clocks depends on how FlexCAN is integrated into the MCU. If the module is disabled during transmission or reception, FlexCAN does the following:

• Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive
• Waits for all internal activities like arbitration, matching, move-in and move-out to finish. Pending move-in is not taken in account
• Ignores its FLEXCAN_RX input pin and drives its FLEXCAN_TX pin as recessive
• May shut down the clocks to the PE and CHI sub-modules, depending on how FlexCAN is integrated into the MCU
• Sets the NOT_RDY and LPM_ACK bits in MCR

The Bus Interface Unit continues to operate, enabling the Arm to access memory mapped registers, except the Rx Mailboxes Global Mask Registers, the Rx Buffer 14 Mask Register, the Rx Buffer 15 Mask Register, the Rx FIFO Global Mask Register. The Rx FIFO Information Register, the Message Buffers, the Rx Individual Mask Registers, and the reserved words within RAM may not be accessed when the module is in Disable Mode depending on how FlexCAN RAM is integrated into the Arm. Exiting from this mode is done by negating the MDIS bit by Arm, which make FlexCAN requests to resume the clocks and negates the LPM_ACK bit after CAN protocol engine recognizes the negation of disable mode requested by Arm.

### 44.7.10.3 Stop Mode

This is a system low power mode in which system clocks can be stopped for maximum power savings. To enter stop mode, the CPU should manually assert a global Stop Mode request (see the CAN1_STOP_REQ and CAN2_STOP_REQ bit in the register IOMUXC_GPR4) and check the acknowledgement asserted by the FlexCAN (see the CAN1_STOP_ACK and CAN2_STOP_ACK in the register IOMUXC_GPR4). The CPU must only consider the FlexCAN in Stop Mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop Mode request during Freeze Mode, it sets the LPM_ACK bit, negates the FRZ_ACK bit and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally. If Stop Mode is requested during transmission or reception, FlexCAN does the following:

• Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
• Waits for all internal activities like arbitration, matching, move-in and move-out to finish. Pending move-in is not taken in account
• Ignores its FLEXCAN_RX input pin and drives its FLEXCAN_TX pin as recessive
• Sets the NOT_RDY and LPM_ACK bits in MCR
• Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Exiting Stop Mode is done in one of the following ways:

• Arm resuming the clocks and removing the Stop Mode request
• Arm resuming the clocks and Stop Mode request as a result of the Self Wake mechanism
In the Self Wake mechanism, if the SLF_WAK bit in MCR Register was set at the time FlexCAN entered Stop Mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN sets the WAK_INT bit in the ESR Register and, if enabled by the WAK_MSK bit in MCR, generates a Wake Up interrupt to the Arm. Upon receiving the interrupt, the Arm should resume the clocks and remove the Stop Mode request manually. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the FLEXCAN_RX input line while in Stop Mode. See the WAK_SRC bit in Module Configuration Register (FLEXCAN_MCR). This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments, the glitch filter width can be set in Glitch Filter Width Register (FLEXCAN_GFWR).

44.7.11 Interrupts

The module can generate up to 70 interrupt sources (64 interrupts due to message buffers and 6 interrupts due to Ored interrupts from MBs, Bus Off, Error, Tx Warning, Rx Warning and Wake Up)).

The number of actual sources depends on the configured number of message buffers.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception. Each of the buffers has assigned a flag bit in the IFLAG Registers. The bit is set when the corresponding buffer completes a successful transmission/reception and is cleared when the Arm writes it to '1' (unless another interrupt is generated at the same time).

If the Rx FIFO is enabled (bit RFEN on MCR set), the interrupts corresponding to MBs 0 to 7 have a different behavior. Bit 7 of the IFLAG1 becomes the "FIFO Overflow" flag; bit 6 becomes the FIFO Warning flag, bit 5 becomes the "Frames Available in FIFO flag" and bits 4-0 are unused. See Interrupt Flags 1 Register (FLEXCAN_IFLAG1) for more information.

A combined interrupt for all MBs is also generated by an Or of all the interrupt sources from MBs. This interrupt gets generated when any of the Mailboxes or FIFO generates an interrupt. The Arm must read the IFLAG Registers to determine which MB or FIFO caused the interrupt.
The other 5 interrupt sources (Bus Off, Error, Tx Warning, Rx Warning and Wake Up generate interrupts like the MB ones, and can be read from both the Error and Status Register 1 and 2. The Bus Off, Error, Tx Warning and Rx Warning interrupt mask bits are located in the Control 1 Register and the Wake-Up interrupt mask bit is located in the MCR.

44.8 Initialization/Application Information

This section provide instructions for initializing the FLEXCAN module.

44.8.1 FLEXCAN Initialization Sequence

The FLEXCAN module may be reset in two ways:

- SOC level hard reset which resets all memory mapped registers asynchronously
- SOFT_RST bit in MCR, which resets some of the memory mapped registers synchronously

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. The SOFT_RST bit remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset can not be applied while clocks are shut down in any of the low power modes. The low power mode should be exited and the clocks resumed before applying soft reset.

After the module is enabled (MDIS bit negated), FLEXCAN automatically goes to Freeze Mode. In Freeze Mode, FLEXCAN is un-synchronized to the CAN bus, the HALT and FRZ bits in MCR Register are set, the internal state machines are disabled and the FRZ_ACK and NOT_RDY bits in the MCR Register are set. The FLEXCAN_TX pin is in recessive state and FLEXCAN does not initiate any transmission or reception of CAN frames. Note that the Message Buffers and the Rx Individual Mask Registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FLEXCAN is put into Freeze Mode. The following is a generic initialization sequence applicable to the FLEXCAN module:

- Initialize the Module Configuration Register
  - Enable the individual filtering per MB and reception queue features by setting the IRMQ bit
  - Enable the warning interrupts by setting the WRN_EN bit
• If required, disable frame self reception by setting the SRX_DIS bit
• Enable the FIFO by setting the RFEN bit
• Enable the abort mechanism by setting the AEN bit
• Enable the local priority feature by setting the LPRIO_EN bit
• Initialize the Control Register
  • Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, RJW
  • Determine the bit rate by programming the PRESDIV field
  • Determine the internal arbitration mode (LBUF bit)
• Initialize the Message Buffers
  • The Control and Status word of all Message Buffers must be initialized
  • If FIFO was enabled, the 8-entry ID table must be initialized
  • Other entries in each Message Buffer should be initialized as required
• Initialize the Rx Individual Mask Registers
• Set required interrupt mask bits in the IMASK Registers (for all MB interrupts), in
  CTRL Register (for Bus Off and Error interrupts) and in MCR Register for Wake-Up
  interrupt
• Negate the HALT bit in MCR

Starting with the last event, FLEXCAN attempts to synchronize to the CAN bus.

### 44.9 FLEXCAN Memory Map/Register Definition

The complete memory map for a FLEXCAN module with 64 MBs capability is shown in
the following table. Each individual register is identified by its complete name and the
corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U).
Most of the registers can be configured to have either Supervisor or Unrestricted access
by programming the SUPV bit in the MCR Register. The MCR register allows only
Supervisor access regardless the SUPV bit state.

The FLEXCAN module stores CAN messages for transmission and reception using a
Mailboxes and Rx FIFO structure.

### 44.9.1 Module Configuration Register (FLEXCANx_MCR)

This register defines global system configurations, such as the module operation mode (e.g., low power) and maximum message buffer configuration.

Address: Base address + 0h offset

![Module Configuration Register Diagram]
### FLEXCANx_MCR field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31 MDIS</td>
<td>This bit controls whether FLEXCAN is enabled or not. When disabled, FLEXCAN shuts down the clocks to the CAN Protocol Interface and Message Buffer Management sub-modules. This is the only bit in MCR not affected by soft reset. See Module Disable Mode for more information.</td>
</tr>
<tr>
<td>1</td>
<td>Disable the FLEXCAN module</td>
</tr>
<tr>
<td>0</td>
<td>Enable the FLEXCAN module</td>
</tr>
<tr>
<td>30 FRZ</td>
<td>The FRZ bit specifies the FLEXCAN behavior when the HALT bit in the MCR Register is set or when Debug Mode is requested at Arm level. When FRZ is asserted, FLEXCAN is enabled to enter Freeze Mode. Negation of this bit field causes FLEXCAN to exit from Freeze Mode.</td>
</tr>
<tr>
<td>1</td>
<td>Enabled to enter Freeze Mode</td>
</tr>
<tr>
<td>0</td>
<td>Not enabled to enter Freeze Mode</td>
</tr>
<tr>
<td>29 RFEN</td>
<td>This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID Filter Table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 44-19 (see Arbitration and Matching Timing). This bit can only be written in Freeze mode as it is blocked by hardware in other modes.</td>

### FLEXCANx_MCR field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 27 NOT_RDY | This read-only bit indicates that FLEXCAN is either in Disable Mode, Stop Mode or Freeze Mode. It is negated once FLEXCAN has exited these modes.  
1. FLEXCAN module is either in Disable Mode, Stop Mode or Freeze Mode  
0. FLEXCAN module is either in Normal Mode, Listen-Only Mode or Loop-Back Mode |
| 26 WAK_MSK | This bit enables the Wake Up Interrupt generation.  
1. Wake Up Interrupt is enabled  
0. Wake Up Interrupt is disabled |
| 25 SOFT_RST | When this bit is asserted, FlexCAN resets its internal state machines and some of the memory mapped registers. The following registers are reset: MCR (except the MDIS bit), TIMER, ECR, ESR1, ESR2, IMASK1, IMASK2, IFLAG1, IFLAG2 and CRCR. Configuration registers that control the interface to the CAN bus are not affected by soft reset. The following registers are unaffected:  
CTRL1, CTRL2, RXIMR0_RXIMR63, RXGMASK, RX14MASK, RX15MASK, RXFIMGASK, RXFIR and all Message Buffers  
The SOFT_RST bit can be asserted directly by the Arm when it writes to the MCR Register. It may take some time to fully propagate its effect. The SOFT_RST bit remains asserted while reset is pending, and is automatically negated when reset completes. Therefore, software can poll this bit to know when the soft reset has completed.  
Soft reset cannot be applied while clocks are shut down in any of the low power modes. The module should be first removed from low power mode, and then soft reset can be applied.  
1. Reset the registers  
0. No reset request |
| 24 FRZ_ACK | This read-only bit indicates that FLEXCAN is in Freeze Mode and its prescaler is stopped. The Freeze Mode request cannot be granted until current transmission or reception processes have finished. Therefore the software can poll the FRZ_ACK bit to know when FLEXCAN has actually entered Freeze Mode. If Freeze Mode request is negated, then this bit is negated once the FLEXCAN prescaler is running again. If Freeze Mode is requested while FLEXCAN is in any of the low power modes, then the FRZ_ACK bit will only be set when the low power mode is exited. See Freeze Mode for more information  
1. FLEXCAN in Freeze Mode, prescaler stopped  
0. FLEXCAN not in Freeze Mode, prescaler running |
| 23 SUPV | This bit configures some of the FLEXCAN registers to be either in Supervisor or User Mode. Reset value of this bit is ‘1’, so the affected registers start with Supervisor access allowance only. This bit can only be written in Freeze mode as it is blocked by hardware in other modes.  
1. FlexCAN is in Supervisor Mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location  
0. FlexCAN is in User Mode. Affected registers allow both Supervisor and Unrestricted accesses |
| 22 SLF_WAK | This bit enables the Self Wake Up feature when FLEXCAN is in Stop Mode. If this bit had been asserted by the time FLEXCAN entered Stop Mode, then FLEXCAN will look for a recessive to dominant transition on the bus during these modes. If a transition from recessive to dominant is detected during Stop Mode, then FLEXCAN generates, if enabled to do so, a Wake Up interrupt to the Arm so that it can resume the clocks globally and FlexCAN can request to resume the clocks. This bit can not be written while the module is in Stop Mode.  
1. FLEXCAN Self Wake Up feature is enabled  
0. FLEXCAN Self Wake Up feature is disabled |
| 21 WRN_EN | When asserted, this bit enables the generation of the TWRN_INT and RWRN_INT flags in the Error and Status Register. If WRN_EN is negated, the TWRN_INT and RWRN_INT flags will always be zero,

</tr>
</tbody>
</table>

1. One time quantum is equal to the Sclock period.

### 44.9.3 Free Running Timer Register (FLEXCANx_TIMER)

This register represents a 16-bit free running counter that can be read and written by the Arm. The timer starts from $0000$ after Reset, counts linearly to $FFFF$, and wraps around.
The timer is clocked by the FLEXCAN bit-clock (which defines the baud rate on the CAN bus). During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. During Freeze Mode, disable, and stop mode, the timer is not incremented.

The timer value is captured at the beginning of the identifier field of any frame on the CAN bus. This captured value is written into the Time Stamp entry in a message buffer after a successful reception or transmission of a message.

If bit CTRL1[TSYN] is asserted the Timer is reset whenever a message is received in the first available Mailbox, according to CTRL2[RFFN] setting.

Arm can write to this register anytime. However, if the write occurs at the same time that the Timer is being reset by a reception in the first Mailbox, then the write value is discarded.

Reading this register affects the Mailbox Unlocking procedure. For additional details, refer to Message Buffer Lock Mechanism.

## 44.9.7 Error Counter Register (FLEXCANx_ECR)

This register has 2 8-bit fields reflecting the value of two FLEXCAN error counters: Transmit Error Counter (Tx_Err_Counter field) and Receive Error Counter (Rx_Err_Counter field). The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FLEXCAN module. Both counters are read only except in Freeze Mode, where they can be written by the Arm.
FLEXCAN responds to any bus state as described in the protocol, e.g. transmit 'Error Active' or 'Error Passive' flag, delay its transmission start time ('Error Passive') and avoid any influence on the bus when in 'Bus Off' state. The following are the basic rules for FLEXCAN bus state transitions.

- If the value of Tx_Err.Counter or Rx_Err.Counter increases to be greater than or equal to 128, the FLT_CONF field in the Error and Status Register is updated to reflect 'Error Passive' state.
- If the FLEXCAN state is 'Error Passive', and either Tx_Err.Counter or Rx_Err.Counter decrements to a value less than or equal to 127 while the other already satisfies this condition, the FLT_CONF field in the Error and Status Register is updated to reflect 'Error Active' state.
- If the value of Tx_Err.Counter increases to be greater than 255, the FLT_CONF field in the Error and Status Register is updated to reflect 'Bus Off' state, and an interrupt may be issued. The value of Tx_Err.Counter is then reset to zero.
- If FLEXCAN is in 'Bus Off' state, then Tx_Err.Counter is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, Tx_Err.Counter is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around while incrementing the Tx_Err.Counter. When Tx_Err.Counter reaches the value of 128, the FLT_CONF field in the Error and Status Register is updated to be 'Error Active' and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the Tx_Err.Counter value.
- If during system start-up, only one node is operating, then its Tx_Err.Counter increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACK_ERR bit in the Error and Status Register). After the transition to 'Error Passive' state, the Tx_Err.Counter does not increment anymore by acknowledge errors. Therefore the device never goes to the 'Bus Off' state.
- If the Rx_Err.Counter increases to a value greater than 127, it is not incremented further, even if more errors are detected while being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to resume to 'Error Active' state.

#### 44.9.8 Error and Status 1 Register (FLEXCANx_ESR1)

This register reflects various error conditions, some general status of the device and it is the source of four interrupts to the Arm.

The Arm read action clears bits 15-10, therefore the reported *error conditions* (bits 15-10) are those that occurred since the last time the Arm read this register. Bits 9-3 are status bits.

Some bits in this register are read-only and some are not.

### 44.9.9 Interrupt Masks 2 Register (FLEXCANx_IMASK2)

This register allows any number of a range of 32 Message Buffer Interrupts to be enabled or disabled. It contains one interrupt mask bit per buffer, enabling the Arm to determine which buffer generates an interrupt after a successful transmission or reception (i.e. when the corresponding IFLAG2 bit is set).

44.9.11 Interrupt Flags 2 Register (FLEXCANx_IFLAG2)

This register defines the flags for 32 Message Buffer interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing it to '1'. Writing '0' has no effect. Before updating MCR[MAXMB] field, Arm must treat the IFLAG2 bits which MB value is greater than the MCR[MAXMB] to be updated, otherwise they will keep set and be inconsistent with the amount of MBs available.

</tbody>
</table>

44.9.12 Interrupt Flags 1 Register (FLEXCANx_IFLAG1)

This register defines the flags for 32 Message Buffer interrupts and FIFO interrupts. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The Interrupt flag must be cleared by writing it to '1'. Writing '0' has no effect.

When the RFEN bit in the MCR is set (Rx FIFO enabled), the function of the 8 least significant interrupt flags (BUF7I - BUF0I) is changed to support the FIFO operation. BUF7I, BUF6I and BUF5I indicate operating conditions of the FIFO, while BUF4I to BUF0I are not used. Before enabling the RFEN, Arm must service the IFLAGS asserted in the Rx FIFO region (see Rx FIFO). Otherwise, these IFLAGS will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When the RFEN is negated, the FIFO flags must be cleared. The same care must be taken when a
RFFN value is selected extending Rx FIFO filters beyond MB7 (see Control 2 Register (FLEXCAN_CTRL2)). For example, when RFFN is 0x8, the MB0-23 range is occupied by Rx FIFO filters and related IFLAGS must be cleared.

Before updating MCR[MAXMB] field, Arm must service the IFLAG1 which MB value is greater than the MCR[MAXMB] to be updated, otherwise they will keep set and be inconsistent with the amount of MBs available.

**FLEXCANx_IFLAG1 field descriptions**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 31–8 BUF31I_BUF8I | Each bit flags the respective FLEXCAN Message Buffer (MB8 to MB31) interrupt.  
1 The corresponding MB has successfully completed transmission or reception  
0 No such occurrence |
| 7 BUF7I      | If the Rx FIFO is not enabled, this bit flags the interrupt for MB7.  
If the MCR[RFEN] bit is asserted, this flag indicates that a message was lost because Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox.  
This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by Arm writes.  
1 MB7 completed transmission/reception or FIFO overflow  
0 No such occurrence |
| 6 BUF6I      | If the Rx FIFO is not enabled, this bit flags the interrupt for MB6.  
If the MCR[RFEN] bit is asserted, this flag indicates when the number of unread messages within the Rx FIFO is increased to 5 from 4 due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared while the number of unread messages is greater than 4 it will not assert again until the number of unread messages within the Rx FIFO is decreased to equal or less than 4.  
This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by Arm writes.  
1 MB6 completed transmission/reception or FIFO almost full  
0 No such occurrence |
| 5 BUF5I      | If the Rx FIFO is not enabled, this bit flags the interrupt for MB5. If the Rx FIFO is enabled, this flag indicates that at least one frame is available to be read from the Rx FIFO.  
This flag is cleared by the FlexCAN whenever the bit MCR[RFEN] is changed by Arm writes.  
1 MB5 completed transmission/reception or FIFO almost full  
0 No such occurrence |

</table>

1. The number of the last remaining available mailboxes is defined by the MCR[MAXMB] field.
2. If Rx Individual Mask Registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

Each group of eight filters occupies a memory space equivalent to two Message Buffers which means that the more filters are implemented the less Mailboxes will be available.
Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words which can be calculated as follows:

\[(\text{SETUP}_\text{MB} - 6) \times 4\]

where SETUP_MB is MAXMB.

The number of remaining Mailboxes available will be:

\[\text{SETUP}_\text{MB} - 8 - (\text{RFFN} \times 2)\]

If the Number of Rx FIFO Filters programmed through RFFN exceeds the SETUP_MB value, the exceeding ones will not be functional. Unshaded regions in Table 44-23 indicate the valid combinations of MAXMB, RFEN and RFFN, shaded regions are not functional.

### FLEXCANx_CTRL2 field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>27–24 RFFN</td>
<td>This 4-bit field defines the number of Rx FIFO filters according to Table 44-22. The maximum selectable number of filters is determined by the Arm. This field can only be written in Freeze mode as it is blocked by hardware in other modes. RFFN defines a number of Message Buffers occupied by Rx FIFO and ID Filter (see Table 44-22) that may not exceed the number of available Mailboxes present in module, defined by MCR[MAXMB]. Default RFFN value is 0x0, which leads to a total of 8 Rx FIFO filters, occupies the first 8 Message Buffers (MB 0-7) and makes available the next Message Buffers (MB 8-63) for Mailboxes. As a second example, when RFFN is set to 0xD, there will be 112 Rx FIFO filters, located in MB 0-33, and MB 34-63 are available for Mailboxes. Notice that, in this case, individual masks (RXIMR) will just cover Rx FIFO filters in 0-31 range, and filters 32-111 will use RXFGMASK. In case of reducing the number of last Message Buffers, MCR[MAXMB] (see Module Configuration Register (FLEXCAN_MCR)) can be adjusted by the application to minimum of 33, in order to give room to the Rx FIFO and its ID Filter Table defined by RFFN. On the contrary, if the application sets MCR[MAXMB] to 16, for instance, the maximum RFFN is limited to 0x4. RFFN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 44-19 (see Arbitration and Matching Timing).</td>
</tr>
<tr>
<td>23–19 TASD</td>
<td>This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field is useful to optimize the transmit performance based on factors such as: peripheral/serial clock ratio, CAN bit timing and number of MBs. The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and CAN baud rate and inversely proportional to the peripheral clock frequency. The optimal arbitration timing is that in which the last MB is scanned right before the first bit of the Intermission field of a CAN frame. Therefore, if there are few MBs and the system/serial clock ratio is high and the CAN baud rate is low then the arbitration can be delayed and vice-versa. If TASD is 0 then the arbitration start is not delayed, thus Arm has less time to configure a Tx MB for the next arbitration. In the other hand, if TASD is 24 then Arm can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not able to find winner MBs in time to compete with other nodes for the CAN bus. If the arbitration ends too much time before the first bit of Intermission field then there is a chance that Arm reconfigure some Tx MBs and the winner MB is not the best to be transmitted. The reset value is different on various platforms, according to their peripheral clock frequency, number of MBs and target CAN baud rate. The optimal configuration for TASD can be calculated as:</td>
</tr>
</tbody>
</table>

\[
TASD = 25 - \left\{ \frac{f_{\text{CANCLK}} \times [\text{MAXMB} + 3 - (\text{RFEN} \times 8) - (\text{RFEN} \times \text{RFFN} \times 2)] \times 2}{f_{\text{sys}} \times [1 + (\text{PSEG1} + 1) + (\text{PSEG2} + 1) + (\text{PROPSEG} + 1)] \times (\text{PRESDIV} + 1)} \right\}
\]

where:

- \(f_{\text{CANCLK}}\) is the Protocol Engine (PE) Clock in Hz; PE clock is derived from CAN_CLK_ROOT in CCM. See the Clock controller module.

## FLEXCANx_ESR2 Field Descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–23</td>
<td>This field is reserved. Reserved</td>
</tr>
<tr>
<td>22–16</td>
<td>LPTM</td>
</tr>
<tr>
<td></td>
<td>If ESR2[VPS] is asserted, his 7-bit field indicates the lowest number inactive Mailbox (refer to IMB bit description). If there is no inactive Mailbox then the Mailbox indicated depends on CTRL1[LBUF] bit value. If CTRL1[LBUF] bit is negated then the Mailbox indicated is the one which has the greatest arbitration value (see Highest Mailbox priority first). If CTRL1[LBUF] bit is asserted then the Mailbox indicated is the highest number active Tx Mailbox. If a Tx Mailbox is being transmitted it is not considered in LPTM calculation. If ESR2[IMB] is not asserted and a frame is transmitted successfully, LPTM is updated with its Mailbox number.</td>
</tr>
<tr>
<td>15</td>
<td>This field is reserved. Reserved</td>
</tr>
<tr>
<td>14</td>
<td>VPS</td>
</tr>
<tr>
<td></td>
<td>This bit indicates whether IMB and LPTM contents are currently valid or not. VPS is asserted upon every complete Tx arbitration process unless the Arm writes to Control and Status word of a Mailbox that has already been scanned (i.e. it is behind Tx Arbitration Pointer) during the Tx arbitration process. If there is no inactive Mailbox and only one Tx Mailbox which is being transmitted then VPS is not asserted. VPS is negated upon the start of every Tx arbitration process or upon a write to Control and Status word of any Mailbox. ESR2[VPS] is not affected by any Arm write into Control Status (C/S) of a MB which is blocked by abort mechanism. When MCR[AEN] is asserted, the abort code write in C/S of a MB that is been transmitted (pending abort), or any write attempt into a Tx MB with IFLAG set is blocked.</td>

### 44.9.16 Rx FIFO Global Mask Register (FLEXCANx_RXFGMASK)

If Rx FIFO is enabled RXFGMASK is used to mask the Rx FIFO ID Filter Table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze Mode as it is blocked by hardware in other modes.

#### Table 44-24. Rx FIFO Global Mask usage

### 44.9.17 Rx FIFO Information Register (FLEXCANx_RXFIR)

Rx FIFO provides information on Rx FIFO.

This register is the port through which Arm accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO as well as its output is updated whenever the output of the Rx FIFO is updated with the next message. Refer to Rx FIFO to find instructions on reading this register.

(refer to Rx FIFO for details) If multiple filters match the incoming message ID then the first matching IDAF found (lowest number) by the matching process is indicated. This field is valid only while the IFLAG[BUF5I] is asserted.</td>
</tr>
</tbody>
</table>
44.9.18  Rx Individual Mask Registers (FLEXCANx_RXIMRn)

RXIMR are used as acceptance masks for ID filtering in Rx MBs and the Rx FIFO. If the Rx FIFO is not enabled, one mask register is provided for each available Mailbox, providing ID masking capability on a per Mailbox basis.

When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), up to 32 Rx Individual Mask Registers can apply to the Rx FIFO ID Filter Table elements on a one-to-one correspondence depending on CTRL2[RFFN] setting. Refer to Control 2 Register (FLEXCAN_CTRL2) for details.

RXIMR can only be written by the Arm while the module is in Freeze Mode, otherwise they are blocked by hardware.

The Individual Rx Mask Registers are not affected by reset and must be explicitly initialized prior to any reception.

45.2 Introduction
The FlexCAN module is a communication controller implementing the CAN protocol according to the ISO 11898-1 standard and CAN 2.0 B protocol specifications. A general block diagram is shown in Figure 45-1, which describes the main subblocks implemented in the FlexCAN module, including:

- One associated memory for storing message buffers
- Receive Global Mask registers
- Receive Individual Mask registers
- Receive FIFO filters
- Receive FIFO ID filters

The functions of the submodules are described in subsequent sections.
NOTE

Rx FIFO cannot be used in FD mode.

![FlexCAN block diagram](image)

**Figure 45-1. FlexCAN block diagram**

### 45.2.1 Overview

The CAN protocol was primarily designed to be used as a vehicle serial data bus, meeting the specific requirements of this field:

- Real-time processing
- Reliable operation in the EMI environment of a vehicle
- Cost-effectiveness
- Required bandwidth

The FlexCAN module is a full implementation of the CAN protocol specification, the CAN with Flexible Data rate (CAN FD) protocol, and the CAN 2.0 version B protocol, which supports both standard and extended message frames and long payloads up to 64 bytes, transferred at faster rates (up to 8 Mb/s). The message buffers are stored in an embedded RAM dedicated to the FlexCAN module. See the chip-specific FlexCAN information for the actual number of message buffers configured in the chip.

The Protocol Engine (PE) submodule manages the serial communication on the CAN bus:

- Requesting RAM access for receiving and transmitting message frames
- Validating received messages
• Performing error handling
• Detecting CAN FD messages

The Controller Host Interface (CHI) submodule manages message buffer selection for reception and transmission, taking care of arbitration and ID matching algorithms for both CAN FD and non-CAN FD message formats.

The Bus Interface Unit (BIU) submodule controls access to and from the internal interface bus, in order to establish connection to the CPU and to other blocks. Clocks, address and data buses, interrupt outputs, DMA and test signals are accessed through the BIU.

### 45.2.2 FlexCAN module features

The FlexCAN module includes these distinctive features:

- Full implementation of the CAN with Flexible Data Rate (CAN FD) protocol specification and CAN protocol specification, Version 2.0 B
  - Standard data frames
  - Extended data frames
  - Zero to sixty four bytes data length
  - Programmable bit rate (see the chip-specific FlexCAN information for the specific maximum rate configuration)
  - Content-related addressing
- Compliant with the ISO 11898-1 standard
- Flexible mailboxes configurable to store 0 to 8, 16, 32, or 64 bytes data length
- Each mailbox configurable as receive or transmit, all supporting standard and extended messages
- Individual Rx Mask registers per mailbox
- Full-featured Rx FIFO with storage capacity for up to six frames and automatic internal pointer handling with DMA support
- Transmission abort capability
- Flexible message buffers (MBs), totaling 64 message buffers of 8 bytes data length each, configurable as Rx or Tx
- Programmable clock source to the CAN Protocol Interface, either peripheral clock or oscillator clock
- RAM not used by reception or transmission structures can be used as general purpose RAM space
- Listen-Only mode capability
- Programmable Loop-Back mode supporting self-test operation
• Programmable transmission priority scheme: lowest ID, lowest buffer number, or highest priority
• Time stamp based on 16-bit free running timer, with an optional external time tick
• Global network time, synchronized by a specific message
• Maskable interrupts
• Independence from the transmission medium (an external transceiver is assumed)
• Short latency time due to an arbitration scheme for high-priority messages
• Low power modes, with programmable wakeup on bus activity
• Transceiver delay compensation feature when transmitting CAN FD messages at faster data rates
• Remote request frames may be managed automatically or by software
• CAN bit time settings and configuration bits can only be written in Freeze mode
• Tx mailbox status (Lowest priority buffer or empty buffer)
• Identifier Acceptance Filter Hit Indicator (IDHIT) register for received frames
• SYNCH bit available in Error in Status 1 register to indicate that the module is synchronous with CAN bus
• CRC status for transmitted message
• Rx FIFO Global Mask register
• Selectable priority between mailboxes and Rx FIFO during matching process
• Powerful Rx FIFO ID filtering, capable of matching incoming IDs against either 128 extended, 256 standard, or 512 partial (8 bit) IDs, with up to 32 individual masking capability
• 100% backward compatibility with previous FlexCAN version

45.2.3 Modes of operation

The FlexCAN module has these functional modes:

• Normal mode (User or Supervisor):

  In Normal mode, the module operates receiving and/or transmitting message frames, errors are managed normally, and all CAN Protocol functions are enabled. User and Supervisor modes differ in the access to some restricted control registers.

• Freeze mode:

  Freeze mode is enabled when MCR[FRZ] is asserted. If enabled, Freeze mode is entered when MCR[HALT] is set or when Debug mode is requested at chip level and MCR[FRZ_ACK ] is asserted by the FlexCAN. In this mode, no transmission or reception of frames is done and synchronicity to the CAN bus is lost. See Freeze mode for more information.

• Loop-Back mode:
The module enters this mode when CTRL1[LPB] is asserted. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is internally fed back to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic '1'). FlexCAN behaves as it normally does when transmitting and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field to ensure proper reception of its own message. Both transmit and receive interrupts are generated.

- **Listen-Only mode:**

  The module enters this mode when CTRL1[LOM] is asserted. In this mode, transmission is disabled, all error counters are frozen, and the module operates in a CAN Error Passive mode. Only messages acknowledged by another CAN station will be received. If FlexCAN detects a message that has not been acknowledged, it will flag a BIT0 error (without changing the REC), as if it was trying to acknowledge the message.

- **CAN FD Active mode:**

  In this mode, FlexCAN is capable of transmitting and receiving all messages formatted according to the CAN FD Protocol and CAN 2.0 Protocol 2.0 in an interleaved fashion. The CPU can set the FlexCAN into CAN FD Active mode by configuring MCR[FDEN] in Freeze mode.

  It is important to know which features are available in CAN FD active mode. This table lists the differences between FD and classical modes.

<table>
<thead>
<tr>
<th>Feature</th>
<th>CAN classical</th>
<th>CAN FD</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rx FIFO DMA</td>
<td>Yes</td>
<td>No</td>
</tr>
<tr>
<td>Rx FIFO</td>
<td>Yes</td>
<td>No</td>
</tr>
</tbody>
</table>

  For low-power operation, the FlexCAN module has:

  - **Module Disable mode:**

    This low-power mode is entered when MCR[MDIS] is asserted by the CPU and MCR[LPM_ACK] is asserted by FlexCAN. When disabled, the module issues a request to disable the clocks to the CAN Protocol Engine and Controller Host Interface submodules. Exit from this mode is done by negating MCR[MDIS]. See Module Disable mode for more information.
• Doze mode:

This low power mode is entered when MCR[DOZE] is asserted and Doze mode is requested at chip level, and MCR[LPM_ACK] is asserted by FlexCAN. When in Doze mode, the module issues a request to disable the clocks to the CAN Protocol Engine and the CAN Controller-Host Interface submodules. Exit from this mode happens when MCR[DOZE] is negated, when the chip is removed from Doze mode, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See Doze mode for more information.

• Stop mode:

This low power mode is entered when Stop mode is requested at chip level and MCR[LPM_ACK] is asserted by the FlexCAN. When in Stop Mode, the module puts itself in an inactive state and then informs the CPU that the clocks can be shut down globally. Exit from this mode happens when the Stop mode request is removed, or when activity is detected on the CAN bus and the Self Wake Up mechanism is enabled. See Stop mode for more information.

### 45.3 FlexCAN signal descriptions

The FlexCAN module has two I/O signals connected to the external chip pins. These signals are summarized in the following table and described in more detail in the next subsections.

<table>
<thead>
<tr>
<th>Signal</th>
<th>Description</th>
<th>I/O</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAN Rx</td>
<td>CAN receive pin</td>
<td>Input</td>
</tr>
<tr>
<td>CAN Tx</td>
<td>CAN transmit pin</td>
<td>Output</td>
</tr>
</tbody>
</table>

### 45.3.1 CAN Rx

This pin is the receive pin from the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.
45.3.2 CAN Tx

This pin is the transmit pin to the CAN bus transceiver. Dominant state is represented by logic level 0. Recessive state is represented by logic level 1.

45.4 Functional description

The FlexCAN module is a CAN protocol engine with a very flexible mailbox system for transmitting and receiving CAN frames. The mailbox system is composed of a set of message buffers (MB) that store configuration and control data, time stamp, message ID, and data (see Message buffer structure). The memory corresponding to the first 38 MBs can be configured to support a FIFO reception scheme with a powerful ID filtering mechanism, capable of checking incoming frames against a table of IDs (up to 128 extended IDs or 256 standard IDs or 512 8-bit ID slices), with individual mask register for up to 32 ID filter table elements.

For Classical CAN frames, simultaneous reception through FIFO and mailbox is supported. For CAN FD frames, reception is supported through mailboxes only. For mailbox reception, a matching algorithm makes it possible to store received frames only into MBs that have the same ID programmed in the ID field. A masking scheme makes it possible to match the ID programmed on the MB with a range of IDs on received CAN frames. For transmission, an arbitration algorithm decides the prioritization of MBs to be transmitted based on the message ID (optionally augmented by 3 local priority bits) or the MB ordering.

Before proceeding with the functional description, an important concept must be explained. A message buffer is said to be active at a given time if it can participate in both the matching and arbitration processes. An Rx MB with a 0b0000 code is inactive (see Table 45-24). Similarly, a Tx MB with a 0b1000 or 0b1001 code is also inactive (see Table 45-25).

The FlexCAN module is also able to receive and transmit messages in CAN FD format. The message buffers are sized to adequately store the quantity of data bytes selected by the FDCTRL[MBDSRn] fields. The quantity of FD MBs available for a given quantity of data bytes is described in the FDCTRL register. See also FlexCAN memory partition for CAN FD.

45.4.1 Transmit process

To transmit a CAN frame, the CPU must prepare a message buffer for transmission by executing the following procedure:
1. Check whether the respective interrupt bit is set and clear it.
2. If the MB is active (transmission pending), write the ABORT code (0b1001) to the CODE field of the Control and Status word to request an abort of the transmission.
3. Wait for the corresponding IFLAG bit to be asserted by polling the IFLAG register, or by the interrupt request if enabled by the respective IMASK bit.
4. Read back the CODE field to check if the transmission was aborted or transmitted (see Transmission abort mechanism).
5. Clear the corresponding interrupt flag.
6. Write the ID register (containing the local priority if enabled via MCR[LPRIO_EN]).
7. Write payload data bytes.
8. Configure the Control and Status word with the desired configuration.
   a. Set ID type via MB_CS[IDE].
   b. Set Remote Transmission Request (if needed) via MB_CS[RTR].
   c. If MCR[FDEN] is enabled, also configure the MB_CS[EDL] and MB_CS[BRS] fields. For details about the relationship between the written value and transmitted value of the MB_CS[ESI] field, see Table 45-8.\(^1\)
   d. Set Data Length Code in bytes via MB_CS[DLC]. See Table 45-26 for detailed information.
   e. Activate the message buffer to transmit the CAN frame by setting MB_CS[CODE] to 0xC.

**NOTE**

It is strongly recommended that all the fields in MB_CS word be configured in only one 32-bit write operation to maximize software performance. If the fields are configured in separate writes, the MB_CS[CODE] must be the last write in the C/S word.

When the MB is activated, it participates in the arbitration process and is eventually transmitted according to its priority. When the DLC value stored in the MB selected for transmission is larger than the respective MB payload size, FlexCAN adds the necessary number of bytes with constant 0xCC pattern to complete the expected DLC.

At the end of the successful transmission:
- The value of the free running timer is written into the Time Stamp field.
- The CODE field in the Control and Status word is updated.
- Both CRC and FDCRC registers are updated.

---

\(^1\) The ESI field does not need to be written, and will automatically be transmitted dominant by error active nodes and recessive by error passive nodes. Note that there is an exception if the FlexCAN is operating as a network gateway: In that case, the CPU writes the MB_CS[ESI] bit according to the error status of the node which sent the message.
A status flag is set in the Interrupt Flag register.
An interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The new CODE field after transmission depends on the code that was used to activate the MB (see Table 45-24 and Table 45-25 in Message buffer structure).

When the Abort feature is enabled (MCR[AEN] is asserted), after the Interrupt flag is asserted for a mailbox configured as transmit buffer, the mailbox is blocked. Therefore the CPU is not able to update it until the Interrupt Flag is negated by the CPU. This means that the CPU must clear the corresponding IFLAG bit before starting to prepare this MB for a new transmission or reception.

**NOTE**

If backwards compatibility is desired (MCR[AEN] is negated), write the INACTIVE code (0b1000) to the CODE field to inactivate the MB. However, in this case the pending frame may be transmitted without notification (see Mailbox inactivation).

45.4.2 Arbitration process

The arbitration process scans the mailboxes, searching for the Tx mailbox that holds the message to be sent in the next opportunity. This mailbox is called the arbitration winner.

The scan starts from the lowest number mailbox and runs toward the higher ones.

The arbitration process is triggered in the following events:

- From the CRC field of the CAN frame. The start point depends on the value of CTRL2[TASD].
- During the Error Delimiter field of a CAN frame.
- During the Overload Delimiter field of a CAN frame.
- When the winner is inactivated and the CAN bus has still not reached the first bit of the Intermission field.
- When there is a CPU write to the C/S word of a winner MB and the CAN bus has still not reached the first bit of the Intermission field.
- When CHI is in Idle state and the CPU writes to the C/S word of any MB.
- When FlexCAN exits Bus Off state.
- Upon leaving Freeze mode or Low Power mode.

If the arbitration process does not manage to evaluate all mailboxes before the CAN bus has reached the first bit of the Intermission field, the temporary arbitration winner is invalidated and the FlexCAN will not compete for the CAN bus in the next opportunity.
The arbitration process selects the winner among the active Tx mailboxes at the end of the scan according to the settings of both CTRL1[LBUF] and MCR[LPRIOEN].

### 45.4.2.1 Lowest-number mailbox first

If CTRL1[LBUF] is asserted, the first (lowest number) active Tx mailbox found is the arbitration winner. MCR[LPRIOEN] has no effect when CTRL1[LBUF] is asserted.

### 45.4.2.2 Highest-priority mailbox first

If CTRL1[LBUF] is negated, then the arbitration process searches the active Tx mailbox with the highest priority, which means that this mailbox’s frame would have a higher probability to win the arbitration on CAN bus when multiple external nodes compete for the bus at the same time.

The sequence of bits considered for this arbitration is called the *arbitration value* of the mailbox. The highest-priority Tx mailbox is the one that has the lowest arbitration value among all Tx mailboxes.

If two or more mailboxes have equivalent arbitration values, the mailbox with the lowest number is the arbitration winner.

The composition of the arbitration value depends on the MCR[LPRIOEN] setting.

#### 45.4.2.2.1 Local priority disabled

If MCR[LPRIOEN] is negated the arbitration value is built in the exact sequence of bits as they would be transmitted in a CAN frame (see the following table) in such a way that the local priority is disabled.

<table>
<thead>
<tr>
<th>Format</th>
<th>Mailbox arbitration value (32 bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard (IDE = 0)</td>
<td>Standard ID (11 bits) RTR (1 bit) IDE (1 bit) - (18 bits) - (1 bit)</td>
</tr>
<tr>
<td>Extended (IDE = 1)</td>
<td>Extended ID[28:18] (11 bits) SRR (1 bit) IDE (1 bit) Extended ID[17:0] (18 bits) RTR (1 bit)</td>
</tr>
</tbody>
</table>

#### 45.4.2.2.2 Local priority enabled

To enable local priority, MCR[LPRIOEN] must be asserted. In this case the mailbox PRIO field is included at the very left of the arbitration value (see the following table).
Table 45-5. Composition of the arbitration value when local priority is enabled

<table>
<thead>
<tr>
<th>Format</th>
<th>Mailbox arbitration value (35 bits)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Standard (IDE = 0)</td>
<td>PRIO (3 bits) Standard ID (11 bits) RTR (1 bit) IDE (1 bit) - (18 bits) - (1 bit)</td>
</tr>
<tr>
<td>Extended (IDE = 1)</td>
<td>PRIO (3 bits) Extended ID[28:18] (11 bits) SRR (1 bit) IDE (1 bit) Extended ID[17:0] (18 bits) RTR (1 bit)</td>
</tr>
</tbody>
</table>

Because the PRIO field is the most significant part of the arbitration value, mailboxes with low PRIO values have higher priority than mailboxes with high PRIO values regardless of the rest of their arbitration values.

Note that the PRIO field is not part of the frame on the CAN bus. Its purpose is only to affect the internal arbitration process.

**45.4.2.3 Arbitration process (continued)**

After the arbitration winner is found, its content is copied to a hidden auxiliary MB called Tx Serial Message Buffer (Tx SMB), which has the same structure as a normal MB but is not user accessible. This operation is called move-out and after it is done, write access to the C/S word of the corresponding MB is blocked (if MCR[AEN] is asserted). Write access is restored in the following events:

- After the MB is transmitted and the corresponding IFLAG bit is cleared by the CPU.
- FlexCAN enters Freeze mode or Bus Off.
- FlexCAN loses the bus arbitration or there is an error during the transmission.

At the first opportunity window on the CAN bus, the message on the Tx SMB is transmitted according to the CAN protocol rules.

Arbitration process can be triggered in the following situations:

- During Rx and Tx frames from CAN CRC field to end of frame. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During CAN Bus Off state from TX_ERR_CNT=124 to 128. CTRL2[TASD] value may be changed to optimize the arbitration start point.
- During C/S write by CPU in Bus Idle. First C/S write starts arbitration process, and a second C/S write during this same arbitration restarts the process. If other C/S writes are performed, Tx arbitration process is pending. If there is no arbitration winner after the arbitration process has finished, then the TX arbitration machine begins a new arbitration process. If there is a pending arbitration and Bus Idle state starts, then an arbitration process is triggered. In this case the first and second C/S write in Bus Idle will not restart the arbitration process. It is possible that there is not enough time...
to finish arbitration in Wait For Bus Idle state and the next state is Idle. In this case
the scan is not interrupted, and it is completed during Bus Idle state. During this
arbitration C/S write does not cause arbitration restart.

- Arbitration winner deactivation during a valid arbitration window.
- Upon exiting Freeze mode (first bit of the Wait For Bus Idle state). If there is a re-
synchronization during Wait For Bus Idle, the arbitration process is restarted.

Arbitration process stops in the following situations:

- All mailboxes were scanned.
- A Tx active mailbox is found if lowest buffer feature is enabled.
- Arbitration winner inactivation or abort during any arbitration process.
- There was not enough time to finish Tx arbitration process (for instance, when a
deactivation was performed near the end of frame). In this case arbitration process is
pending.
- Error or overload flag in the bus.
- Low Power or Freeze mode request in Idle state.

Arbitration is considered pending as described below:

- It was not possible to finish arbitration process in time.
- C/S write during arbitration if write is performed in a MB whose number is lower
than the Tx arbitration pointer.
- Any C/S write if there is no Tx arbitration process in progress.
- Rx Match has just updated a Rx code to Tx code.
- Entering Bus Off state.

C/S write during arbitration has the following effect:

- If C/S write is performed in the arbitration winner, a new process is restarted
immediately.
- If C/S write is performed in a MB whose number is higher than the Tx arbitration
pointer, the ongoing arbitration process will scan this MB as normal.

45.4.3 Receive process

To be able to receive CAN frames into a mailbox, the CPU must prepare it for reception
by executing the following steps:

1. If the mailbox is active (either Tx or Rx) inactivate the mailbox (see Mailbox
   inactivation), preferably with a safe inactivation (see Transmission abort
   mechanism).
2. Write the ID word
3. Write the EMPTY code (0b0100) to the CODE field of the Control and Status word to activate the mailbox. No setup is required for EDL, BRS, and ESI bits—they are overwritten by the respective bit fields in the received message.

After the MB is activated, it will be able to receive frames that match the programmed filter. At the end of a successful reception, the mailbox is updated by the move-in process (see Move-in) as follows:

1. The received data field (8 bytes at most for Classical CAN message format and up to 64 bytes for CAN FD message format) is stored.
2. The received Identifier field is stored.
3. The value of the Free Running Timer at the time of the second bit of frame's Identifier field is written into the mailbox's Time Stamp field.
4. The received SRR, IDE, RTR, EDL, BRS, ESI, and DLC fields are stored.
5. The CODE field in the Control and Status word is updated (see Table 45-24 and Table 45-25 in Section Message buffer structure).
6. A status flag is set in the Interrupt Flag Register and an interrupt is generated if allowed by the corresponding Interrupt Mask Register bit.

The recommended way for the CPU to service (read) the frame received in a mailbox is by the following procedure:

1. Read the Control and Status word of that mailbox.
2. Check if the BUSY bit is deasserted, indicating that the mailbox is locked. Repeat step 1) while it is asserted. See Mailbox lock mechanism.
3. Read the contents of the mailbox. After the mailbox is locked, its contents won't be modified by FlexCAN move-in processes. See Move-in.
4. Acknowledge the proper flag at IFLAG registers.
5. Read the free running timer. It is optional but recommended to unlock the mailbox as soon as possible and make it available for reception.

The CPU should poll for frame reception by the status flag bit for the specific mailbox in one of the IFLAG registers and not by the CODE field of that mailbox. Polling the CODE field does not work because after a frame is received and the CPU services the mailbox (by reading the C/S word followed by unlocking the mailbox), the CODE field will not return to EMPTY. It will remain FULL, as explained in Table 45-24. If the CPU tries to work around this behavior by writing to the C/S word to force an EMPTY code after reading the mailbox without a prior safe inactivation, a newly received frame matching the filter of that mailbox may be lost.

**CAUTION**

In summary: never do polling by reading directly the C/S word of the mailboxes. Instead, read the IFLAG registers.
Note that the received frame's Identifier field is always stored in the matching mailbox, thus the contents of the ID field in a mailbox may change if the match was due to masking. When MCR[SRXDIS] is asserted, FlexCAN will not store frames transmitted by itself in any MB, even if it contains a matching Rx mailbox, and no interrupt flag or interrupt signal will be generated. Otherwise, when MCR[SRXDIS] is deasserted, FlexCAN can receive frames transmitted by itself if a matching Rx mailbox exists.

To be able to receive CAN frames through the Rx FIFO, the CPU must enable and configure the Rx FIFO during Freeze mode (see Rx FIFO). Upon receiving the Frames Available in Rx FIFO interrupt (see the description of IFLAG1[BUF5I] "Frames available in Rx FIFO"), the CPU should service the received frame using the following procedure:

1. Read the Control and Status word (optional: needed only if a mask was used for IDE and RTR bits).
2. Read the ID field (optional: needed only if a mask was used).
3. Read the data field.
4. Read the RXFIR register (optional).
5. Clear the Frames Available in Rx FIFO interrupt by writing one to IFLAG1[BUF5I] (mandatory: releases the MB and allows the CPU to read the next Rx FIFO entry).

When MCR[DMA] is asserted, upon receiving a frame in FIFO, IFLAG1[BUF5I] generates a DMA request and does not generate a CPU interrupt (see Rx FIFO under DMA operation). The IMASK1 bits in Rx FIFO region are not used.

The DMA controller must service the received frame using the following procedure:

1. Read the Control and Status word (read 0x80 address, optional).
2. Read the ID field (read 0x84 address, optional).
3. Read all data bytes (start read at 0x88 address, optional).
4. Read the last data bytes (read 0x8C address is mandatory).

### 45.4.4 Matching process

The matching process scans the MB memory looking for Rx MBs programmed with the same ID as the one received from the CAN bus. If the FIFO is enabled, the priority of scanning can be selected between mailboxes and FIFO filters. The matching starts from the lowest number message buffer toward the higher ones. If no match is found within the first structure then the other is scanned subsequently. In the event that the FIFO is full, the matching algorithm always looks for a matching MB outside the FIFO region.

For Rx FIFO see Rx FIFO.
As the frame is being received, it is stored in a hidden auxiliary MB called Rx Serial Message Buffer (Rx SMB).

The matching process start point depends on the following conditions:

- If the received frame is a remote frame, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field equal to zero, the start point is the CRC field of the frame.
- If the received frame is a data frame with DLC field different than zero, the start point is the DATA field of the frame.

If a matching ID is found in the FIFO table or in one of the mailboxes, the contents of the Rx SMB are transferred to the FIFO or to the matched mailbox by the move-in process. If any CAN protocol error is detected then no match results are transferred to the FIFO or to the matched mailbox at the end of reception.

The matching process scans all matching elements of both Rx FIFO (if enabled) and the active Rx mailboxes (CODE is EMPTY, FULL, OVERRUN, or RANSWER) in search of a successful comparison with the matching elements of the Rx SMB that is receiving the frame on the CAN bus. The Rx SMB has the same structure as a mailbox. The reception structures (Rx FIFO or mailboxes) associated with the matching elements that had a successful comparison are the matched structures. The matching winner is selected at the end of the scan among those matched structures and depends on conditions described ahead. See the following table.

<table>

<td>cmp_msk</td>
<td>cmp_msk</td>
<td>cmp_msk</td>
<td>—</td>
</tr>
</tbody>
</table>

1. For mailbox structure, If SMB[IDE] is asserted, the ID is 29 bits (ID Standard + ID Extended). If SMB[IDE] is negated, the ID is only 11 bits (ID Standard). For FIFO structure, the ID depends on IDAM.
2. cmp: Compares the Rx SMB contents with the MB contents regardless the masks.
3. no_cmp: The Rx SMB contents are not compared with the MB contents.
4. cmp_msk: Compares the Rx SMB contents with MB contents taking into account the masks.
5. SMB[IDE] and SMB[RTR] are not taken into account when IDAM is type C.

A reception structure is free-to-receive when any of the following conditions is satisfied:

- The CODE field of the mailbox is EMPTY.
- The CODE field of the mailbox is either FULL or OVERRUN and it has already been serviced (the C/S word was read by the CPU and unlocked as described in Mailbox lock mechanism).
- The CODE field of the mailbox is either FULL or OVERRUN and an inactivation (see Mailbox inactivation) is performed.
- The Rx FIFO is not full.

The scan order for mailboxes and Rx FIFO is from the matching element with lowest number to the higher ones.

The matching winner search for mailboxes is affected by MCR[IRMQ]. If it is negated, the matching winner is the first matched mailbox regardless if it is free-to-receive or not. If it is asserted, the matching winner is selected according to the priority below:

1. the first free-to-receive matched mailbox;
2. the last non free-to-receive matched mailbox.

It is possible to select the priority of scan between mailboxes and Rx FIFO with CTRL2[MRP].

If the selected priority is Rx FIFO first:

- If the Rx FIFO is a matched structure and is free-to-receive, then the Rx FIFO is the matching winner regardless of the scan for mailboxes.
- Otherwise (the Rx FIFO is not a matched structure or is not free-to-receive), then the matching winner is searched among mailboxes as described above.

If the selected priority is mailboxes first:

- If a free-to-receive matched mailbox is found, it is the matching winner regardless of the scan for Rx FIFO.
- If no matched mailbox is found, then the matching winner is searched in the scan for the Rx FIFO.
- If both conditions above are not satisfied and a non–free-to-receive matched mailbox is found, then the matching winner determination is conditioned by MCR[IRMQ]:
  - If MCR[IRMQ] is negated, the matching winner is the first matched mailbox.
  - If MCR[IRMQ] is asserted, the matching winner is the Rx FIFO if it is a free-to-receive matched structure; otherwise, the matching winner is the last non–free-to-receive matched mailbox.
See the following table for a summary of matching possibilities.

</table>
1. This is a don't care condition.
2. Matched in MB "None" means that the frame has not matched any MB (free-to-receive or non–free-to-receive).
3. This is a forbidden condition.
4. Matched in MB "Free" means that the frame matched at least one MB free-to-receive regardless of whether it has matched MBs non-free-to-receive.
5. Matched in FIFO "None" means that the frame has not matched any filter in FIFO. It is as if the FIFO didn't exist (CTRL2[RFEN]=0).
6. Matched in FIFO "Not full" means that the frame has matched a FIFO filter and has empty slots to receive it.
7. Matched in FIFO "Full" means that the frame has matched a FIFO filter but couldn't store it because it has no empty slots to receive it.

If a non-safe mailbox inactivation (see Mailbox inactivation) occurs during matching process and the mailbox inactivated is the temporary matching winner, then the temporary matching winner is invalidated. The matching elements scan is not stopped nor restarted—it continues normally. The consequence is that the current matching process works as if the matching elements compared before the inactivation did not exist, therefore a message may be lost.

Suppose, for example, that the FIFO is disabled, IRMQ is enabled, there are two MBs with the same ID, and FlexCAN starts receiving messages with that ID. Let us say that these MBs are the second and the fifth in the array. When the first message arrives, the matching algorithm finds the first match in MB number 2. The code of this MB is EMPTY, so the message is stored there. When the second message arrives, the matching algorithm finds MB number 2 again, but it is not "free-to-receive", so it keeps looking, finds MB number 5 and stores the message there. If yet another message with the same ID arrives, the matching algorithm finds out that there are no matching MBs that are "free-to-receive", so it decides to overwrite the last matched MB, which is number 5. In doing so, it sets the CODE field of the MB to indicate OVERRUN.

The ability to match the same ID in more than one MB can be exploited to implement a reception queue (in addition to the full featured FIFO) to allow more time for the CPU to service the MBs. By programming more than one MB with the same ID, received messages are queued into the MBs. The CPU can examine the Time Stamp field of the MBs to determine the order in which the messages arrived.

Matching to a range of IDs is possible by using ID acceptance masks. FlexCAN supports individual masking per MB (see the description of Rx Individual Mask registers (RXIMR0 - RXIMR63)). During the matching algorithm, if a mask bit is asserted, then the corresponding ID bit is compared. If the mask bit is negated, the corresponding ID bit is a "don't care". Note that the Individual Mask Registers are implemented in RAM, so they are not initialized out of reset. Also, they can only be programmed when the module is in Freeze mode; otherwise, they are blocked by hardware.

FlexCAN also supports an alternate masking scheme with only four mask registers (RXFGMASK, RXMGMASK, RX14MASK, and RX15MASK) for backwards compatibility with legacy applications. This alternate masking scheme is enabled when the IRMQ bit in the MCR register is negated.
45.4.5 Move process

There are two types of move process: move-in and move-out.

45.4.5.1 Move-in

The move-in process is the copy of a message received by an Rx SMB to an Rx mailbox or FIFO that has matched it. If the move destination is the Rx FIFO, attributes of the message are also copied to the CAN_RXFIR FIFO. Each Rx SMB has its own move-in process, but only one is performed at a given time as described ahead. The move-in starts only when the message held by the Rx SMB has a corresponding matching winner (see Matching process) and all of the following conditions are true:

- The CAN bus has either reached or already gone past:
  - The second bit of Intermission field next to the frame that carried the message that is in the Rx SMB.
  - The first bit of an overload frame next to the frame that carried the message that is in the Rx SMB.
- There is no ongoing matching process.
- The destination mailbox is not locked by the CPU.
- There is no ongoing move-in process from another Rx SMB. If more than one move-in process is to be started at the same time, both are performed and the newest substitutes for the oldest.

The term pending move-in is used throughout the documentation and stands for a move-to-be that still does not satisfy all of the aforementioned conditions.

The move-in is cancelled and the Rx SMB is able to receive another message if any of the following conditions is satisfied:

- The destination mailbox is inactivated after the CAN bus has reached the first bit of Intermission field next to the frame that carried the message and its matching process has finished.
- There is a previous pending move-in to the same destination mailbox.
- The Rx SMB is receiving a frame transmitted by the FlexCAN itself and self-reception is disabled (MCR[SRXDIS] is asserted).
- Any CAN protocol error is detected.
Note that the pending move-in is not cancelled if the module enters Freeze or Low-Power mode. It stays on hold, only waiting for Freeze and Low-Power mode to be exited and the module to be unlocked. If an MB is unlocked during Freeze mode, the move-in happens immediately.

The move-in process is the execution by the FlexCAN of the following steps:

1. Push IDHIT into the RXFIR FIFO if the message is destined for the Rx FIFO.
2. Read all data words from the Rx SMB in accordance with the selected payload size for the Rx storage element.
3. Write all data words to the Rx mailbox in accordance with the selected payload size for the Rx storage element. If the data size of the storage element is smaller than the original payload size described in the message's DLC field, the payload is truncated and the high order bytes that do not fit the destination size are lost.
4. Read the Control/Status and ID words from the Rx SMB.
5. Write Control/Status and ID words to the Rx mailbox, and update the CODE field.

The move-in process is not atomic, in such a way that it is immediately cancelled by the inactivation of the destination mailbox (see Mailbox inactivation). In this case the mailbox may remain partially updated, thus incoherent. The exception is if the move-in destination is a Rx FIFO message buffer; then the process cannot be cancelled.

The BUSY Bit (least significant bit of the CODE field) of the destination message buffer is asserted while the move-in is being performed to alert the CPU that the message buffer content is temporarily incoherent.

### 45.4.5.2 Move-out

The move-out process is the copy of the content from a Tx Mailbox to the Tx SMB when a message for transmission is available (see Arbitration process). The move-out occurs in the following conditions:

- The first bit of Intermission field
- During Bus Off state when TX Error Counter is in the 124 to 128 range
- During Bus Idle state
- During Wait For Bus Idle state

The move-out process is not atomic. Only the CPU has priority to access the memory concurrently out of Bus Idle state. In Bus Idle, the move-out has the lowest priority to the concurrent memory accesses.
45.4.6 Data coherence

In order to maintain data coherency and FlexCAN proper operation, the CPU must obey the rules described in Transmit process and Receive process.

45.4.6.1 Transmission abort mechanism

The abort mechanism provides a safe way to request the abort of a pending transmission. A feedback mechanism is provided to inform the CPU if the transmission was aborted or if the frame could not be aborted and was transmitted instead.

Two primary conditions must be fulfilled in order to abort a transmission:

- MCR[AEN] must be asserted.
- The first CPU action must be the writing of abort code (0b1001) into the CODE field of the Control and Status word.

Active MBs configured for transmission must be aborted first before they can be updated. If the abort code is written to a Mailbox that is currently being transmitted or to a Mailbox that was already loaded into the Tx SMB for transmission, the write operation is blocked and the transmission is not disturbed. However, the abort request is captured and kept pending until one of the following conditions is satisfied:

- The module loses the bus arbitration.
- There is an error during the transmission.
- The module is put into Freeze mode.
- The module enters Bus Off state.
- There is an overload frame.

If none of the conditions above are reached:

- The MB is transmitted correctly.
- The interrupt flag is set in the IFLAG register.
- An interrupt to the CPU is generated (if enabled).

The abort request is automatically cleared when the interrupt flag is set. On the other hand, if only one of the above conditions is reached, the frame is not transmitted; therefore:

- The abort code is written into the CODE field.
- The interrupt flag is set in the IFLAG.
- An interrupt is (optionally) generated to the CPU.

If the CPU writes the abort code before the transmission begins internally, then the write operation is not blocked; therefore, the MB is updated and the interrupt flag is set. In this way the CPU only needs to read the abort code to make sure the active MB was safely
inactivated. Although the AEN bit is asserted and the CPU wrote the abort code, in this case the MB is inactivated and not aborted, because the transmission did not start yet. One Mailbox is aborted only when the abort request is captured and kept pending until one of the previous conditions is satisfied.

### 45.4.6.2 Mailbox inactivation

Inactivation is a mechanism provided to protect the mailbox against updates by the FlexCAN internal processes, thus allowing the CPU to rely on mailbox data coherence after having updated it, even in Normal mode.

Inactivation of transmission mailboxes must be performed just when MCR[AEN] is deasserted.

If a mailbox is inactivated, it participates in neither the arbitration process nor the matching process until it is reactivated. See Transmit process and Receive process for more detailed instructions on how to inactivate and reactivate a mailbox.

To inactivate a mailbox, the CPU must update its CODE field to INACTIVE (either 0b0000 or 0b1000).

Because you will not be able to synchronize the CODE field update with the FlexCAN internal processes, an inactivation can have the following consequences:

- A frame in the bus that matches the filtering of the inactivated Rx mailbox may be lost without notice, even if there are other mailboxes with the same filter.
- A frame containing the message within the inactivated Tx mailbox may be transmitted without setting the respective IFLAG.

In order to perform a safe inactivation and avoid the above consequences for Tx mailboxes, the CPU must use the transmission abort mechanism (see Transmission abort mechanism).

The inactivation automatically unlocks the mailbox (see Mailbox lock mechanism).

**NOTE**

Message buffers that are part of the Rx FIFO cannot be inactivated. There is no write protection on the FIFO region by FlexCAN. CPU must maintain data coherency in the FIFO region when RFEN is asserted.
45.4.6.3 Mailbox lock mechanism

Other than mailbox inactivation, FlexCAN has another data coherence mechanism for the receive process. When the CPU reads the Control and Status word of an Rx MB with codes FULL or OVERRUN, FlexCAN assumes that the CPU wants to read the whole MB in an atomic operation, and therefore it sets an internal lock flag for that MB. The lock is released when the CPU reads the free running timer (global unlock operation), or when it reads the Control and Status word of another MB regardless of its code. A CPU write into the C/S word also unlocks the MB, but this procedure is not recommended for normal unlock use because it cancels a pending move and potentially may lose a received message. The MB locking prevents a new frame from being written into the MB while the CPU is reading it.

NOTE

The locking mechanism applies only to Rx MBs that are not part of the FIFO and have a code different than INACTIVE (0b0000) or EMPTY\(^1\) (0b0100). Also, Tx MBs cannot be locked.

Suppose, for example, that the FIFO is disabled and the second and the fifth MBs of the array are programmed with the same ID, and FlexCAN has already received and stored messages into these two MBs. Suppose now that the CPU decides to read MB number 5 and at the same time another message with the same ID is arriving. When the CPU reads the Control and Status word of MB number 5, this MB is locked. The new message arrives and the matching algorithm finds out that there are no free-to-receive MBs, so it decides to override MB number 5. However, this MB is locked, so the new message cannot be written there. It will remain in the Rx SMB waiting for the MB to be unlocked, and only then will be written to the MB.

If the MB is not unlocked in time and yet another new message with the same ID arrives, then the new message overwrites the one on the Rx SMB and there will be no indication of lost messages either in the CODE field of the MB or in the Error and Status Register.

While the message is being moved in from the Rx SMB to the MB, the BUSY bit on the CODE field is asserted. If the CPU reads the Control and Status word and finds out that the BUSY bit is set, it should defer accessing the MB until the BUSY bit is negated.

Note

If the BUSY bit is asserted or if the MB is empty, then reading the Control and Status word does not lock the MB.

---

1. In previous FlexCAN versions, reading the C/S word locked the MB even if it was EMPTY. This behavior is maintained when the IRMQ bit is negated.
Inactivation takes precedence over locking. If the CPU inactivates a locked Rx MB, then its lock status is negated and the MB is marked as invalid for the current matching round. Any pending message on the Rx SMB will not be transferred anymore to the MB. An MB is unlocked when the CPU reads the Free Running Timer Register (see Free Running Timer (TIMER)), or the C/S word of another MB.

Lock and unlock mechanisms have the same functionality in both Normal and Freeze modes.

An unlock during Normal or Freeze mode results in the move-in of the pending message. However, the move-in is postponed if an unlock occurs during a low power mode (see Modes of operation), and it takes place only when the module returns to Normal or Freeze modes.

### 45.4.7 Rx FIFO

The Rx FIFO is receive-only and is enabled by asserting MCR[RFEN]. The reset value of this bit is zero to maintain software backward compatibility with previous versions of the module that did not have the FIFO feature.

**CAUTION**

Rx FIFO must not be enabled when CAN FD feature is enabled.

The FIFO is 6-message deep. The memory region occupied by the FIFO structure (both message buffers and FIFO engine) is described in Rx FIFO structure. The CPU can read the received messages sequentially, in the order they were received, by repeatedly reading a message buffer structure at the output of the FIFO.

IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. An interrupt is generated if it is enabled by the corresponding mask bit. Upon receiving the interrupt, the CPU can read the message (accessing the output of the FIFO as a message buffer) and the RXFIR register, and then clear the interrupt. If there are more messages in the FIFO the act of clearing the interrupt updates the output of the FIFO with the next message and updates RXFIR with the attributes of that message, reissuing the interrupt to the CPU. Otherwise, the flag remains negated. The output of the FIFO is valid only while IFLAG1[BUF5I] is asserted.

IFLAG1[BUF6I] (Rx FIFO Warning) is asserted when the number of unread messages within the Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Rx FIFO is almost full. The flag remains asserted until the CPU clears it.
IFLAG1[BUF7I] (Rx FIFO Overflow) is asserted when an incoming message was lost because the Rx FIFO is full. Note that the flag will not be asserted when the Rx FIFO is full and the message was captured by a Mailbox. The flag remains asserted until the CPU clears it.

Clearing one of those three flags does not affect the state of the other two.

An interrupt is generated if an IFLAG bit is asserted and the corresponding mask bit is asserted too.

A powerful filtering scheme is provided to accept only frames intended for the target application, reducing the interrupt servicing workload. The filtering criteria is specified by programming a table of up to 128 32-bit registers, according to CTRL2[RFFN] setting, that can be configured to one of the following formats (see also Rx FIFO structure):

- Format A: 128 IDAFs (extended or standard IDs including IDE and RTR)
- Format B: 256 IDAFs (standard IDs or extended 14-bit ID slices including IDE and RTR)
- Format C: 512 IDAFs (standard or extended 8-bit ID slices)

**Note**
A chosen format is applied to all entries of the filter table. It is not possible to mix formats within the table.

Every frame available in the FIFO has a corresponding IDHIT (Identifier Acceptance Filter Hit Indicator) that can read in the IDHIT field from C/S word, as shown in the Rx FIFO Structure description. Another way the CPU can obtain this information is by accessing the RXFIR register. RXFIR[IDHIT] refers to the message at the output of the FIFO and is valid while the IFLAG1[BUF5I] flag is asserted. The RXFIR register must be read only before clearing the flag, which guarantees that the information refers to the correct frame within the FIFO.

Up to 32 elements of the filter table are individually affected by the Individual Mask Registers (RXIMRx), according to the setting of CTRL2[RFFN], allowing very powerful filtering criteria to be defined. If MCR[IRMQ] is negated, then the FIFO filter table is affected by RXFGMASK.

**NOTE**
For more information about the difference between FD and non-FD regarding this feature, see Table 45-2.
45.4.7.1 Rx FIFO under DMA operation

The receive-only FIFO can support DMA. This feature is enabled by asserting both MCR[RFEN] and MCR[DMA]. The reset value of MCR[DMA] is zero to maintain backward compatibility with previous versions of the module that did not have the DMA feature.

The DMA controller can read the received message by reading a message buffer structure at the FIFO output port at the 0x80-0x8C address range.

When MCR[DMA] is asserted the CPU must not access the FIFO output port address range. Before enabling MCR[DMA], the CPU must service the IFLAGS asserted in the Rx FIFO region. Otherwise, these IFLAGS may show that the FIFO has data to be serviced, and mistakenly generate a DMA request. Before disabling MCR[DMA], the CPU must perform a clear FIFO operation.

IFLAG1[BUF5I] (Frames available in Rx FIFO) is asserted when there is at least one frame available to be read from the FIFO. Consequently a DMA request is generated simultaneously. Upon receiving the request, the DMA controller can read the message (accessing the output of the FIFO as a message buffer). The DMA reading process must end by reading address 0x8C, which clears IFLAG1[BUF5I] and updates both the FIFO output with the next message (if FIFO is not empty) and the RXFIR register with the attributes of the new message. If there are more messages stored in the FIFO, IFLAG1[BUF5I] will be re-asserted and another DMA request is issued. Otherwise, the flag remains negated.

NOTE
RXFIR register contents cannot be read after DMA completes the FIFO read. The IDHIT information is also available in the C/S word at address 0x080 (see Rx FIFO structure.

IFLAG1[BUF6I] and IFLAG1[BUF7I] are not used when the DMA feature is enabled.

When FlexCAN is working with DMA, the CPU does not receive any Rx FIFO interruption and must not clear the related IFLAGS. In addition, the related IMASKs are not used to mask the generation of DMA requests.

NOTE
For more information about the difference between FD and non-FD regarding this feature, see Table 45-2.
45.4.7.2 Clear FIFO operation

When MCR[RFEN] is asserted, the clear FIFO operation is a feature used to empty FIFO contents. With MCR[RFEN] asserted the Clear FIFO occurs when the CPU writes one in IFLAG1[BUF0I]. This operation can only be performed in Freeze mode and is blocked by hardware in other modes. This operation does not clear the FIFO IFLAGs; consequently the CPU must service all FIFO IFLAGs before executing the clear FIFO task.

When Rx FIFO is working with DMA, the clear FIFO operation clears IFLAG1[BUF5I] and the DMA request is canceled.

CAUTION
Clear FIFO operation does not clear IFLAGs, except when MCR[DMA] is asserted; in this case only IFLAG1[BUF5I] is cleared.

45.4.8 CAN protocol related features

This section describes the CAN protocol related features.

45.4.8.1 CAN FD ISO compliance

The CAN FD protocol has been improved to increase the failure detection capability that was in the original CAN FD protocol, which is also called non-ISO CAN FD, by CAN in Automation (CiA). A three-bit stuff counter and a parity bit have been introduced in the improved CAN FD protocol, now called ISO CAN FD. The CRC calculation has also been modified. All these improvements make the ISO CAN FD protocol incompatible with the non-FD CAN FD protocol. The non-ISO CAN FD is still supported by FlexCAN so that it can be used mainly during an intermediate phase, for evaluation and development purposes.

Therefore, it is strongly recommended to configure FlexCAN to the ISO CAN FD protocol by setting the ISOCANFDEN field in the CTRL2 register.

45.4.8.2 CAN FD frames

The ISO 11898-1 standard specifies the Classical Frame format compliant to ISO 11898-1 (2003) and introduces the CAN Flexible Data Rate Frame format. The Classical Frame format allows bit rates up to 1 Mbit/s and payloads up to 8 bytes per frame. The
Flexible Data Rate Frame format allows bit rates higher than 1 Mbit/s and payloads longer than 8 bytes per frame. FlexCAN can receive and transmit CAN FD messages interleaved with Classical CAN messages.

There are three additional control bits in the CAN FD frame. The Extended Data Length (EDL) bit enables a longer data payload with different data length coding. The Bit Rate Switch (BRS) bit decides whether the bit rate is switched inside a CAN FD format frame. The Error State Indicator (ESI) flag is transmitted dominant by error active nodes, and recessive by error passive nodes. There are no Remote Frames (see Remote frames) in the CAN FD format. A message configured to transmit a Remote Frame is always sent out in the Classical CAN format. When an FD frame is received and matches a mailbox, the RTR bit in the receiving message buffer is negated. The RTR bit must be considered in classical frames only.

CAN FD messages may be formatted as long frames where the data field exceeds 8 bytes, and may range from 12 up to 64 bytes. They can also be configured to support bit rate switching, where the control field, the data field, and the CRC field of a CAN frame are transmitted with a higher bit rate than the beginning and the end of the frame. Messages in Classical CAN format are limited to transport a maximum payload of 8 bytes at nominal rate. The following figure illustrates the message formats for Classical and FD frames with either standard or extended ID.
The ability to receive and transmit CAN FD messages is enabled by MCR[FDEN]. Either a recessive R0 bit in CAN frames with 11-bit identifiers or a recessive R1 bit in CAN frames with 29-bit identifiers are decoded as an EDL bit (not a reserved one). A CAN FD frame is recognized by a recessive EDL bit, and a Classical CAN frame is recognized by a dominant EDL bit. The BRS bit specifies whether this frame switches the bit rate in its data phase. A long frame is decoded in accordance with the DLC field value (see DLC definition in Message buffer structure).

CAN FD messages can be transmitted with two different bit rates. The first part of a CAN FD frame, from the Start Of Frame (SOF) bit until the Bit Rate Switch (BRS) bit, also called the arbitration phase, is transmitted with the nominal bit rate based on a set of nominal CAN bit timing configuration values. The second part, from the BRS bit until the CRC Delimiter bit, also named the data phase, is transmitted with the data bit rate.
defined by a second set of CAN data bit timing configuration values. Finally, from the
CRC Delimiter until the Intermission bits, the transmission returns to nominal bit rate. In
CAN FD frames with bit rate switching, the bit timing is changed inside the frame at the
sample point of the BRS bit if this bit is recessive. Before the BRS bit, in the CAN FD
arbitration phase, the nominal CAN bit timing is used as defined by the CBT register
(also by CTRL1 register for backward compatibility). Upon detecting a recessive BRS
bit, the CAN data bit timing is used as defined by the FDCBT register.

**NOTE**

If the length of the time quantum in the nominal bit timing and
the length of the time quantum in the data bit timing are not
identical, a quantization error of up to one time quantum of the
arbitration phase may be present as a phase error. This situation
can occur after the switch from arbitration to data phase and
will last until the next synchronization event. Thus, the length
of the time quantum should be the same in nominal and data bit
timing in order to minimize the chance of error frames on the
CAN bus, and to optimize the clock tolerance in networks that
use FD frames.

FDCTRL[FDRATE] enables the transmission of all frames with bit rate switching if the
BRS bit in the selected Tx MB is set. If FDRATE is negated, the transmission is
performed at nominal rate regardless of the BRS bit value. FDCTRL[FDRATE] can be
written any time but takes effect only for the next message transmitted or received.

The nominal bit timing is resumed at either the sample point of the CRC Delimiter bit or
when an error is detected, whichever occurs first. The following figure describes the
mechanism for entering and leaving the data phase when BRS bit is recessive.
Figure 45-3. Bit rate switching mechanism for CAN FD messages

NOTE
In Classical CAN frames, the CRC delimiter is one single recessive bit. In CAN FD frames, the CRC delimiter may consist of one or two recessive bits. FlexCAN sends only one recessive bit as the CRC delimiter, but it accepts two recessive bits before the edge from recessive to dominant that starts the acknowledge slot. As a receiver, FlexCAN sends its acknowledge bit after the first CRC delimiter bit. In CAN FD frames, FlexCAN accepts a two-bit dominant ACK slot as a valid ACK to compensate for phase shifts between the receivers.
The maximum configurable bit rate in the CAN FD data phase depends on the clock frequency of CAN_PE subblock. For example, with a CAN_PE clock frequency of 40 MHz and the shortest configurable bit time of 5 time quanta, the bit rate in the data phase is 8 Mbit/s.\(^3\)

The value of the ESI bit is determined either by the transmitter's error state at the start of the transmission, if the frame is originated in the FlexCAN node, or by the original transmitting node in case FlexCAN is acting as a gateway for the message. If the transmitter is error passive, ESI is transmitted recessive; otherwise, it is transmitted dominant. The permutations of the relationship between the written value and the transmitted value of the ESI are shown in this table.

</tbody>
</table>

There are different CRC polynomials for different CAN frame formats. The first polynomial, CRC_15, is used for all frames in Classical CAN format. The second, CRC_17, is used for frames in CAN FD format with a data field up to sixteen bytes long. The third, CRC_21, is used for frames in CAN FD format with a data field longer than sixteen bytes. Each polynomial results in a Hamming distance of 6. At the start of the frame, all three CRC polynomials are calculated concurrently. The CRC sequence to be transmitted is selected by the values of the EDL bit and the DLC bit field. When receiving a message, FlexCAN decodes EDL and DLC to select the adequate CRC polynomial to check for a CRC error.

In CAN FD format frames, stuff bits are included in the bit stream for CRC calculation. In Classical CAN format frames, stuff bits are not included. After the transmission of the last bit relevant to the CRC calculation, the FDCRC register stores the calculated CRC for the transmitted message, with the adequate length in accordance to the type of message, for both CAN FD and non-FD messages. The CRCR register reports a valid CRC for Classical CAN messages only.

In CAN FD format frames, the CAN bit stuffing method is changed for the CRC sequence so that the stuff bits are inserted at fixed positions. When FlexCAN is transmitting a CAN FD frame, a fixed stuff bit is inserted just before the first bit of the CRC sequence, even if the last bits of the preceding field do not fulfill the CAN stuff

---

\(^3\) The frequency used in this example may not be supported on this chip; it is shown only to demonstrate how the maximum configurable bit rate is calculated.
condition. Additional stuff bits are inserted after each fourth bit of the CRC sequence. The value of any fixed stuff bit is the inverse value of its preceding bit. When FlexCAN is receiving a CAN FD frame, it discards the fixed stuff bits from the bit stream for the CRC check. A stuff error is detected if the fixed stuff bit has the same value as its preceding bit.

FlexCAN detects errors in CAN FD frames the same way as in Classical CAN frames. The error counters RXERRCNT and TXERRCNT in the ECR register accumulate the counts of Rx and Tx errors, respectively, for both FD and non-FD frames indiscriminately. There are two extra error counters (RXERRCNT_FAST and TXERRCNT_FAST) that accumulate Rx and Tx errors occurring in the data phase of CAN FD frames with the BRS bit set only. The rules for updating the error counters are the same for both CAN FD and non-FD frames (see ECR register).

Error Flags BITERR1, BITERR0, ACKERR, CRCERR, FRMERR, and STFERR in the ESR1 register report errors in both CAN FD and non-FD frames. They also generate the ERRINT interrupt if CTRL1[ERRMSK] is asserted. The ESR1 register has additional error flags (BITERR1_FAST, BITERR0_FAST, CRCERR_FAST, FRMERR_FAST, and STFERR_FAST) to individually indicate the occurrence of errors in the data phase of CAN FD frames with the BRS bit set. There is no ACKERR detected in the data phase of a CAN FD frame. Fault confinement status reported in ESR1[FLTCONF] is the same for both CAN FD and Classical CAN frames, and is based on RXERRCNT and TXERRCNT error counters only. Information contained in RXERRCNT_FAST and TXERRCNT_FAST counters may be considered as status to help detect the error nature related to the bit rate value.

When FlexCAN is in the data phase, either transmitting or receiving a CAN FD message, and detects an error, it immediately switches back to the arbitration phase and to the nominal rate to start an error flag.

Resynchronization and hard synchronization occur in CAN FD frames in the same way as in Classical CAN ones. Additionally, a hard synchronization is also performed at the recessive to dominant edge from EDL to R0 in CAN FD format frames. FlexCAN does not resynchronize while transmitting in the CAN FD data phase.

### 45.4.8.3 Transceiver delay compensation

The CAN FD protocol allows the transmission and reception of data at a higher bit rate than the nominal rate used in the arbitration phase when the message's BRS bit is set. This feature enables the use of rates up to 8 Mbps.
During the data phase of a CAN FD frame, the transmitter detects a bit error if it cannot receive its own latest transmitted bit at the sample point of that bit. When bit rate switching is enabled (BRS bit is asserted), the length of the CAN bit time in the data phase can become shorter than the transceiver's loop delay, thus impeding the correct comparison between the transmitted bit and the received bit within the current CAN bit time interval.

Note that the TDC process defines a secondary sample point where the transmitted bit is correctly compared with the received bit in order to check for bit errors.

The TDC mechanism can be enabled by FDCTRL[TDCEN] and is effective only during the data phase of FD frames having the BRS bit set. It has no effect either on non-FD frames, or on FD frames transmitted at normal bit rate. The TDC is active from the sample point of the BRS bit until the sample point of the CRC Delimiter bit, provided the respective message under transmission has the BRS bit set. When it is active, a comparison is done between the real received bit and the delayed transmitted bit, where the delay is calculated based on the measured transceiver loop delay.

**NOTE**

The actual value of the CRC Delimiter bit is disregarded by transmitters using the transceiver delay compensation mechanism. A global error at the end of the CRC field will cause the receivers to send error frames that the transmitter will detect during Acknowledge or End of Frame.

For every transmitted FD frame having the BRS bit set, the delay measurement is triggered by the transition from the recessive EDL bit to the dominant R0 bit (as shown in the next figure). The loop delay is measured in Protocol Engine (PE) clock periods (CANCLK, see Protocol timing), from the transmitted EDL-R0 edge to the received EDL-R0 edge. The position of the secondary sample point is defined by the measured loop delay time added to an offset value specified in FDCTRL[TDCOFF]. FDCTRL[TDCVAL] stores the result of this calculation. The TDCVAL value saturates at its maximum value of 63 CANCLK when the delay measurement is too long.
The measured loop delay is not enough to be used to define the secondary sample point because it relates to the CAN bit edges. The transceiver delay compensation offset TDCOFF is used to shift the secondary sample point from the edge to an intermediate point inside the bit time, far away from its edges. Therefore, the TDCOFF value cannot be larger than the CAN bit duration in the data phase.

If the secondary sample point is set very near the CAN bit edge (SYNC field), then problems may occur during the bit sampling in the data phase. For the TDC to work reliably, the offset has to use optimal settings. To be sure the bit sampling is performed in the best region, the TDC offset should be configured as shown in this equation:

\[
\text{Offset} = (\text{FPSEG1} + \text{FPROPSEG} + 2) \times (\text{FPRESDIV} + 1)
\]

The following figure shows the SSP position when these settings are used.

During the data phase of CAN FD frames with bit rate switching enabled, at the onset of every Tx CAN bit, the transmitted Tx bit value is temporarily stored in a buffer and a time countdown based on FDCTRL[TDCVAL] is started which ends with the comparison of the received Rx bit (delayed by the external loop delay plus the specified offset) with the stored Tx bit. If a bit error is detected at the secondary sample point, the FlexCAN issues an error flag to the CAN bus at the next sample point.
During the arbitration phase the delay compensation is always disabled. The maximum delay which can be compensated by the FlexCAN's transceiver delay compensation during the data phase is 3 CAN bit times – 2 Tq. Beyond this limit, the FDCTRL[TDCFAIL] flag is set to indicate when the transceiver delay compensation mechanism is out of range, unable to compensate the transceiver loop delay.

### 45.4.8.4 Remote frames

A remote frame is a special kind of frame. You can program a mailbox to be a remote request frame by configuring the mailbox as Transmit with the RTR bit set to one. After the remote request frame is transmitted successfully, the mailbox becomes a receive message buffer, with the same ID as before.

When a remote request frame is received by FlexCAN, it can be treated in three ways, depending on remote request storing (CTRL2[RRS]) and Rx FIFO Enable (MCR[RFEN]):

- If RRS is negated the frame's ID is compared to the IDs of the transmit message buffers with the CODE field 0b1010. If there is a matching ID, then this mailbox frame will be transmitted. Note that if the matching mailbox has the RTR bit set, then FlexCAN will transmit a remote frame as a response. The received remote request frame is not stored in a receive buffer. It is only used to trigger a transmission of a frame in response. The mask registers are not used in remote frame matching, and all ID bits (except RTR) of the incoming received frame should match. In the case that a remote request frame is received and matches a mailbox, this message buffer immediately enters the internal arbitration process, but is considered as a normal Tx mailbox, with no higher priority. The data length of this frame is independent of the DLC field in the remote frame that initiated its transmission.

- If RRS is asserted the frame's ID is compared to the IDs of the receive mailboxes with the CODE field 0b0100, 0b0010, or 0b0110. If there is a matching ID, then this mailbox will store the remote frame in the same fashion of a data frame. No automatic remote response frame will be generated. The mask registers are used in the matching process.

- If RFEN is asserted FlexCAN will not generate an automatic response for remote request frames that match the FIFO filtering criteria. If the remote frame matches one of the target IDs, it will be stored in the FIFO and presented to the CPU. Note that for filtering formats A and B, it is possible to select whether remote frames are accepted or not. For format C, remote frames are always accepted (if they match the ID). Remote request frames are considered as normal frames, and generate a FIFO overflow when a successful reception occurs and the FIFO is already full.
NOTE
There is no remote frame in the CAN FD format. The RTR bit is replaced by a fixed dominant RRS bit. FlexCAN receives and transmits remote frames in the Classical CAN format.

45.4.8.5 Overload frames
FlexCAN does transmit overload frames when the following conditions are detected on the CAN bus:

- Detection of a dominant bit in the first/second bit of Intermission
- Detection of a dominant bit at the 7th bit (last) of End of Frame field (Rx frames)
- Detection of a dominant bit at the 8th bit (last) of Error Frame Delimiter or Overload Frame Delimiter

45.4.8.6 Time stamp
The value of the free running timer is sampled at the beginning of the Identifier field on the CAN bus, and is stored at the end of move-in in the TIME STAMP field, providing network behavior with respect to time.

When CTRL2[TIMER_SRC] is asserted, the free running timer is continuously clocked by an external time tick.

When CTRL2[TIMER_SRC] is negated, the free running timer is clocked by the FlexCAN bit-clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate.

The free running timer is not incremented during Disable, Doze, Stop, and Freeze modes. It can be reset upon a specific frame reception, enabling network time synchronization. See the TSYN description in Control 1 register (CTRL1).
45.4.8.7 Protocol timing

The following figure shows the structure of the clock generation circuitry that feeds the CAN Protocol Engine (PE) submodule. The clock source field CTRL1[CLKSRC] defines whether the internal clock is connected to the output of a crystal oscillator (oscillator clock) or to the peripheral clock. In order to guarantee reliable operation, the clock source should be selected when the module is in Disable mode (MCR[MDIS] is set).

NOTE

Please see the clock distribution chapter (module clocks table) to identify the proper clock source.

![Figure 45-6. CAN engine clocking scheme](image)

The oscillator clock should be selected whenever a tight tolerance (up to 0.1%) is required in the CAN bus timing. The crystal oscillator clock has better jitter performance than the peripheral clock.

The FlexCAN module supports a variety of means to set up bit timing parameters that are required by the CAN protocol. The Control 1 register (CTRL1) has various fields used to control bit timing parameters: PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW.

The CAN Bit Timing register (CBT) extends the range of the CAN bit timing variables in CTRL1. The CAN FD Bit Timing register (FDCBT) provides a second set of CAN bit timing variables to be applied at the data phase of CAN FD frames with the Bit Rate Switch (BRS) set.

NOTE

When the CAN FD feature is enabled, always set CBT[BTF] and configure the CAN bit timing variables in CBT. See CAN Bit Timing register (CBT).

The PRESDIV field (as well as its extended range EPRESDIV and FDPRESDIV for the data phase bits of CAN FD messages) defines the prescaler value (see the equation below) that generates the serial clock (Sclock), whose period defines the time quantum used to compose the CAN waveform. A time quantum (Tq) is the atomic unit of time managed by the CAN engine.
The bit rate, which defines the rate the CAN message is either received or transmitted, is given by the formula:

\[ \text{Bit Rate} = \frac{1}{\text{CAN Bit Time}} \]

\[ \text{CAN Bit Time} = (\text{Number of Time Quanta in 1 bit time}) \times T_q \]

A bit time is subdivided into three segments\(^1\) (see Figure 45-7, Figure 45-8 and Table 45-9):

- **SYNC SEG**: This segment has a fixed length of one time quantum. Signal edges are expected to happen within this section.

- **Time Segment 1**: This segment includes the propagation segment and the phase segment 1 of the CAN standard. It can be programmed by setting \(\text{CTRL1[PROPSEG]}\) and \(\text{CTRL1[PSEG1]}\) so that their sum (plus 2) is in the range of 2 to 16 time quanta. When \(\text{CBT[BTF]}\) is asserted, FlexCAN uses \(\text{EPROPSEG}\) and \(\text{EPSEG1}\) fields from \(\text{CBT}\) register so that their sum (plus 2) is in the range of 2 to 96 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses \(\text{FDPROPSEG}\) and \(\text{FDPSEG1}\) from \(\text{FDCBT}\) instead, so that their sum (plus 1) is in the range of 2 to 39 time quanta.

- **Time Segment 2**: This segment represents the phase segment 2 of the CAN standard. It can be programmed by setting \(\text{CTRL1[PSEG2]}\) (plus 1) to be 2 to 8 time quanta long. When \(\text{CBT[BTF]}\) is asserted, FlexCAN uses \(\text{EPSEG2}\) fields of \(\text{CBT}\) register so that its value (plus 1) is in the range of 2 to 32 time quanta. For messages in CAN FD format with the BRS bit set, FlexCAN uses \(\text{FDPSEG2}\) from \(\text{FDCBT}\) instead, so that its value (plus 1) is in the range of 2 to 8 time quanta. The time segment 2 cannot be smaller than the Information Processing Time (IPT), which value is 2 time quanta in FlexCAN.

**NOTE**

The bit time defined by the above time segments must not be smaller than five time quanta. For bit time calculations, use an Information Processing Time (IPT) of two, which is the value implemented in the FlexCAN module.

---

\(^1\) For further explanation of the underlying concepts, see ISO 11898-1. See also the CAN 2.0A/B protocol specification for bit timing.

Note

The user must ensure the bit time settings are in compliance with the CAN Protocol standard (ISO 11898-1).

Whenever CAN bit is used as a measure of time duration (for example, estimating the occurrence of a CAN bit event in a message), the number of peripheral clocks in one CAN bit (NumClkBit) can be calculated as:

\[
\text{NumClkBit} = \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}} \times (\text{PRESDIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)
\]

where:

- \( \text{NumClkBit} \) is the number of peripheral clocks in one CAN bit.
- \( f_{\text{CANCLK}} \) is the Protocol Engine (PE) Clock (see Figure 45-6), in Hz.
- \( f_{\text{SYS}} \) is the frequency of operation of the system (CHI) clock, in Hz.
- \( \text{PSEG1} \) is the value in CTRL1[PSEG1] field.
- \( \text{PSEG2} \) is the value in CTRL1[PSEG2] field.
- \( \text{PROPSEG} \) is the value in CTRL1[PROPSEG] field.
- \( \text{PRESDIV} \) is the value in CTRL1[PRESDIV] field.

The formula above is also applicable to the alternative CAN bit timing variables described in the CAN Bit Timing register (CBT) and also to the CAN FD Bit Timing register (FDCBT).

For example, 180 CAN bits = (180 x NumClkBit) peripheral clock periods.

45.4.8.8 Arbitration and matching timing

During normal reception and transmission, the matching, arbitration, move-in, and move-out processes are executed during certain time windows inside the CAN frame, as shown in the following figures.
NOTE
In the preceding figures, the matching and arbitration timing does not take into account the delay caused by the concurrent memory access due to the CPU or other internal FlexCAN subblocks.

45.4.8.9  Tx arbitration start delay
CTRL2[TASD] (Tx Arbitration Start Delay) is a variable that indicates the number of CAN bits used by FlexCAN to delay the Tx arbitration process start point from the first bit of CRC field of the current frame. This variable can be written only in Freeze mode because it is blocked by hardware in other modes.

The transmission performance is impacted by the ability of the CPU to reconfigure message buffers (MBs) for transmission after the end of the internal arbitration process, where FlexCAN finds the winner MB for transmission (see Arbitration process). If the
arbitration ends too early before the first bit of Intermission field, then there is a chance that the CPU reconfigures some Tx MBs and the winner MB is no longer the best candidate to be transmitted.

TASD is useful to optimize the transmission performance by defining the arbitration start point, as shown in the next figure, based on factors such as:

- Peripheral-to-oscillator clock ratio
- CAN bit timing variables that determine the CAN bit rate
- Number of message buffers (MBs) in use by the matching and arbitration processes

![Diagram of arbitration process](image)

**Figure 45-12. Optimal Tx Arbitration start point**

The duration of an arbitration process, in terms of CAN bits, is directly proportional to the number of available MBs and to the CAN bit rate, and inversely proportional to the peripheral clock frequency.

The optimal arbitration timing is that in which the last MB is scanned just before the first bit of the Intermission field of a CAN frame. For instance, if there are few MBs and the peripheral/oscillator clock ratio is high and the CAN baud rate is low, then the arbitration can be placed closer to the frame's end, adding more delay to its start point, and vice-versa.

If TASD is set to 0 then the arbitration start is not delayed and more time is reserved for arbitration. On the other hand, if TASD is close to 24 then the CPU can configure a Tx MB later and less time is reserved for arbitration. If too little time is reserved for arbitration the FlexCAN may be not be able to find a winner MB in time to be transmitted with the best chance to win the bus arbitration against external nodes on the CAN bus.

The optimal TASD value can be calculated as follows:
For CAN FD frames and \((\text{MAXMB} + 1) \leq \text{NMB}_{\text{END}}\)

\[
\text{TASD} = 31 - \frac{2 \times (\text{MAXMB} + 1) + 4}{\text{CPCB}_N}
\]

For CAN FD frames and \((\text{MAXMB} + 1) > \text{NMB}_{\text{END}}\)

\[
\text{TASD} = 22 - \frac{2 \times (\text{MAXMB} + 1) - \text{NMB}_{\text{END}}}{\text{CPCB}_F}
\]

For non-FD frames

\[
\text{TASD} = 25 - \frac{2 \times (\text{MAXMB} + 1) + 4}{\text{CPCB}}
\]

where:

\[
\text{NMB}_{\text{END}} = \frac{(9 \times \text{CPCB}_N) - 4}{2}
\]

\[
\text{BITRATE}_N = \left( \frac{\text{f}_{\text{CANCLK}}}{[1 + (\text{EPSEG1} + 1) + (\text{EPSEG2} + 1) + (\text{EPROPSEG} + 1)] \times (\text{EPRESDIV} + 1)} \right)
\]

\[
\text{BITRATE}_F = \left( \frac{\text{f}_{\text{CANCLK}}}{[1 + (\text{FPSEG1} + 1) + (\text{FPSEG2} + 1) + \text{FPROPSEG}] \times (\text{FPRESDIV} + 1)} \right)
\]

\[
\text{CPCB}_N = \frac{\text{f}_{\text{SYS}}}{\text{BITRATE}_N}
\]

\[
\text{CPCB}_F = \frac{\text{f}_{\text{SYS}}}{\text{BITRATE}_F}
\]

\[
\text{CPCB} = \text{CPCB}_N
\]

- MAXMB is the value in \text{CTRL1}[MAXMB].
- \text{NMB}_{\text{END}} is the number of message buffers that can be scanned by the arbitration process during the 9 last CAN bits at the end of a frame (see the figure above).
- \text{BITRATE}_N is the CAN bit rate in bits per second calculated by the nominal CAN bit time variables.
- \text{BITRATE}_F is the CAN bit rate in bits per second calculated by the data CAN bit time variables.
- \text{CPCB}_N is the number of peripheral clocks per CAN bit in nominal bit rate for CAN FD frames.
- \text{CPCB}_F is the number of peripheral clocks per CAN bit in data bit rate for CAN FD frames.
- CPCB is the number of peripheral clocks per CAN bit for non-FD frames.
- \text{f}_{\text{CANCLK}} is the oscillator clock, in Hz.
- \text{f}_{\text{SYS}} is the peripheral clock, in Hz.
- \text{EPSEG1} is the value in \text{CBT}[\text{EPSEG1}] (\text{CTRL1}[\text{PSEG1}] can also be used).
- \text{EPSEG2} is the value in \text{CBT}[\text{EPSEG2}] (\text{CTRL1}[\text{PSEG2}] can also be used).
• EPROPSEG is the value in CBT[EPROPSEG] (CTRL1[PROPSEG] can also be used).
• EPRESDIV is the value in CBT[EPRESDIV] (CTRL1[PRESDIV] can also be used).
• FPSEG1 is the value in FDCBT[FPSEG1].
• FPSEG2 is the value in FDCBT[FPSEG2].
• FPROPSEG is the value in FDCBT[FPROPSEG].
• FPRESDIV is the value in FDCBT[FPRESDIV].

See also Protocol timing for more details.

The following tables give the TASD value calculated for some configuration cases.

Case 1:
• Clock ratio = 2:1 (example: peripheral clock 80 MHz and oscillator clock 40 MHz)
• Bit rate in arbitration phase = 1 Mbaud

45.4.9 Clock domains and restrictions

The FlexCAN module has two clock domains asynchronous to each other:

- The bus domain feeds the Control Host Interface (CHI) submodule and is derived from the peripheral clock.
- The oscillator domain feeds the CAN Protocol Engine (PE) submodule and is derived directly from a crystal oscillator clock, so that very low jitter performance can be achieved on the CAN bus.

When CTRL1[CLKSRC] is set, synchronous operation occurs because both domains are connected to the peripheral clock (creating a 1:1 ratio between the peripheral and oscillator clocks).

When the two domains are connected to clocks with different frequencies and/or phases, there are restrictions on the frequency relationship between the two clock domains. In the case of asynchronous operation, the bus domain clock frequency must always be greater than the oscillator domain clock frequency.

NOTE
Asynchronous operation with a 1:1 ratio between peripheral and oscillator clocks is not allowed.

When doing matching and arbitration, FlexCAN needs to scan the whole message buffer memory during the time slot of one CAN frame, comprised of a number of CAN bits. In order to have sufficient time to do that, the following requirements must be observed:

- The peripheral clock frequency cannot be smaller than the oscillator clock frequency.
- There must be a minimum number of peripheral clocks per CAN bit, as specified in the table shown below.
### Table 45-14. Minimum number of peripheral clocks per CAN bit for Classical CAN format

<table>
<thead>
<tr>
<th>Number of mailboxes</th>

<td>30</td>
</tr>
</tbody>
</table>

For classical frame format, the minimum number of peripheral clocks per CAN bit specified in the preceding table determines the minimum peripheral clock frequency for a given number of mailboxes and for an expected CAN bit rate. The CAN bit rate depends on the number of time quanta in a CAN bit, which can be defined by adjusting one or more of the bit timing values contained in either the Control 1 register (CTRL1) or CAN Bit Time register (CBT). The time quantum (Tq) is defined in Protocol timing. The minimum number of time quanta per CAN bit must be 8; therefore, the oscillator clock frequency should be at least 8 times the CAN bit rate.

For CAN FD frame format, there are some constraints that need to be satisfied. The number of peripheral clocks per CAN bit in nominal bit rate (NumClkNomBit) can be calculated by the equation below.

\[
\text{NumClkNomBit} = \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}} \times (\text{PRESDIV} + 1) \times (\text{PROPSEG} + \text{PSEG1} + \text{PSEG2} + 4)
\]

where PRESDIV, PSEG1, and PSEG2 are CAN bit time values in CTRL1 register. Alternatively, EPRESDIV, EPSEG1, and EPSEG2 values in CBT register can be used instead. NumClkNomBit can also be calculated as a function of the expected nominal bit rate used in the arbitration phase (NomBitRate), as shown in the equation above.

The number of CAN bits in the data phase of an FD frame with the BRS bit set (fast CAN bits, in short) depends on the number of data bytes in the payload. The number of fast CAN bits (NumOfFastBits) can be determined in the table below. The fewer the number of data bytes, the fewer the number of fast CAN bits, and less time is available for FlexCAN to scan the whole message buffer memory during the internal matching and arbitration processes.
Table 45-15. Number of fast CAN bits in a CAN FD frame

</tr>
</tbody>
</table>

The critical part of a CAN FD frame is during the data phase, where the CAN bit rate is faster than in the arbitration phase. The minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) can be calculated to guarantee that enough time is available for FlexCAN to scan the message buffer memory during reception and transmission. The equation below calculates this constraint.

\[
\text{MinNumClkFastBit}_A = \frac{(8.5 \times \text{MaxNumOfMb}) + 64 - (9 \times \text{NumClkNomBit})}{\text{NumOfFastBits}}
\]

where MaxNumOfMb is the maximum number of available mailboxes defined in MCR[MAXMB].

The clock domain crossing circuit between the CHI and PE subblocks also imposes a minimum number of peripheral clocks per fast CAN bit for the handshake mechanism to work properly without losing status information through the interface, as shown in the equation below.

\[
\text{MinNumClkFastBit}_B = 3 \times \left(1 + \frac{f_{\text{SYS}}}{f_{\text{CANCLK}}}\right)
\]

Therefore, the minimum number of peripheral clocks per fast CAN bit (MinNumClkFastBit) is determined by the larger of the two values calculated above.
Then, the maximum CAN bit rate in the data phase of CAN FD frames (\(\text{DataBitRateMAX}\)) can be calculated as below.

\[
\text{DataBitrate}_{\text{MAX}} = \frac{f_{\text{CANCLK}}}{\text{ROUNDUP} \left( \frac{\text{MinNumClkFastBit} \times f_{\text{CANCLK}}}{f_{\text{SYS}}} \right)}
\]

The peripheral and oscillator clock frequencies, the maximum number of mailboxes, and the expected nominal bit rate affect the maximum data bit rate attainable by FlexCAN in CAN FD mode. Also, the data bit rate depends on the minimum payload size of FD frames used in a given application.

To illustrate how the CAN FD bit rate is affected by the configuration of FlexCAN variables, an application example with the peripheral and oscillator clock frequencies set to 50 MHz and 40 MHz, respectively, is considered.

1. Considering the nominal bit rate as 1 Mbps, the number of peripheral clocks per CAN bit in nominal bit rate is calculated as below.

\[
\text{NumClkNomBit} = \frac{50 \times 10^6}{1 \times 10^6} = 50
\]

2. The number of fast CAN bits (\(\text{NumOfFastBits}\)) is determined in the table presented above. For example, if the minimum payload in FD frames is 8 bytes, then there are 85 CAN bits in the data phase.

3. Assuming the maximum number of mailboxes is 96, the minimum number of peripheral clocks per fast CAN bit (\(\text{MinNumClkFastBit}\)) can be calculated.

\[
\text{MinNumClkFastBit}_A = \frac{(8.5 \times 96) + 64 - (9 \times 50)}{85} = 5.06
\]

\[
\text{MinNumClkFastBit}_B = 3 \times \left( 1 + \frac{50}{40} \right) = 6.75
\]

\[
\text{MinNumClkFastBit} = \text{Maximum} (5.06, 6.75) = 6.75
\]

4. The maximum CAN bit rate in the data phase can finally be found.

\[
\text{DataBitRate}_{\text{MAX}} = \frac{40 \times 10^6}{\text{ROUNDUP} \left( \frac{6.75 \times 40 \times 10^6}{50 \times 10^6} \right)} = 6.667 \text{ Mbps}
\]
As demonstrated in this example, even though the oscillator clock frequency (40 MHz) is adequate to generate a data rate of 8 Mbps in CAN FD mode, the specific FlexCAN configuration limits this rate to 6.667 Mbps. This limitation is mainly due to the low peripheral clock frequency that imposes the MinNumClkFastBitB bound.

The table below shows the maximum data rate for CAN FD according to clock frequencies, payload size, and number of available mailboxes. See in this table that, for some cases, if the number of available mailboxes is reduced, the FlexCAN can then achieve a data rate up to 8 Mbps.

**45.4.10 Modes of operation details**

The FlexCAN module has functional modes and low-power modes. See *Modes of operation* for an introductory description of all the modes of operation. The following sub-sections contain functional details on Freeze mode and the low-power modes.

**CAUTION**

"Permanent Dominant" failure on CAN Bus line is not supported by FlexCAN. If a Low-Power request or Freeze mode request is done during a "Permanent Dominant", the corresponding acknowledge can never be asserted.
Freeze mode

This mode is requested either by the CPU through the assertion of MCR[HALT] or when the chip is put into Debug mode. In both cases it is also necessary that MCR[FRZ] be asserted and the module not be in a low-power mode.

The acknowledgement is obtained through the assertion by the FlexCAN of MECR[FRZ_ACK]. The CPU must only consider the FlexCAN in Freeze mode when both request and acknowledgement conditions are satisfied.

When Freeze mode is requested, FlexCAN does the following:

- Waits to be in either Intermission, Passive Error, Bus Off, or Idle state.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in does not prevent entering Freeze mode.
- Ignores the Rx input pin and drives the Tx pin as recessive.
- Stops the prescaler, thus halting all CAN protocol activities.
- Grants write access to the Error Counters register, which is read-only in other modes.
- Sets MCR[NOTRDY] and MCR[FRZACK].

After requesting Freeze mode, the user must wait for MCR[FRZ_ACK] to be asserted before executing any other action; otherwise FlexCAN may operate in an unpredictable way. In Freeze mode, all memory-mapped registers are accessible, except for CTRL1[CLKSRC], which can be read but cannot be written.

Exiting Freeze mode is done in one of the following ways:

- CPU negates MCR[FRZ].
- The chip is removed from Debug mode and/or the HALT bit is negated.

MCR[FRZ_ACK] is negated after the protocol engine recognizes the negation of the freeze request. When out of Freeze mode, FlexCAN tries to resynchronize to the CAN bus by waiting for 11 consecutive recessive bits.
45.4.10.2 Module Disable mode

This low-power mode is normally used to temporarily disable a complete FlexCAN block, with no power consumption. It is requested by the CPU through the assertion of MCR[MDIS], and the acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN in Disable mode when both request and acknowledgement conditions are satisfied.

If the module is disabled during Freeze mode, it requests to disable the clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates MCR[FRZACK].

If the module is disabled during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and then checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14 Mask register, the Rx Buffer 15 Mask register, the Rx FIFO Global Mask register. The Rx FIFO Information register, the message buffers, the Rx Individual Mask registers, and the reserved words within RAM may not be accessed when the module is in Disable mode. Exiting from this mode is done by negating the MDIS bit by the CPU, which causes the FlexCAN to request to resume the clocks and negate the LPMACK bit after the CAN protocol engine recognizes the negation of disable mode requested by the CPU.

45.4.10.3 Doze mode

This is a system low power mode in which the CPU bus is kept alive and a global Doze mode request is sent to all peripherals asking them to enter low-power mode. When Doze mode is globally requested, MCR[DOZE] needs to have been asserted previously for Doze mode to be triggered. The acknowledgement is obtained through the assertion by the FlexCAN of MCR[LPMACK]. The CPU must only consider the FlexCAN to be in Doze mode when both request and acknowledgement conditions are satisfied.
If Doze mode is triggered during Freeze mode, FlexCAN requests to shut down the
clocks to the PE and CHI submodules, sets MCR[LPMACK] and negates
MCR[FRZACK]. If Doze mode is triggered during transmission or reception, FlexCAN
does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of
  Intermission and checks it to be recessive.
- Waits for all internal activities like arbitration, matching, move-in, and move-out to
  finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive.
- Shuts down the clocks to the PE and CHI submodules.
- Sets MCR[NOTRDY] and MCR[LPMACK].

The Bus Interface Unit continues to operate, enabling the CPU to access memory-
mapped registers, except the Rx Mailboxes Global Mask registers, the Rx Buffer 14
Mask register, the Rx Buffer 15 Mask register, the Rx FIFO Global Mask register. The
Rx FIFO Information register, the message buffers, the Rx Individual Mask registers, and
the reserved words within RAM may not be accessed when the module is in Doze mode.

Exiting Doze mode is done in one of the following ways:

- CPU removing the Doze mode request
- CPU negating MCR [DOZE]
- Self Wake mechanism

In the Self Wake mechanism, if MCR[SLFWAK] was set at the time FlexCAN entered
Doze mode, then upon detection of a recessive to dominant transition on the CAN bus,
FlexCAN negates the DOZE bit, requests to resume its clocks and negates the LPMACK
after the CAN protocol engine recognizes the negation of the Doze mode request. It also
sets ESR [WAKINT] and, if enabled by MCR[WAKMSK], generates a Wake-Up
interrupt to the CPU. FlexCAN will then wait for 11 consecutive recessive bits to
synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it
up. The following table details the effect of SLFWAK and WAKMSK upon wakeup from
Doze mode.

<table>

</table>

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line when in Doze mode. (See MCR[WAKSRC].) This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

### 45.4.10.4 Stop mode

This is a system low-power mode in which all chip clocks can be stopped for maximum power savings. The Stop mode is globally requested by the CPU and acknowledgement is obtained through the assertion by the FlexCAN of a Stop Acknowledgement signal. The CPU must only consider the FlexCAN in Stop mode when both request and acknowledgement conditions are satisfied.

If FlexCAN receives the global Stop mode request during Freeze mode, it sets MCR[LPMACK], negates MCR[FRZACK], and then sends the Stop Acknowledge signal to the CPU, in order to shut down the clocks globally.

If Stop mode is requested during transmission or reception, FlexCAN does the following:

- Waits to be in either Idle or Bus Off state, or else waits for the third bit of Intermission and checks it to be recessive
- Waits for all internal activities like arbitration, matching, move-in, and move-out to finish. A pending move-in is not taken into account.
- Ignores its Rx input pin and drives its Tx pin as recessive
- Sets MCR[NOTRDY] and MCR[LPMACK]
- Sends a Stop Acknowledge signal to the CPU, so that it can shut down the clocks globally

Stop mode is exited when the CPU resumes the clocks and removes the Stop mode request. This can be as a result of the Self Wake mechanism.
In the Self Wake mechanism, if MCR[SLFWAK] was set at the time FlexCAN entered Stop mode, then upon detection of a recessive to dominant transition on the CAN bus, FlexCAN sets ESR[WAKINT] and, if enabled by MCR[WAKMSK], generates a Wake Up interrupt to the CPU. Upon receiving the interrupt, the CPU should resume the clocks and remove the Stop mode request. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up. The following table details the effect of MCR[SLFWAK] and MCR[WAKMSK] upon wakeup from Stop mode. Note that wakeup from Stop mode only works when both bits are asserted.

After the CAN protocol engine recognizes the negation of the Stop mode request, the FlexCAN negates MCR[LPMACK]. FlexCAN will then wait for 11 consecutive recessive bits to synchronize to the CAN bus. As a consequence, it will not receive the frame that woke it up.

</table>

The sensitivity to CAN bus activity can be modified by applying a low-pass filter function to the Rx CAN input line when in Stop mode. (See the description in MCR[WAKSRC].) This feature can be used to protect FlexCAN from waking up due to short glitches on the CAN bus lines. Such glitches can result from electromagnetic interference within noisy environments.

### 45.4.11 Interrupts

The module has many interrupt sources: interrupts due to message buffers and interrupts due to the ORed interrupts from MBs, Bus Off, Bus Off Done, Error, Error Fast (errors detected in the data phase of CAN FD format messages with the BRS bit set), Wake Up, Tx Warning, and Rx Warning.

Each one of the message buffers can be an interrupt source, if its corresponding IMASK bit is set. There is no distinction between Tx and Rx interrupts for a particular buffer, under the assumption that the buffer is initialized for either transmission or reception.
Each of the buffers has an assigned flag bit in the IFLAG registers. The bit is set when the corresponding buffer completes a successful transfer and is cleared when the CPU writes one to it (unless another interrupt is generated at the same time).

**Note**

It must be guaranteed that the CPU clears only the bit causing the current interrupt. For this reason, bit manipulation instructions (BSET) must not be used to clear interrupt flags. These instructions may cause accidental clearing of interrupt flags which are set after entering the current interrupt service routine.

If the Rx FIFO is enabled (MCR[RFEN] = 1) and DMA is disabled (MCR[DMA] = 0), the interrupts corresponding to MBs 0 to 7 have different meanings. Bit 7 of the IFLAG1 register becomes the "FIFO Overflow" flag; bit 6 becomes the "FIFO Warning" flag, bit 5 becomes the "Frames Available in FIFO" flag and bits 4-0 are unused. See the description of **Interrupt Flags 1 register (IFLAG1)** for more information.

If both Rx FIFO and DMA are enabled (MCR[RFEN] and MCR[DMA] = 1) the FlexCAN does not generate any FIFO interrupt. Bit 5 of the IFLAG1 register still indicates "Frames Available in FIFO" and generates a DMA request. Bits 7, 6, 4-0 are unused.

**CAUTION**

FIFO cannot be enabled when CAN FD feature is enabled.

For a combined interrupt where multiple MB interrupt sources are OR'd together, the interrupt is generated when any of the associated MBs (or FIFO, if applicable) generates an interrupt. In this case, the CPU must read the IFLAG registers to determine which MB or FIFO source caused the interrupt.

The following interrupt sources generate interrupts like the MB interrupt sources, and can be read from ESR1 register

- Bus Off
- Bus Off Done
- Error
- Error Fast
- Wake Up
- Tx Warning
- Rx Warning

The Bus Off, Error, Tx Warning, and Rx Warning interrupt mask bits are located in the CTRL1 register; the Wake-Up interrupt mask bit is located in MCR.
45.4.12  Bus interface

CPU access to FlexCAN registers is subject to the following rules:

- Unrestricted read and write access to supervisor registers (registers identified with S/U in Table 45-19 in Supervisor Mode or with S only) results in an access error.
- Read and write access to implemented reserved address space results in an access error.
- Write access to positions whose bits are all currently read-only results in an access error. If at least one of the bits is not read-only then no access error is issued. Write permission to positions or some of their bits can change depending on the mode of operation or transitory state. See register and field descriptions for details.
- Read and write access to unimplemented address space results in an access error.
- Read and write access to RAM located positions during Low Power mode results in an access error.
- It is possible for the RXIMR memory region to be considered as general purpose memory and available for access. There are two ways of doing this:
  a. If MCR[IRMQ] is cleared, the individual masks (RXIMR) are disabled. In this case the RXIMR memory region is considered as general purpose memory.
  b. If MCR[MAXMB] is programmed with a value smaller than the available number of MBs, then the unused memory space can be used as general purpose RAM space. Note that reserved words within RAM cannot be used. As an example, suppose FlexCAN's RAM can support up to 16 MBs, CTRL2[RFFN] is 0x0, and MCR[MAXMB] is programmed with zero. The maximum number of MBs in this case becomes one. The RAM starts at 0x0080, and the space from 0x0080 to 0x008F is used by the one MB. The memory space from 0x0090 to 0x017F is available. The space between 0x0180 and 0x087F is reserved. The space from 0x0880 to 0x0883 is used by the one individual mask and the available memory in the mask registers space would be from 0x0884 to 0x08BF. From 0x08C0 through 0x09DF there are reserved words for internal use which cannot be used as general purpose RAM. As a general rule, free memory space for general purpose depends only on MAXMB.
  c. If MCR[FDEN] is enabled, general purpose memory can be used out of Freeze mode only.

45.5  Initialization/application information

This section provides instructions for initializing the FlexCAN module.
45.5.1 FlexCAN initialization sequence

The FlexCAN module may be reset in three ways:

1. Chip level hard reset, which resets all memory-mapped registers asynchronously.
2. MCR[SOFTRST], which resets some of the memory-mapped registers synchronously. See Table 45-19 to see what registers are affected by soft reset.
3. Chip level soft reset, which has the same effect as MCR[SOFTRST].

Soft reset is synchronous and has to follow an internal request/acknowledge procedure across clock domains. Therefore, it may take some time to fully propagate its effects. MCR[SOFTRST] remains asserted while soft reset is pending, so software can poll this bit to know when the reset has completed. Also, soft reset cannot be applied while clocks are shut down in a low-power mode. The low-power mode should be exited and the clocks resumed before applying soft reset.

The clock source should be selected when the module is in Disable mode (see CTRL1[CLKSRC] description in Control 1 register (CTRL1)). After the clock source is selected and the module is enabled (MCR[MDIS] bit negated), FlexCAN automatically enters Freeze mode. In Freeze mode, FlexCAN is un-synchronized to the CAN bus, MCR[HALT] and MCR[FRZ] are set, the internal state machines are disabled, then MCR[FRZACK] and MCR[NOTRDY] are set. The Tx pin is in recessive state and FlexCAN does not initiate any transmission or reception of CAN frames. Note that the message buffers and the Rx Individual Mask registers are not affected by reset, so they are not automatically initialized.

For any configuration change/initialization it is required that FlexCAN be put into Freeze mode (see Freeze mode). The following is a generic initialization sequence applicable to the FlexCAN module:

1. Initialize the Module Configuration register (MCR).
   a. Enable the individual filtering per MB and reception queue features by setting IRMQ.
   b. Enable the warning interrupts by setting WRNEN.
   c. If required, disable frame self reception by setting SRXDIS.
   d. Enable the Rx FIFO by setting RFEN.
   e. If Rx FIFO is enabled and DMA is required, set DMA.
   f. Enable the abort mechanism by setting AEN.
   g. Enable the local priority feature by setting LPRIOEN.
2. Initialize the Control 1 register (CTRL1) and optionally the CAN Bit Timing register (CBT). Initialize also the CAN FD CAN Bit Timing register (FDCBT).
   a. Determine the bit timing parameters: PROPSEG, PSEG1, PSEG2, and RJW.
b. Optionally determine the bit timing parameters: EPROPSEG, EPSEG1, EPSEG2, and ERJW.
c. Determine the CAN FD bit timing parameters: FPROPSEG, FPSEG1, FPSEG2, and FRJW.
d. Determine the bit rate by programming the PRESDIV field and optionally the EPRESDIV field.
e. Determine the CAN FD bit rate by programming the FPRESDIV field.
f. Determine the internal arbitration mode (LBUF).

3. Initialize the message buffers.
   a. The control and status word of all message buffers must be initialized.
   b. If Rx FIFO was enabled, the ID filter table must be initialized.
   c. Other entries in each message buffer should be initialized as required.

4. Initialize the Rx Individual Mask registers (RXIMRn).

5. Set required interrupt mask bits in
   • IMASK registers (for all MB interrupts)
   • MCR register (for Wake-Up interrupt)
   • CTRL1 / CTRL2 registers (for Bus Off and Error interrupts)

6. Negate MCR[HALT].

After the last step listed above, FlexCAN attempts to synchronize to the CAN bus.

### 45.6 Memory map/register definition

This section describes the registers and data structures in the FlexCAN module. The base address of the module depends on the particular memory map of the chip.

#### 45.6.1 FlexCAN memory mapping

The memory map for the FlexCAN module is shown in the following table.

The address space occupied by FlexCAN has 128 bytes for registers starting at the module base address, followed by embedded RAM starting at address offset 0x0080.

Each individual register is identified by its complete name and the corresponding mnemonic. The access type can be Supervisor (S) or Unrestricted (U). Most of the registers can be configured to have either Supervisor or Unrestricted access by programming MCR[SUPV]. These registers are identified as S/U in the Access column of Table 45-19.
NOTE
An invalid register access will result in a bus error. This includes reading a write-only register, writing a read-only register, or accessing an invalid address.

The FlexCAN module can store CAN messages for transmission and reception using mailboxes and Rx FIFO structures.

45.6.2 CAN register descriptions

The table below shows the FlexCAN memory map.
The address range from offset 0x80 to 0x47F allocates the sixty-four 128-bit message buffers (MBs).

The memory maps for the message buffers are in FlexCAN message buffer memory map.

| 31 MDIS | Module Disable  
  This bit controls whether FlexCAN is enabled or not. When disabled, FlexCAN disables the clocks to the CAN Protocol Engine and Controller Host Interface submodules. This bit is not affected by soft reset.  
  0b - Enable the FlexCAN module.  
  1b - Disable the FlexCAN module.  |
| 30 FRZ | Freeze Enable  
  The FRZ bit specifies the FlexCAN behavior when MCR[HALT] is set or when Debug mode is requested at chip level. When FRZ is asserted, FlexCAN is enabled to enter Freeze mode. Negation of this bit field causes FlexCAN to exit from Freeze mode.  
  0b - Not enabled to enter Freeze mode.  
  1b - Enabled to enter Freeze mode.  |
| 29 RFEN | Rx FIFO Enable  |

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>This bit controls whether the Rx FIFO feature is enabled or not. When RFEN is set, MBs 0 to 5 cannot be used for normal reception and transmission because the corresponding memory region (0x80-0xDC) is used by the FIFO engine as well as additional MBs (up to 32, depending on CTRL2[RFFN] setting) which are used as Rx FIFO ID filter table elements. RFEN also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 45-14. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes.</td>
<td></td>
</tr>
<tr>
<td>NOTE: This bit cannot be set when CAN FD operation is enabled (see FDEN bit).</td>

</tr>
<tr>
<td>23</td>
<td>Supervisor Mode</td>
</tr>
</tbody>
</table>

Table continues on the next page...
### Field | Function
---|---
**SUPV** | This bit configures the FlexCAN to be either in Supervisor or User mode. The registers affected by this bit are marked as S/U in the "Access type" column of Table 45-19. Reset value of this bit is 1, so the affected registers start with Supervisor access allowance only. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  
0b - FlexCAN is in User mode. Affected registers allow both Supervisor and Unrestricted accesses.  
1b - FlexCAN is in Supervisor mode. Affected registers allow only Supervisor access. Unrestricted access behaves as though the access was done to an unimplemented register location.  

22 | Self Wake Up  
SLFWAK | This feature enables the Self Wake Up feature when FlexCAN is in a low-power mode other than Disable mode. When this feature is enabled, the FlexCAN module monitors the bus for wakeup event, that is, a recessive-to-dominant transition.  
If a wakeup event is detected during Doze mode, FlexCAN requests to resume its clocks and, if enabled to do so, generates a Wake Up interrupt to the CPU.  
If a wakeup event is detected during Stop mode, then FlexCAN generates, if enabled to do so, a Wake Up interrupt to the CPU so that it can exit Stop mode globally and FlexCAN can request to resume the clocks.  
When FlexCAN is in a low-power mode other than Disable mode, this bit cannot be written as it is blocked by hardware.  
0b - FlexCAN Self Wake Up feature is disabled.  
1b - FlexCAN Self Wake Up feature is enabled.  

21 | Warning Interrupt Enable  
WRNEN | When asserted, this bit enables the generation of the TWRNINT and RWRNINT flags in the Error and Status Register 1 (ESR1). If WRNEN is negated, the TWRNINT and RWRNINT flags will always be zero, independent of the values of the error counters, and no warning interrupt will ever be generated. This bit can be written in Freeze mode only, because it is blocked by hardware in other modes.  
0b - TWRNINT and RWRNINT bits are zero, independent of the values in the error counters.  
1b - TWRNINT and RWRNINT bits are set when the respective error counter transitions from less than 96 to greater than or equal to 96.  

20 | Low-Power Mode Acknowledge  
LPMACK | This read-only bit indicates that FlexCAN is in a low-power mode (Disable mode, Doze mode, Stop mode). A low-power mode cannot be entered until all current transmission or reception processes have finished, so the CPU can poll the LPMACK bit to know when FlexCAN has actually entered low power mode. This bit is not affected by soft reset.  
**NOTE:** LPMACK will be asserted within 180 CAN bits from the low-power mode request by the CPU, and negated within 2 CAN bits after the low-power mode request removal (see Protocol timing).  
0b - FlexCAN is not in a low-power mode.  
1b - FlexCAN is in a low-power mode.  

19 | Wake Up Source  
WAKSRC | This bit defines whether the integrated low-pass filter is applied to protect the Rx CAN input from spurious wakeup. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  
0b - FlexCAN uses the unfiltered Rx input to detect recessive to dominant edges on the CAN bus.  
1b - FlexCAN uses the filtered Rx input to detect recessive to dominant edges on the CAN bus.  

18 | Doze Mode Enable  
DOZE | This bit defines whether FlexCAN is allowed to enter low-power mode when Doze mode is requested at chip level. This bit is automatically reset when FlexCAN wakes up from Doze mode upon detecting activity on the CAN bus (self wakeup enabled).  
0b - FlexCAN is not enabled to enter low-power mode when Doze mode is requested.  
1b - FlexCAN is enabled to enter low-power mode when Doze mode is requested.  

17 | Self Reception Disable

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| SRXDIS | This bit defines whether FlexCAN is allowed to receive frames transmitted by itself. If this bit is asserted, frames transmitted by the module will not be stored in any MB, regardless if the MB is programmed with an ID that matches the transmitted frame, and no interrupt flag or interrupt signal will be generated due to the frame reception. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  
 0b - Self-reception enabled.  
1b - Self-reception disabled. |
| 16 | Individual Rx Masking And Queue Enable |
| IRMQ | This bit indicates whether Rx matching process will be based either on individual masking and queue or on masking scheme with RXMGMSK, RX14MASK, RX15MASK, and RXFGMASK. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.  
 0b - Individual Rx masking and queue feature are disabled. For backward compatibility with legacy applications, the reading of C/S word locks the MB even if it is EMPTY.  
1b - Individual Rx masking and queue feature are enabled. |
| 15 | DMA Enable |
| DMA | DMA controls whether the DMA feature is enabled or not. The DMA feature can only be used in Rx FIFO, so consequently MCR[RFEN] must be asserted. When DMA and RFEN are set, IFLAG1[BUF5l] generates the DMA request and no RX FIFO interrupt is generated. This bit can be written in Freeze mode only as it is blocked by hardware in other modes.  
 0b - DMA feature for RX FIFO disabled.  
1b - DMA feature for RX FIFO enabled. |
| 14 | Reserved |
| 13 | Local Priority Enable |
| LPRIEN | This bit is provided for backwards compatibility with legacy applications. It controls whether the local priority feature is enabled or not. It is used to expand the ID used during the arbitration process. With this expanded ID concept, the arbitration process is done based on the full 32-bit word, but the actual transmitted ID still has 11-bit for standard frames and 29-bit for extended frames. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  
 0b - Local Priority disabled.  
1b - Local Priority enabled. |
| 12 | Abort Enable |
| AEN | When asserted, this bit enables the Tx abort mechanism. This mechanism guarantees a safe procedure for aborting a pending transmission, so that no frame is sent in the CAN bus without notification. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.  
NOTE: When MCR[AEN] is asserted, only the abort mechanism (see Transmission abort mechanism) must be used for updating mailboxes configured for transmission.  
CAUTION: Writing the Abort code into Rx mailboxes can cause unpredictable results when MCR[AEN] is asserted.  
 0b - Abort disabled.  
1b - Abort enabled. |
| 11 | CAN FD operation enable |
| FDEN | This bit enables the CAN with Flexible Data rate (CAN FD) operation. This bit can be written in Freeze mode only.  
NOTE: FlexCAN is able to transmit FD frame format according to ISO 11898-1.  
NOTE: The Rx FIFO Enable (RFEN) bit cannot be set if FDEN is asserted.  
 0b - CAN FD is disabled. FlexCAN is able to receive and transmit messages in CAN 2.0 format.  
1b - CAN FD is enabled. FlexCAN is able to receive and transmit messages in both CAN FD and CAN 2.0 formats. |
### Field 10

**Function:** Reserved

### Field 9-8 (IDAM)

**ID Acceptance Mode**

This 2-bit field identifies the format of the Rx FIFO ID filter table elements. Note that all elements of the table are configured at the same time by this field (they are all the same format). See Rx FIFO structure. This field can be written only in Freeze mode because it is blocked by hardware in other modes.

- **00b - Format A:** One full ID (standard and extended) per ID filter table element.
- **01b - Format B:** Two full standard IDs or two partial 14-bit (standard and extended) IDs per ID filter table element.
- **10b - Format C:** Four partial 8-bit standard IDs per ID filter table element.
- **11b - Format D:** All frames rejected.

### Field 7-6 (MAXMB)

**Number Of The Last Message Buffer**

This 7-bit field defines the number of the last message buffers that will take part in the matching and arbitration processes. The reset value (0x0F) is equivalent to a 16 MB configuration. This field can be written only in Freeze mode because it is blocked by hardware in other modes.

Number of the last MB = MAXMB

**NOTE:** MAXMB must be programmed with a value smaller than or equal to the number of available message buffers, as described in FlexCAN memory partition for CAN FD.

Additionally, the definition of MAXMB value must take into account the region of MBs occupied by Rx FIFO and its ID filters table space defined by CTRL2[RFFN]. MAXMB also impacts the definition of the minimum number of peripheral clocks per CAN bit as described in Table 45-14.

### 45.6.2.3 Control 1 register (CTRL1)

#### 45.6.2.3.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>CTRL1</td>
<td>4h</td>
</tr>
</tbody>
</table>

#### 45.6.2.3.2 Function

This register is defined for specific FlexCAN control features related to the CAN bus, such as bit rate, programmable sampling point within an Rx bit, Loop Back mode, Listen-Only mode, Bus Off recovery behavior, and interrupt enabling (Bus-Off, Error, Warning). It also determines the division factor for the clock prescaler.
The CAN bit timing variables (PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW) can also be configured in the CBT register, which extends the range of all these variables. If CBT[BTF] is set, PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields of CTRL1 become read only.

**NOTE**

When the CAN FD feature is enabled, do not use the PRESDIV, RJW, PSEG1, PSEG2, and PROPSEG fields of the CTRL1 register for CAN bit timing. Instead use the CBT register's EPRESDIV, ERJW, EPSEG1, EPSEG2, and EPROPSEG fields.

The contents of this register are not affected by soft reset.

**NOTE**

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>RJW</td>
<td>This 2-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization. One time quantum is equal to the Sclock period. The valid programmable values are 0–3. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Resync Jump Width = RJW + 1.</td>
</tr>
<tr>
<td>PSEG1</td>
<td>Phase Segment 1 This 3-bit field defines the length of phase segment 1 in the bit time. The valid programmable values are 0–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 1 = (PSEG1 + 1) × Time-Quanta.</td>
</tr>
<tr>
<td>PSEG2</td>
<td>Phase Segment 2 This 3-bit field defines the length of phase segment 2 in the bit time. The valid programmable values are 1–7. This field can be written only in Freeze mode because it is blocked by hardware in other modes. Phase Buffer Segment 2 = (PSEG2 + 1) × Time-Quanta.</td>
</tr>
<tr>
<td>BOFFMSK</td>
<td>Bus Off Interrupt Mask This bit provides a mask for the Bus Off interrupt ESR1[BOFFINT]. 0b - Bus Off interrupt disabled. 1b - Bus Off interrupt enabled.</td>
</tr>
<tr>
<td>ERRMSK</td>
<td>Error Interrupt Mask This bit provides a mask for the Error interrupt ESR1[ERRINT]. 0b - Error interrupt disabled. 1b - Error interrupt enabled.</td>
</tr>
<tr>
<td>CLKSRC</td>
<td>CAN Engine Clock Source This bit selects the clock source to the CAN Protocol Engine (PE) to be either the peripheral clock or the oscillator clock. The selected clock is the one fed to the prescaler to generate the serial clock (Sclock). In order to guarantee reliable operation, this bit can be written only in Disable mode because it is blocked by hardware in other modes. See Protocol timing.</td>
</tr>
<tr>
<td>LPB</td>
<td>Loop Back Mode This bit configures FlexCAN to operate in Loop-Back mode. In this mode, FlexCAN performs an internal loop back that can be used for self-test operation. The bit stream output of the transmitter is fed back internally to the receiver input. The Rx CAN input pin is ignored and the Tx CAN output goes to the recessive state (logic 1). FlexCAN behaves as it normally does when transmitting, and treats its own transmitted message as a message received from a remote node. In this mode, FlexCAN ignores the bit sent during the ACK slot in the CAN frame acknowledge field, generating an internal acknowledge bit to ensure proper reception of its own message. Both transmit and receive interrupts are generated. This bit can be written only in Freeze mode because it is blocked by hardware in other modes.</td>
</tr>
<tr>
<td>TWRNMSK</td>
<td>Tx Warning Interrupt Mask</td>
</tr>
</tbody>
</table>

Table continues on the next page...
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
|       | This bit provides a mask for the Tx Warning interrupt associated with the TWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] is negated. This bit can be written only if MCR[WRNEN] is asserted.  
0b - Tx Warning interrupt disabled.  
1b - Tx Warning interrupt enabled. |
| 10    | Rx Warning Interrupt Mask  
This bit provides a mask for the Rx Warning interrupt associated with the RWRNINT flag in the Error and Status Register 1 (ESR1). This bit is read as zero when MCR[WRNEN] bit is negated. This bit can be written only if MCR[WRNEN] bit is asserted.  
0b - Rx Warning interrupt disabled.  
1b - Rx Warning interrupt enabled. |
| 9     | Reserved |
| 8     | Reserved |
| 7     | CAN Bit Sampling  
This bit defines the sampling mode of CAN bits at the Rx input. It can be written in Freeze mode only, because it is blocked by hardware in other modes.  
NOTE: For proper operation, to assert SMP it is necessary to guarantee a minimum value of two TQs in CTRL1[PSEG1] (or CBT[EPSEG1]). This bit cannot be asserted when CAN FD is enabled (MCR[FDEN] = 1).  
0b - Just one sample is used to determine the bit value.  
1b - Three samples are used to determine the value of the received bit: the regular one (sample point) and two preceding samples; a majority rule is used. |
| 6     | Bus Off Recovery  
This bit defines how FlexCAN recovers from Bus Off state. If this bit is negated, automatic recovering from Bus Off state occurs according to the CAN Specification 2.0B. If the bit is asserted, automatic recovering from Bus Off is disabled and the module remains in Bus Off state until the bit is negated by the user. If the negation occurs before 128 sequences of 11 recessive bits are detected on the CAN bus, then Bus Off recovery happens as if the BOFFREC bit had never been asserted. If the negation occurs after 128 sequences of 11 recessive bits occurred, then FlexCAN will resynchronize to the bus by waiting for 11 recessive bits before joining the bus. After negation, the BOFFREC bit can be reasserted again during Bus Off, but it will be effective only the next time the module enters Bus Off. If BOFFREC was negated when the module entered Bus Off, asserting it during Bus Off will not be effective for the current Bus Off recovery.  
NOTE: See Bus off in the CAN Protocol standard (ISO 11898-1) for details.  
0b - Automatic recovering from Bus Off state enabled.  
1b - Automatic recovering from Bus Off state disabled. |
| 5     | Timer Sync  
This bit enables a mechanism that resets the free running timer each time a message is received in message buffer 0. This feature provides means to synchronize multiple FlexCAN stations with a special “SYNC” message, that is, global network time. If MCR[RFEN] is set (Rx FIFO enabled), the first available mailbox, according to CTRL2[RFFN] setting, is used for timer synchronization instead of MB0. This bit can be written in Freeze mode only because it is blocked by hardware in other modes.  
0b - Timer sync feature disabled  
1b - Timer sync feature enabled |
| 4     | Lowest Buffer Transmitted First |

#### 45.6.2.4 Free Running Timer (TIMER)

#### 45.6.2.4.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>TIMER</td>
<td>8h</td>
</tr>
</tbody>
</table>

#### 45.6.2.4.2 Function

This register represents a 16-bit free-running counter that can be read and written by the CPU. The timer starts from 0x0 after Reset, counts linearly to 0xFFFF, and wraps around.

When CTRL2[TIMER_SRC] is asserted, the timer is continuously incremented by an external time tick. The time tick must be synchronous to the peripheral clock, with a minimum pulse width of one clock cycle.
When CTRL2[TIMER_SRC] is negated, the timer is incremented by the CAN bit clock, which defines the baud rate on the CAN bus. During a message transmission/reception, it increments by one for each bit that is received or transmitted. When there is no message on the bus, it counts using the previously programmed baud rate. The timer is not incremented during Disable, Doze, Stop and Freeze modes.

The timer value is captured when the second bit of the identifier field of any frame is on the CAN bus. This captured value is written into the time stamp entry in a message buffer after a successful reception or transmission of a message.

If CTRL1[TSYN] is asserted, the timer is reset whenever a message is received in the first available mailbox, according to CTRL2[RFFN] setting.

The CPU can write to this register anytime. However, if the write occurs at the same time that the timer is being reset by a reception in the first mailbox, then the write value is discarded.

Reading this register affects the mailbox unlocking procedure (see Mailbox lock mechanism).

45.6.2.5  Rx Mailboxes Global Mask register (RXMGMASK)

45.6.2.5.1  Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RXMGMASK</td>
<td>10h</td>
</tr>
</tbody>
</table>

45.6.2.5.2  Function

This register is located in RAM.

RXMGMASK is provided for legacy application support.

- When MCR[IRMQ] is negated, RXMGMASK is always in effect (the bits in the MG field will mask the mailbox filter bits).
- When MCR[IRMQ] is asserted, RXMGMASK has no effect (the bits in the MG field will not mask the mailbox filter bits).

RXMGMASK is used to mask the filter fields of all Rx MBs, excluding MBs 14-15, which have individual mask registers.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

45.6.2.5.3  Diagram

<td>1</td>
<td>1</td>
<td>MG[31]</td>
</tr>
</tbody>
</table>

1. RTR bit of the incoming frame. It is saved into an auxiliary MB called Rx serial message buffer (Rx SMB).
2. If CTRL2[EACEN] is negated, the RTR bit of mailbox is never compared with the RTR bit of the incoming frame.
3. If CTRL2[EACEN] is negated, the IDE bit of mailbox is always compared with the IDE bit of the incoming frame.

0b - The corresponding bit in the filter is "don't care."
1b - The corresponding bit in the filter is checked.

### 45.6.2.6 Rx 14 Mask register (RX14MASK)

#### 45.6.2.6.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RX14MASK</td>
<td>14h</td>
</tr>
</tbody>
</table>

#### 45.6.2.6.2 Function

This register is located in RAM.

RX14MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX14MASK has no effect.

RX14MASK is used to mask the filter fields of message buffer 14.
This register can only be programmed when the module is in Freeze mode as it is blocked by hardware in other modes.

45.6.2.7.2  Function

This register is located in RAM.

RX15MASK is provided for legacy application support. When MCR[IRMQ] is asserted, RX15MASK has no effect.
RX15MASK is used to mask the filter fields of message buffer 15.

This register can be programmed only when the module is in Freeze mode because it is blocked by hardware in other modes.

### 45.6.2.8.2 Function

This register has four 8-bit fields reflecting the value of the FlexCAN error counters:

- Transmit Error Counter (TXERRCNT field)
• Receive Error Counter (RXERRCNT field)
• Transmit Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (TXERRCNT_FAST field)
• Receive Error Counter for errors detected in the data phase of CAN FD messages with the BRS bit set (RXERRCNT_FAST field)

The TXERRCNT and RXERRCNT counters take into account all errors in both CAN FD and non-FD message formats. TXERRCNT_FAST and RXERRCNT_FAST are dedicated to count only the errors that occur in the data phase of CAN FD frames with the BRS bit set.

The Fault Confinement state (ESR1[FLTCONF]) is updated based on TXERRCNT and RXERRCNT counters only. TXERRCNT and RXERRCNT counters can be written in Freeze mode only. TXERRCNT_FAST and RXERRCNT_FAST counters are read-only except in Freeze mode when the CPU can write value zero. The rules for increasing and decreasing these counters are described in the CAN protocol and are completely implemented in the FlexCAN module.

The following are the basic rules for FlexCAN bus state transitions:

• If the value of TXERRCNT or RXERRCNT becomes greater than or equal to 128, ESR1[FLTCONF] is updated to reflect Error Passive state.
• If the FlexCAN state is Error Passive, and either TXERRCNT or RXERRCNT decrements to a value less than or equal to 127 when the other already satisfies this condition, ESR1[FLTCONF] is updated to reflect Error Active state.
• If the value of TXERRCNT becomes greater than 255, ESR1[FLTCONF] is updated to reflect Bus Off state, and an interrupt may be issued. The value of TXERRCNT is then reset to zero.
• If FlexCAN is in Bus Off state, then TXERRCNT is cascaded together with another internal counter to count the 128th occurrences of 11 consecutive recessive bits on the bus. Hence, TXERRCNT is reset to zero and counts in a manner where the internal counter counts 11 such bits and then wraps around when incrementing the TXERRCNT. When TXERRCNT reaches the value of 128, ESR1[FLTCONF] is updated to be Error Active and both error counters are reset to zero. At any instance of dominant bit following a stream of less than 11 consecutive recessive bits, the internal counter resets itself to zero without affecting the TXERRCNT value. The TXERRCNT_FAST counter is frozen during Bus Off.
• If during system startup only one node is operating, then its TXERRCNT increases in each message it is trying to transmit, as a result of acknowledge errors (indicated by the ACKERR bit in the Error and Status Register). After the transition to Error Passive state, TXERRCNT does not increment anymore by acknowledge errors. Therefore the device never goes to the Bus Off state.
- If RXERRCNT increases to a value greater than 127, it is not incremented further, even if more errors are detected when being a receiver. At the next successful message reception, the counter is set to a value between 119 and 127 to return to Error Active state.

- TXERRCNT_FAST and RXERRCNT_FAST error counter values increment and decrement based on errors detected only in the data phase of CAN FD frames with the BRS bit set, following the same increment and decrement rules as TXERRCNT and RXERRCNT counters. These counters do not wrap around and get stuck at their maximum value (255). They stop counting and keep their values frozen when FlexCAN is in Bus Off state. They are reset when FlexCAN leaves Bus Off state and restart counting after FlexCAN returns to Error Active state.

**NOTE**

See Fault confinement in the CAN Protocol standard (ISO 11898-1) for details.

### 45.6.2.9 Error and Status 1 register (ESR1)

#### 45.6.2.9.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>ESR1</td>
<td>20h</td>
</tr>
</tbody>
</table>

#### 45.6.2.9.2 Function

This register reports various error conditions detected in the reception and transmission of a CAN frame, some general status of the device, and is the source of some interrupts to the CPU. The reported error conditions are:

- Errors detected in CAN frames of any format:
  - BIT1ERR
  - BIT0ERR
  - ACKKERR
  - CRCERR
  - FRMERR
  - STFERR
- Errors detected in the data phase of CAN FD frames with the BRS bit set only:
  - BIT1ERR_FAST
  - BIT0ERR_FAST
  - CRCERR_FAST
  - FRMERR_FAST
  - STFERR_FAST

An error detected in a single CAN frame may be reported by one or more error flags. Also, error reporting is cumulative, in case more error events happen in the next frames when the CPU does not attempt to read this register.

Status bits:
- TXWRN
- RXWRN
It is recommended that the CPU use the following procedure when servicing interrupt requests generated by these bits:

1. Read this register to capture all error condition and status bits. This action clears the respective bits that were set since the last read access.
2. Write 1 to clear the interrupt bit that has triggered the interrupt request.
3. Write 1 to clear the ERR_OVR bit, if it is set.

Starting from all error flags cleared, a first error event sets either the ERRINT or the ERRINT_FAST (provided the corresponding mask bit is asserted). If other error events in subsequent frames happen before the CPU serves the interrupt request, the ERR_OVR bit is set to indicate that errors from different frames have accumulated.

| 15 BIT1ERR | Bit1 Error  
This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message.  
**NOTE:** This bit is not set by a transmitter in case of arbitration field or ACK slot, or in case of a node sending a passive error flag that detects dominant bits.  
0b - No such occurrence.  
1b - At least one bit sent as recessive is received as dominant. |
| 14 BIT0ERR | Bit0 Error  
This bit indicates when an inconsistency occurs between the transmitted and the received bit in a non-CAN FD message or in the arbitration or data phase of a CAN FD message.  
0b - No such occurrence.  
1b - At least one bit sent as dominant is received as recessive. |
| 13 ACKERR | Acknowledge Error  
This bit indicates that an Acknowledge Error has been detected by the transmitter node, that is, a dominant bit has not been detected during the ACK SLOT.  
0b - No such occurrence.  
1b - An ACK error occurred since last read of this register. |
| 12 CRCERR | Cyclic Redundancy Check Error  
This bit indicates that a CRC error has been detected by the receiver node either in a non-FD message or in the arbitration or data phase of a frame in CAN FD format, that is, the calculated CRC is different from the received.  
0b - No such occurrence.  
1b - A CRC error occurred since last read of this register. |
| 11 FRMERR | Form Error  
This bit indicates that a form error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node, that is, a fixed-form bit field contains at least one illegal bit.  
0b - No such occurrence.  
1b - A Form Error occurred since last read of this register. |
| 10 STFERR | Stuffing Error  
This bit indicates that a stuffing error has been detected in a non-FD message or else in an FD message's arbitration or data phase by the receiver node.  
0b - No such occurrence.  
1b - A stuffing error occurred since last read of this register. |
| 9 TXWRN | TX Error Warning  
This bit indicates when repetitive errors are occurring during message transmission and is affected by the value of TXERRCNT in ECR register only. This bit is not updated during Freeze mode.  
0b - No such occurrence.  
1b - TXERRCNT is greater than or equal to 96. |
| 8 RXWRN | Rx Error Warning  
This bit indicates when repetitive errors are occurring during message reception and is affected by the value of RXERRCNT in ECR register only. This bit is not updated during Freeze mode.  
0b - No such occurrence.  
1b - RXERRCNT is greater than or equal to 96. |
| 7 IDLE | |

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| **IDLE** | This bit indicates when CAN bus is in IDLE state. See the table in the overall ESR1 register description.  
|        | 0b - No such occurrence.  
|        | 1b - CAN bus is now IDLE. |
| **6 TX** | FlexCAN In Transmission  
|         | This bit indicates if FlexCAN is transmitting a message. See the table in the overall ESR1 register description.  
|         | 0b - FlexCAN is not transmitting a message.  
|         | 1b - FlexCAN is transmitting a message. |
| **5-4 FLTCONF** | Fault Confinement State  
|               | This 2-bit field indicates the confinement state of the FlexCAN module.  
|               | If CTRL1[LOM] is asserted, after a delay that depends on the CAN bit timing, ESR1[FLTCONF] will indicate Error Passive. The very same delay affects the way that ESR1[FLTCONF] reflects an update to ECR register by the CPU. It may be necessary to wait up to one CAN bit time to get them coherent again.  
|               | This bit field is affected by soft reset, but if the LOM bit is asserted, its reset value lasts just one CAN bit. After this time, ESR1[FLTCONF] reports Error Passive.  
|               | 00b - Error Active  
|               | 01b - Error Passive  
|               | 1xb - Bus Off |
| **3 RX** | FlexCAN In Reception  
|          | This bit indicates if FlexCAN is receiving a message. See the table in the overall ESR1 register description.  
|          | 0b - FlexCAN is not receiving a message.  
|          | 1b - FlexCAN is receiving a message. |
| **2 BOFFINT** | Bus Off Interrupt  
|             | This bit is set when FlexCAN enters Bus Off state. If the corresponding mask bit in the Control Register 1 (CTRL1[BOFFMSK]) is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.  
|             | 0b - No such occurrence.  
|             | 1b - FlexCAN module entered Bus Off state. |
| **1 ERRINT** | Error Interrupt  
|             | This bit indicates that at least one of the error bits (BIT1ERR, BIT0ERR, ACKERR, CRCERR, FRMERR, or STFERR) is set. If the corresponding mask bit CTRL1[ERRMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1. Writing 0 has no effect.  
|             | 0b - No such occurrence.  
|             | 1b - Indicates setting of any error bit in the Error and Status register. |
| **0 WAKINT** | Wake-Up Interrupt  
|             | This field applies when FlexCAN is in low-power mode under Self Wake Up mechanism:  
|             | • Doze mode  
|             | • Stop mode  
|             | When a recessive-to-dominant transition is detected on the CAN bus and if MCR[WAKMSK] is set, an interrupt is generated to the CPU. This bit is cleared by writing it to 1.  
|             | When MCR[SLFWAK] is negated, this flag is masked. The CPU must clear this flag before disabling the bit. Otherwise it will be set when SLFWAK is set again. Writing 0 has no effect.  
|             | 0b - No such occurrence.  
|             | 1b - Indicates a recessive to dominant transition was received on the CAN bus. |

- 1b - The corresponding buffer interrupt is enabled.
45.6.2.12  Interrupt Flags 2 register (IFLAG2)

45.6.2.12.1  Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFLAG2</td>
<td>2Ch</td>
</tr>
</tbody>
</table>

45.6.2.12.2  Function

This register defines the flags for the 32 message buffer interrupts for MB63 to MB32. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the respective IFLAG2 bit. If the corresponding IMASK2 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect.

Before updating MCR[MAXMB], CPU must service the IFLAG2 bits whose MB value is greater than the MAXMB to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>IFLAG1</td>
<td>30h</td>
</tr>
</tbody>
</table>

#### 45.6.2.13.2 Function

This register defines the flags for the 32 message buffer interrupts for MB31 to MB0. It contains one interrupt flag bit per buffer. Each successful transmission or reception sets the corresponding IFLAG1 bit. If the corresponding IMASK1 bit is set, an interrupt will be generated. The interrupt flag must be cleared by writing 1 to it. Writing 0 has no effect. There is an exception when DMA for Rx FIFO is enabled, as described below.

The BUF7I to BUF5I flags are also used to represent FIFO interrupts when the Rx FIFO is enabled. When MCR[RFEN] is set and MCR[DMA] is negated, the function of the eight least significant interrupt flags changes: BUF7I, BUF6I, and BUF5I indicate operating conditions of the FIFO, BUF0I is used to empty FIFO, and BUF4I to BUF1I bits are reserved.

Before enabling MCR[RFEN], the CPU must service the IFLAG bits asserted in the Rx FIFO region; see Rx FIFO. Otherwise, these IFLAG bits will mistakenly show the related MBs now belonging to FIFO as having contents to be serviced. When MCR[RFEN] is negated, the FIFO flags must be cleared. The same care must be taken when a CTRL2[RFFN] value is selected, extending Rx FIFO filters beyond MB7. For example, when RFFN is 0x8, the MB0–23 range is occupied by Rx FIFO filters and related IFLAG bits must be cleared.

When both the MCR[RFEN] and MCR[DMA] bits are asserted (DMA feature for Rx FIFO enabled), the function of the eight least significant interrupt flags (BUF7I–BUF0I) are changed to support the DMA operation. BUF7I and BUF6I are not used, as well as BUF4I–BUF1I. BUF5I indicates operating condition of FIFO, and BUF0I is used to empty FIFO. Moreover, BUF5I does not generate a CPU interrupt, but generates a DMA request. IMASK1 bits in Rx FIFO region are not considered when bit MCR[DMA] is enabled. In addition the CPU must not clear the flag BUF5I when DMA is enabled. Before enabling MCR[DMA], the CPU must service the IFLAGs asserted in the Rx FIFO region. When MCR[DMA] is negated, the FIFO must be empty. FIFO must be disabled when MCR[FDEN] is enabled.
Before updating MCR[MAXMB], CPU must service the IFLAG1 bits whose MB value is greater than the MCR[MAXMB] to be updated; otherwise, they will remain set and be inconsistent with the number of MBs available.

</tr>
<tr>
<td>BUF6I</td>
<td>When MCR[RFEN] is cleared (Rx FIFO disabled), this bit flags the interrupt for MB6.</td>
</tr>
<tr>
<td>NOTE:</td>
<td>This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes.</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
### Field | Function
---|---
| Field | Function |
| The BUF6I flag represents Rx FIFO warning when MCR[RFEN] is set. In this case, the flag indicates when the number of unread messages within the Rx FIFO is increased to five from four due to the reception of a new one, meaning that the Rx FIFO is almost full. Note that if the flag is cleared when the number of unread messages is greater than four, it does not assert again until the number of unread messages within the Rx FIFO is decreased to be equal to or less than four. |
| 0b - No occurrence of MB6 completing transmission/reception when MCR[RFEN]=0, or of Rx FIFO almost full when MCR[RFEN]=1 |
| 1b - MB6 completed transmission/reception when MCR[RFEN]=0, or Rx FIFO almost full when MCR[RFEN]=1 |
| 5 | BUF5I | Buffer MB5 Interrupt Or Frames available in Rx FIFO |
| When MCR[RFEN] is cleared (Rx FIFO disabled), this field flags the interrupt for MB5. |
| NOTE: This flag is cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. |
| When MCR[RFEN] is set (Rx FIFO enabled), the BUF5I flag represents "Frames available in Rx FIFO" and indicates that at least one frame is available to be read from the Rx FIFO. When the MCR[DMA] bit is enabled, this flag generates a DMA request and the CPU must not clear this bit by writing 1 in BUF5I. |
| 0b - No occurrence of MB5 completing transmission/reception when MCR[RFEN]=0, or of frame(s) available in the FIFO, when MCR[RFEN]=1 |
| 1b - MB5 completed transmission/reception when MCR[RFEN]=0, or frame(s) available in the Rx FIFO when MCR[RFEN]=1. It generates a DMA request in case of MCR[RFEN] and MCR[DMA] are enabled. |
| 4-1 | BUF4TO1I | Buffer MBi Interrupt Or Reserved |
| When MCR[RFEN] is cleared (Rx FIFO disabled), these bits flag the interrupts for MB4 to MB1. |
| NOTE: These flags are cleared by the FlexCAN whenever MCR[RFEN] is changed by CPU writes. |
| The BUF4TO1I flags are reserved when MCR[RFEN] is set. |
| 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. |
| 1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0. |
| 0 | BUF0I | Buffer MB0 Interrupt Or Clear FIFO bit |
| When MCR[RFEN] is cleared (Rx FIFO disabled), this field flags the interrupt for MB0. If the Rx FIFO is enabled, this bit is used to trigger the clear FIFO operation. This operation empties FIFO contents. Before performing this operation the CPU must service all FIFO related IFLAGs. When MCR[DMA] is enabled this operation also clears the BUF5I flag and consequently aborts the DMA request. The clear FIFO operation occurs when the CPU writes 1 in BUF0I. It is only allowed in Freeze mode and is blocked by hardware in other conditions. |
| 0b - The corresponding buffer has no occurrence of successfully completed transmission or reception when MCR[RFEN]=0. |
| 1b - The corresponding buffer has successfully completed transmission or reception when MCR[RFEN]=0. |

### 45.6.2.14 Control 2 register (CTRL2)
45.6.2.14.1 Offset

45.6.2.14.2 Function

This register complements Control1 register, providing control bits for memory write access in Freeze mode, for extending FIFO filter quantity, and to adjust the operation of internal FlexCAN processes like matching and arbitration.

The contents of this register are not affected by soft reset.

This table shows how the Rx FIFO filter structure is determined by the value of CTRL2[RFFN]. See the CTRL2[RFFN] field description for more information.

<td>28</td>
<td>Reserved</td>
</tr>
<tr>
<td>27-24</td>
<td>RFFN</td>
</tr>
<tr>
<td>RFFN</td>
<td>Number Of Rx FIFO Filters</td>
</tr>
<tr>
<td>This 4-bit field defines the number of Rx FIFO filters, as shown in Table 45-20. The maximum selectable number of filters is determined by the chip. This field can only be written in Freeze mode as it is blocked by hardware in other modes. This field must not be programmed with values that cause the number of message buffers occupied by Rx FIFO and ID Filter to exceed the number of mailboxes present, as defined by MCR[MAXMB].</td>
<td></td>
</tr>
<tr>
<td>NOTE: Each group of eight filters occupies a memory space equivalent to two message buffers, which means that the more filters are implemented the fewer mailboxes will be available.</td>
<td></td>
</tr>
<tr>
<td>Considering that the Rx FIFO occupies the memory space originally reserved for MB0-5, RFFN should be programmed with a value corresponding to a number of filters not greater than the number of available memory words, which can be calculated as follows:</td>
<td></td>
</tr>
<tr>
<td>(SETUP_MB - 6) × 4</td>
<td></td>
</tr>
</tbody>
</table>

Table continues on the next page...
where SETUP_MB is the smaller of the parameter NUMBER_OF_MB and MCR[\text{MAXMB}].

The number of remaining mailboxes available will be:

\[(\text{SETUP_MB} - 8) - (\text{RFFN} \times 2)\]

If the number of Rx FIFO filters programmed through RFFN exceeds the SETUP_MB value (memory space available), then the exceeding ones will not be functional.

**NOTE:**
- The number of the last remaining available mailboxes is defined by the smaller of \(\text{NUMBER_OF_MB} - 1\) and \(\text{MCR[MAXMB]}\).
- If Rx Individual Mask registers are not enabled then all Rx FIFO filters are affected by the Rx FIFO Global Mask.

### Field | Function
--- | ---

| 23-19 | Tx Arbitration Start Delay |
|       | This 5-bit field indicates how many CAN bits the Tx arbitration process start point can be delayed from the first bit of CRC field on CAN bus. See Tx arbitration start delay for more details. This field can be written only in Freeze mode because it is blocked by hardware in other modes. |

| 18 | Mailboxes Reception Priority |
|     | If this bit is set the matching process starts from the mailboxes and if no match occurs the matching continues on the Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. |
|     | 0b - Matching starts from Rx FIFO or Enhanced Rx FIFO and continues on mailboxes. |
|     | 1b - Matching starts from mailboxes and continues on Rx FIFO. |

| 17 | Remote Request Storing |
|     | If this bit is asserted a remote request frame is submitted to a matching process and stored in the corresponding message buffer in the same fashion as a data frame. No automatic remote response frame will be generated. |
|     | If this bit is negated the remote request frame is submitted to a matching process and an automatic remote response frame is generated if a message buffer with CODE=0b1010 is found with the same ID. |
|     | This bit can be written only in Freeze mode because it is blocked by hardware in other modes. |
|     | 0b - Remote response frame is generated. |
|     | 1b - Remote request frame is stored. |

| 16 | Entire Frame Arbitration Field Comparison Enable For Rx Mailboxes |
|     | This bit controls the comparison of IDE and RTR bits within Rx mailbox filters with their corresponding bits in the incoming frame by the matching process. This bit does not affect matching for Rx FIFO. This bit can be written only in Freeze mode because it is blocked by hardware in other modes. |
|     | 0b - Rx mailbox filter’s IDE bit is always compared and RTR is never compared despite mask bits. |
|     | 1b - Enables the comparison of both Rx mailbox filter’s IDE and RTR bit with their corresponding bits within the incoming frame. Mask bits do apply. |

| 15 | Timer Source |
|     | Selects the time tick source used for incrementing the free running timer counter. This bit can be written in Freeze mode only. |
|     | 0b - The free running timer is clocked by the CAN bit clock, which defines the baud rate on the CAN bus. |
|     | 1b - The free running timer is clocked by an external time tick. The period can be either adjusted to be equal to the baud rate on the CAN bus, or a different value as required. See the device-specific section for details about the external time tick. |

| 14 | Protocol Exception Enable |
|     | This bit enables the protocol exception feature. |
|     | This field is writable only in Freeze mode. |

**NOTE:** See Protocol exception event in the CAN Protocol standard (ISO 11898-1) for details.

</tbody>
</table>

45.6.2.16.2 Function

This register provides information about the CRC of transmitted messages for non-FD messages. This register only reports the 15 low order bits of CRC calculations for messages in CAN FD format that require either 17 or 21 bits. For CAN FD format frames, the FDCRC register must be used. This register is updated at the same time the Tx interrupt flag is asserted.

NOTE
See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RXFGMASK</td>
<td>48h</td>
</tr>
</tbody>
</table>

45.6.2.17.2 Function

This register is located in RAM.

If Rx FIFO is enabled, RXFGMASK is used to mask the Rx FIFO ID filter table elements that do not have a corresponding RXIMR according to CTRL2[RFFN] field setting.

This register can only be written in Freeze mode as it is blocked by hardware in other modes.

The following table shows how the FGM bits correspond to each IDAF field.
Table 45-21. Correspondence of Rx FIFO global mask bits to IDF fields

<table>
<thead>
<tr>
<th>Rx FIFO ID filter table elements format (MCR[IDAM])</th>
<th>Identifier acceptance filter fields</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>RTR</td>
</tr>
<tr>
<td>C</td>
<td>—</td>
</tr>
</tbody>
</table>

1. If MCR[IDAM] is equivalent to format B, only the fourteen most significant bits of the identifier of the incoming frame are compared with the Rx FIFO filter.
2. If MCR[IDAM] is equivalent to format C, only the eight most significant bits of the identifier of the incoming frame are compared with the Rx FIFO filter.

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RXFIR</td>
<td>4Ch</td>
</tr>
</tbody>
</table>

45.6.2.18.2 Function

RXFIR provides information on Rx FIFO.

This register is the port through which the CPU accesses the output of the RXFIR FIFO located in RAM. The RXFIR FIFO is written by the FlexCAN whenever a new message is moved into the Rx FIFO. Also, its output is updated whenever the output of the Rx FIFO is updated with the next message. See Rx FIFO for instructions on reading this register.

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>CBT</td>
<td>50h</td>
</tr>
</tbody>
</table>

45.6.2.19.2 Function

This register is an alternative way to store the CAN bit timing variables described in CTRL1 register. EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW are extended versions of PRESDIV, PROPSEG, PSEG1, PSEG2, and RJW fields respectively.

The BTF bit selects the use of the timing variables defined in this register.

The contents of this register are not affected by soft reset.

**NOTE**

The CAN bit variables in CTRL1 and in CBT are stored in the same register.

**NOTE**

When the CAN FD feature is enabled (MCR[FDEN] is set), always set CBT[BTF].

**NOTE**

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

### 45.6.2.19.4 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 31 BTF | Bit Timing Format Enable  
Enables the use of extended CAN bit timing fields EPRESDIV, EPROPSEG, EPSEG1, EPSEG2, and ERJW replacing the CAN bit timing variables defined in CTRL1 register. This field can be written in Freeze mode only.  
0b - Extended bit time definitions disabled.  
1b - Extended bit time definitions enabled. |
| 30-21 EPRESDIV | Extended Prescaler Division Factor  
This 10-bit field defines the ratio between the PE clock frequency and the serial clock (Sclock) frequency when CBT[BTF] is asserted, otherwise it has no effect. It extends the CTRL1[PRESDIV] value range.  
The Sclock period defines the time quantum of the CAN protocol. For the reset value, the Sclock frequency is equal to the PE clock frequency (see Protocol timing). This field can be written only in Freeze mode because it is blocked by hardware in other modes.  
Sclock frequency = PE clock frequency / (EPRESDIV + 1) |
| 20-16 ERJW | Extended Resync Jump Width  
This 5-bit field defines the maximum number of time quanta that a bit time can be changed by one resynchronization when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[RJW] value range.  
One time quantum is equal to the Sclock period. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  
Resync Jump Width = ERJW + 1. |
| 15-10 EPROPSEG | Extended Propagation Segment  
This 6-bit field defines the length of the propagation segment in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PROPSEG] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  
Propagation Segment Time = (EPROPSEG + 1) × Time-Quanta.  
Time-Quantum = one Sclock period. |
| 9-5 EPSEG1 | Extended Phase Segment 1  
This 5-bit field defines the length of phase segment 1 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG1] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  
Phase Buffer Segment 1 = (EPSEG1 + 1) × Time-Quanta.  
Time-Quantum = one Sclock period. |
| 4-0 EPSEG2 | Extended Phase Segment 2  
This 5-bit field defines the length of phase segment 2 in the bit time when CBT[BTF] bit is asserted, otherwise it has no effect. It extends the CTRL1[PSEG2] value range. This field can be written only in Freeze mode because it is blocked by hardware in other modes.  
Phase Buffer Segment 1 = (EPSEG2 + 1) × Time-Quanta.  
Time-Quantum = one Sclock period. |
45.6.2.20  Rx Individual Mask registers (RXIMR0 - RXIMR63)

45.6.2.20.1  Offset

For \( n = 0 \) to \( 63 \):

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>RXIMRn</td>
<td>( 880h + (n \times 4h) )</td>
</tr>
</tbody>
</table>

45.6.2.20.2  Function

The RX Individual Mask Registers are used to store the acceptance masks for ID filtering in Rx MBs and the Rx FIFO.

When the Rx FIFO is disabled (MCR[RFEN] bit is negated), an individual mask is provided for each available Rx mailbox on a one-to-one correspondence. When the Rx FIFO is enabled (MCR[RFEN] bit is asserted), an individual mask is provided for each Rx FIFO ID filter table element on a one-to-one correspondence depending on the setting of CTRL2[RFFN] (see Rx FIFO).

RXIMR0 stores the individual mask associated with either MB0 or ID filter table element 0, RXIMR1 stores the individual mask associated with either MB1 or ID filter table element 1, and so on.

RXIMR registers can only be accessed by the CPU when the module is in Freeze mode; otherwise, they are blocked by hardware. These registers are not affected by reset. They are located in RAM and must be explicitly initialized prior to any reception.

It is possible for the RXIMR memory region to be accessed as general purpose memory. See Bus interface for more information.

45.6.2.21.2 Function

This register contains control bits for the CAN FD operation. It also defines the data size of message buffers allocated in different partitions of RAM (memory blocks) as described in the table below.

When an 8-byte payload is selected:
- Block R0 allocates MB0 to MB31.
- Block R1 allocates MB32 to MB63.

When a payload larger than 8 bytes is selected, the maximum number of MBs in a block is limited as described below:

<table>
<thead>
<tr>
<th>Payload size</th>
<th>Maximum number of message buffers per RAM block</th>
</tr>
</thead>
<tbody>
<tr>
<td>8 bytes</td>
<td>32</td>
</tr>
<tr>
<td>16 bytes</td>
<td>21</td>
</tr>
<tr>
<td>32 bytes</td>
<td>12</td>
</tr>
<tr>
<td>64 bytes</td>
<td>7</td>
</tr>
</tbody>
</table>
NOTE

One memory block fits exactly 32 MBs with an 8-byte payload. For other possible payload sizes, empty memory may exist between the last MB in a block and the beginning of the next block. This empty memory corresponds to less than one MB, and must not be used.

The contents of this register are not affected by soft reset.

</tbody>
</table>

*Table continues on the next page...*
TDCOFF can be written in Freeze mode only. Its value can be defined in Protocol Engine (PE) Clock periods (CANCLK, see Protocol timing for more details), and must be selected to be smaller than the CAN bit duration in the data bit rate for proper operation.

**NOTE:** It is not recommended to have TDCOFF equal to zero.

### 45.6.2.22 CAN FD Bit Timing register (FDCBT)

#### 45.6.2.22.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>FDCBT</td>
<td>C04h</td>
</tr>
</tbody>
</table>

#### 45.6.2.22.2 Function

This register stores the CAN bit timing variables used in the data phase of CAN FD messages when the FDCTRL[FDRATE] is set, compatible with CAN FD specification. FPRESDIV, FPROPSEG, FPSEG1, FPSEG2, and FRJW are used to define the time quantum duration, the number of time quanta per CAN bit, and the sample point position for the data bit rate portion of a CAN FD message with the BRS bit set.

The contents of this register are not affected by soft reset.

**NOTE**

The sum of the Fast Propagation Segment (FPROPSEG) and Fast Phase Segment 1 (FPSEG1) must be at least two time quanta.

**NOTE**

The user must ensure bit time settings and protocol engine tolerance are in compliance with the CAN Protocol standard (ISO 11898-1).

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>FDCRC</td>
<td>C08h</td>
</tr>
</tbody>
</table>

### 45.6.2.23.2 Function

This register provides information about the CRC of transmitted messages.

FlexCAN uses different CRC polynomials for different frame formats, as shown below.

The CRC_15 polynomial is used for all frames in CAN format. The CRC_17 polynomial is used for frames in CAN FD format with a DATA FIELD up to sixteen bytes. The CRC_21 polynomial is used for frames in CAN FD format with a DATA FIELD longer than sixteen bytes. Each polynomial shown below results in a Hamming distance of 6.

This register is updated at the same time the Tx Interrupt flag is asserted.
CRC_15 = 0xC599: \((x^{15} + x^{14} + x^{10} + x^8 + x^7 + x^4 + x^3 + 1)\)
CRC_17 = 0x3685B: \((x^{17} + x^{16} + x^{14} + x^{13} + x^{11} + x^6 + x^4 + x^3 + x + 1)\)
CRC_21 = 0x302899: \((x^{21} + x^{20} + x^{11} + x^{7} + x^4 + x^3 + 1)\)

**NOTE**

See CRC sequence calculation in the CAN Protocol standard (ISO 11898-1) for details.

</tr>
</tbody>
</table>
45.6.3 Message buffer structure

The message buffer structure used by the FlexCAN module is represented in the following figure. Both extended (29-bit identifier) and standard (11-bit identifier) frames used in the CAN specification (Version 2.0 Part B) are represented. Each individual MB is formed by 16, 24, 40, or 72 bytes, depending on the quantity of data bytes allocated for the message payload: 8, 16, 32, or 64 data bytes, respectively.

The memory area from 0x80 to 0x47F is used by the mailboxes. When CAN FD is enabled, the exact address for each MB depends on the size of its payload. See FlexCAN memory partition for CAN FD for more detailed information.

EDL — Extended Data Length

This bit distinguishes between CAN format and CAN FD format frames. The EDL bit must not be set for message buffers configured to RANSWER with code field 0b1010 (see table below).
**BRS — Bit Rate Switch**

This bit defines whether the bit rate is switched inside a CAN FD format frame.

**ESI — Error State Indicator**

This bit indicates if the transmitting node is error active or error passive.

**CODE — Message Buffer Code**

This 4-bit field can be accessed (read or write) by the CPU and by the FlexCAN module itself, as part of the message buffer matching and arbitration process. The encoding is shown in Table 45-24 and Table 45-25. See Functional description for additional information.

</tr>
</tbody>
</table>
### Table 45-25. Message buffer code for Tx buffers

<table>
<thead>
<tr>
<th>CODE Description</th>
<th>Tx Code BEFORE tx frame</th>
<th>MB RTR</th>
<th>Tx Code AFTER successful transmission</th>
<th>Comment</th>
</tr>
</thead>
</table>

The remote response frame will be transmitted unconditionally once, and then the code will automatically return to RANSWER (0b1010). The CPU can also write this code with the same effect. The remote response frame can be either a data frame or another remote request frame depending on the RTR bit value. See Matching process and Arbitration process for details.

**SRR — Substitute Remote Request**

Fixed recessive bit, used only in extended format. It must be set to one by the user for transmission (Tx Buffers) and will be stored with the value received on the CAN bus for Rx receiving buffers. It can be received as either recessive or dominant. If FlexCAN receives this bit as dominant, then it is interpreted as an arbitration loss.

1 = Recessive value is compulsory for transmission in extended format frames

0 = Dominant is not a valid value for transmission in extended format frames

**IDE — ID Extended Bit**

This field identifies whether the frame format is standard or extended.

1 = Frame format is extended

0 = Frame format is standard

**RTR — Remote Transmission Request**

This bit affects the behavior of remote frames and is part of the reception filter. See Table 45-24, Table 45-25, and the description of the RRS field in Control 2 register (CTRL2) for additional details.
If FlexCAN transmits this bit as '1' (recessive) and receives it as '0' (dominant), it is interpreted as an arbitration loss. If this bit is transmitted as '0' (dominant), then if it is received as '1' (recessive), the FlexCAN module treats it as a bit error. If the value received matches the value transmitted, it is considered a successful bit transmission.

1 = Indicates the current MB may have a remote request frame to be transmitted if MB is Tx. If the MB is Rx then incoming remote request frames may be stored.

0 = Indicates the current MB has a data frame to be transmitted. In Rx MB it may be considered in matching processes.

**NOTE**
When configuring CAN FD frames, the RTR bit must be negated.

**DLC** — Length of Data in Bytes

This 4-bit field is the length (in bytes) of the Rx or Tx data, which is located in offset 0x8 through 0xF of the MB space (see Table 45-23). In reception, this field is written by the FlexCAN module, copied from the DLC (Data Length Code) field of the received frame. In transmission, this field is written by the CPU and corresponds to the DLC field value of the frame to be transmitted. When RTR = 1, the frame to be transmitted is a remote frame and does not include the data field, regardless of the DLC field (see Table 45-26).

**TIME STAMP** — Free-Running Counter Time Stamp

This 16-bit field is a copy of the Free-Running Timer, captured for Tx and Rx frames at the time when the beginning of the Identifier field appears on the CAN bus.

**PRIO** — Local priority

This 3-bit field is used only when MCR[LPRIO_EN] is set, and it only makes sense for Tx mailboxes. These bits are not transmitted. They are appended to the regular ID to define the transmission priority. See Arbitration process.

**ID** — Frame Identifier

In standard frame format, only the 11 most significant bits (28 to 18) are used for frame identification in both receive and transmit cases. The 18 least significant bits are ignored. In extended frame format, all bits are used for frame identification in both receive and transmit cases.

**DATA BYTE 0 to 63** — Data Field

Up to sixty four bytes can be used for a data frame, depending on the size of payload selected for the message buffers.
For Rx frames, the data is stored as it is received from the CAN bus. DATA BYTE \((n)\) is valid only if \(n\) is less than DLC as shown in the table below.

<table>
<thead>

</tbody>
</table>

### 45.6.4 FlexCAN memory partition for CAN FD

When CAN FD is enabled, the FlexCAN RAM can be partitioned in blocks of 512 bytes. Each block can accommodate a number of message buffers which depends on the configuration provided by FDCTRL\[MBDSRn\] bit fields as shown in table below.

<table>
<thead>
<tr>
<th>RAM block</th>
<th>Number of MBs with 8 bytes (default range)</th>
<th>Size control bit field in FDCTRL register</th>
<th>Number of MBs of different sizes, per block</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0 to 31</td>
<td>MBDSR0</td>
<td>MBDSR0=00, 32 MBs with 8 bytes payload</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>MBDSR0=01, 21 MBs with 16 bytes payload</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>MBDSR0=10, 12 MBs with 32 bytes payload</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>MBDSR0=11, 7 MBs with 64 bytes payload</td>
</tr>
<tr>
<td>1</td>
<td>32 to 63</td>
<td>MBDSR1</td>
<td>MBDSR1=00, 32 MBs with 8 bytes payload</td>
</tr>
</tbody>
</table>
### Table 45-27. RAM partition

<table>
<thead>
<tr>
<th>RAM block</th>
<th>Number of MBs with 8 bytes (default range)</th>
<th>Size control bit field in FDCTRL register</th>
<th>Number of MBs of different sizes, per block</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td>MBDSR1=01, 21 MBs with 16 bytes payload</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>MBDSR1=10, 12 MBs with 32 bytes payload</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>MBDSR1=11, 7 MBs with 64 bytes payload</td>
<td></td>
</tr>
</tbody>
</table>

When payload sizes of 16, 32, or 64 bytes are configured in some or all RAM blocks, the total number of MBs and its respective number order may differ from the default configuration of 8 bytes. For example, suppose Block0 is configured to 8 bytes payload, Block1 to 16 bytes, then the following table indicates how the message buffers will be arranged in RAM.

### Table 45-28. RAM partition example

<table>
<thead>
<tr>
<th>RAM block</th>
<th>Payload size</th>
<th>Number of MBs in the RAM block</th>
<th>Message buffer range</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>FDCTRL[MBDSR0]=00, 8 bytes payload</td>
<td>32</td>
<td>0 to 31</td>
</tr>
<tr>
<td>1</td>
<td>FDCTRL[MBDSR1]=01, 16 bytes payload</td>
<td>21</td>
<td>32 to 52</td>
</tr>
</tbody>
</table>

### 45.6.5 FlexCAN message buffer memory map

The FlexCAN memory buffers are allocated in memory according to the tables below.

</table>
45.6.6  Rx FIFO structure

When MCR[RFEN] is set, the memory area from 0x80 to 0xDC (which is normally occupied by MBs 0–5) is used by the reception FIFO engine.

The region 0x80-0x8C contains the output of the FIFO which must be read by the CPU as a message buffer. This output contains the oldest message that has been received but not yet read. The region 0x90-0xDC is reserved for internal use of the FIFO engine.

An additional memory area, which starts at 0xE0 and may extend up to 0x2DC (normally occupied by MBs 6–37) depending on the CTRL2[RFFN] field setting, contains the ID filter table (configurable from 8 to 128 table elements) that specifies filtering criteria for accepting frames into the FIFO.

Out of reset, the ID filter table flexible memory area defaults to 0xE0 and extends only to 0xFC, which corresponds to MBs 6 to 7 for RFFN = 0, for backward compatibility with previous versions of FlexCAN.

The following shows the Rx FIFO data structure.

<table>
<thead>
<tr>
<th>Table 45-33. Rx FIFO structure</th>
</tr>
</thead>
<tbody>
<tr>
<td>31</td>

</tr>
<tr>
<td>0x88 to 0x24D4</td>
</tr>
<tr>
<td>0x2D8</td>
</tr>
<tr>
<td>0x2DC</td>
</tr>
</tbody>
</table>

Each ID filter table element occupies an entire 32-bit word and can be compounded by one, two, or four Identifier Acceptance Filters (IDAF) depending on the MCR[IDAM] field setting. The following figures show the IDAF indexation.
The following table shows the three different formats of the ID table elements. Note that all elements of the table must have the same format. See **Rx FIFO** for more information.

= Unimplemented or Reserved

**RTR** — Remote frame

This bit specifies if remote frames are accepted into the FIFO if they match the target ID.

1 = Remote frames can be accepted and data frames are rejected

0 = Remote frames are rejected and data frames can be accepted

**IDE** — Extended frame

Specifies whether extended or standard frames are accepted into the FIFO if they match the target ID.

1 = Extended frames can be accepted and standard frames are rejected

0 = Extended frames are rejected and standard frames can be accepted

**RXIDA** — Rx frame identifier (Format A)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, only the 11 most significant bits (29 to 19) are used for frame identification. In the extended frame format, all bits are used.

**RXIDB_0, RXIDB_1** — Rx frame identifier (Format B)

Specifies an ID to be used as acceptance criteria for the FIFO. In the standard frame format, the 11 most significant bits (a full standard ID) (29 to 19 and 13 to 3) are used for frame identification. In the extended frame format, all 14 bits of the field are compared to the 14 most significant bits of the received ID.

**RXIDC_0, RXIDC_1, RXIDC_2, RXIDC_3** — Rx frame identifier (Format C)
Specifies an ID to be used as acceptance criteria for the FIFO. In both standard and extended frame formats, all 8 bits of the field are compared to the 8 most significant bits of the received ID.

**IDHIT — Identifier acceptance filter hit indicator**

This 9-bit field indicates which identifier acceptance filter was hit by the received message that is in the output of the Rx FIFO. See Rx FIFO for more information.

46.2 Overview

The Keypad Port (KPP) is a 16-bit peripheral that can be used as a keypad matrix interface or as general purpose input/output (I/O).

The figure below shows the KPP block diagram. The KPP provides interface for the keypad matrix with 2-point contact or 3-point contact keys. The KPP is designed to simplify the software task of scanning a keypad matrix. With appropriate software support, the KPP is capable of detecting, debouncing, and decoding one or multiple keys pressed simultaneously on the keypad.

Figure 46-1. KPP Peripheral Block Diagram
46.2.1 Features

The KPP includes these distinctive features:

- Supports up to an 8 x 8 external key pad matrix
- Port pins can be used as general purpose I/O
- Open drain design
- Glitch suppression circuit design
- Multiple-key detection
- Long key-press detection
- Standby key-press detection
- Synchronizer chain clear
- Supports a 2-point and 3-point contact key matrix

46.2.2 Modes and Operations

This block supports the following modes:

- Run Mode-This is the normal functional mode in which the KPP can detect any key press event.
- Low Power Mode-The keypad can detect any key press even in low power modes (when there is no MCU clock).

46.3 Clocks

The table found here describes the clock sources for KPP.

Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

46.4 External Signals

There are several pins dedicated to the KPP. Keypads of any configuration up to eight rows and eight columns are supported through the software configuration of the peripheral pins. Any pins not used for the keypad are available as general purpose I/O. The registers are configured such that the pins can be treated as an I/O port up to 16 bits wide.

See the table below for the list of external signals.

</table>
46.4.1 Input Pins

Any of the 16 pins associated with the KPP can be configured as inputs by writing a "0" to the appropriate bits in the KPP_KDDR. Additionally, the least significant 8 bits (ROW inputs) corresponding to KPP_KDDR[KRDD] have internal pull-ups, which are enabled when the pin is used as an input.

46.4.2 Output Pins

Any of the 16 pins associated with the KPP can be configured as outputs by writing the appropriate bits in the KPP_KDDR to a "1". Additionally, the 8 most significant bits (15-8) can be designated as open drain outputs by writing a "1" to the appropriate bits in the KPP_KPCR. The lower 8 bits (7-0) are always in "totem pole" style, driven when configured as outputs.

See the table below.

<table>
<thead>
<tr>
<th>KPP_KDDR (15:8)</th>
<th>KPP_KPCR (15:8)</th>
<th>Pin Function</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Totem-Pole Output</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Open-Drain Output</td>
</tr>
</tbody>
</table>

**NOTE**

Totem pole capability should be provided for column pins. Totem pole configuration helps for a faster discharge of keypad capacitance when all columns need to be quickly brought to a "1" during the scan routine. With this configuration, delay between the scanning of two subsequent columns is reduced.

46.4.3 Generation of Transfer Error Signal on Peripheral Bus

If there is an access to an address which is not implemented, then the KPP asserts a transfer error signal on Peripheral Bus.
46.5 Functional Description

The Keypad Port (KPP) is designed to simplify the software task of scanning a keypad matrix. With appropriate software support and matrix organization, the KPP is capable of detecting, debouncing, and decoding one or more keys pressed simultaneously on the keypad.

Logic in the KPP is capable of detecting a key press even while the processor is in one of the low power standby modes provided that a low frequency reference clock (ipg_clk_32k) is on. The KPP may generate an Arm platform interrupt any time a key press or key release is detected. This interrupt is capable of forcing the processor out of a low power mode.

46.5.1 Keypad Matrix Construction

The KPP is designed to interface to a keypad matrix, which shorts the intersecting row and column lines together whenever a key is depressed. The interface is not optimized for any other switch configuration.

46.5.2 Keypad Port Configuration

The software must initialize the KPP for the size of the keypad matrix. Pins connected to the keypad columns should be configured as open-drain outputs. Pins connected to the keypad rows should be configured as inputs. On-chip, pull-up resistors should be implemented for active keypad rows.

In addition to enabled row inputs in the Keypad Control register, corresponding interrupt (depress or/and release) must also be enabled to generate an interrupt.

Discrete switches that are not part of the matrix may be connected to any unused row inputs. The second terminal of the discrete switch is connected to ground. The hardware detects closures of these switches without the need for software polling.

46.5.3 Keypad Matrix Scanning

Keypad scanning is performed by a software loop that walks a zero across each of the keypad columns, reading the value on the rows at each step. The process is repeated several times in succession, with the results of each pass optionally compared to those
from the previous pass. When several (3 or 4) consecutive scans yield the same key closures, a valid key press has been detected. Software then can decode exactly which switch was depressed and pass the value up to the next higher software layer.

The basic debouncing period, which must be defined in the software routine, may be controlled with an internal timer. The basic period is the period between the scan of two consecutive columns, so the debouncing time between two consecutive scans of the whole matrix shall be the number of columns multiplied by the basic period.

### 46.5.4 Keypad Standby

There is no need for the Arm platform to continually scan the keypad. Between key presses, the keypad can be left in a state that requires no software intervention until the next key press is detected. To place the keypad in a standby state, software should write all column outputs low. Row inputs are left enabled. At this point, the Arm platform can attend to other tasks or revert to a low power standby mode. The KPP will interrupt the Arm platform if any key is pressed.

Upon receiving a keypad interrupt, the Arm platform should set all the column strobes high, and begin a normal keypad scanning routine to determine which key was pressed. It is important that open-drain drivers be used when scanning to prevent a possible DC path between power and ground through two or more switches.

### 46.5.5 Glitch Suppression on Keypad Inputs

A glitch suppression circuit qualifies the keypad inputs to prevent noise from inadvertently interrupting the Arm platform. The circuit is a 4-state synchronizer clocked from a low frequency reference clock (ipg_clk_32k) source. This clock must continue to run in any low power mode where the keypad is a wake-up source, as the Arm platform interrupt is generated from the synchronized input. An interrupt is not generated until all four synchronizer stages have latched a valid key assertion. This guarantees the filtering out of any noise less than three clock periods in duration of a low frequency reference clock. Noise filtering of the duration between three to four clock periods cannot be guaranteed. The interrupt output is latched in an S-R latch and remains asserted until cleared by the software. The Set input of the latch is rising-edge clocked. See the figure below.
46.5.6 Multiple Key Closures

Using the key press and key release interrupts, the software can detect multiple keys or achieve n key rollover. The key scanning routine can be programmed accordingly (See Initialization/Application Information for more information).

The following figures illustrate the interface of a 2-contact keypad matrix with the KPP controller. With proper enabling of row lines and the performing scan-routine, multiple key presses can be detected. When keys present on the same row are pressed, corresponding row lines (multiple lines) become low when the column is driven low during a scan-routine. By reading the data-register, pressed keys can be detected.
Similarly, when keys present on same row line are pressed, the corresponding row line (only one line) becomes low when logic "0" is driven on the column line during a scan-routine.

**Figure 46-3. Multiple Key Presses on Same Column Line (Simplified View)**
**Figure 46-4. Multiple Key Presses on Same Row Line (Simplified View)**

**NOTE**
An n key rollover is a technique with which the system can recognize the order in which keys are pressed.

### 46.5.6.1 Ghost Key Problem and Correction

The KPP detects if one or multiple keys are pressed or released. In the case where a simple keypad matrix with two-contact switches is used, there is a chance of "ghost" key detection when three or more keys are pressed. This is a limitation imposed by such a keypad matrix.
As seen in Figure 46-5, three keys pressed simultaneously can cause a short between the column currently "scanned" by the software and another column. Depending on the location of the third key pressed, a "ghost" key press may be detected.

However, this can be corrected by using a keypad matrix that provides "ghost" key protection. Such a matrix implements a one-way "diode" at all keypad points between rows and columns. This way, the multiple pressing of three keys will not cause a short at a fourth key (see Figure 46-6).

![Figure 46-5. Decoding Wrong Three-Key-Presses](image-url)
46.5.7 3-Point Contact Keys Support

The KPP supports interfacing to a matrix consisting of 3-point contact keys. As shown in Figure 46-7, two points of such a key are connected to keypad lines, while a third point is connected to ground (low logic).

The keypad lines should be configured as input and a pull-up should to be present on these lines. When such a key is pressed, corresponding keypad lines go low and an interrupt is generated. There is no need to perform a scanning routine for identification of pressed key as it can be done by reading the keypad data-register. A limitation with such a matrix is that for every key at least one keypad row line should be used.

Figure 46-6. Matrix with "Ghost" Key Protections
46.6 Initialization/Application Information

46.6.1 Typical Keypad Configuration and Scanning Sequence

Perform the following steps to configure the keypad:

1. Enable the number of rows in the keypad (KPP_KPCR[KRE]).
2. Write 0s to KPP_KPDR[KCD].
3. Configure the keypad columns as open-drain (KPP_KPCR[KCO]).
4. Configure columns as output (KPP_KDDR[KCDD]) and rows as input (KPP_KDDR[KRDD]).
5. Clear the KPKD Status Flag and Synchronizer chain.
6. Set the KDIE control bit, and clear the KRIE control bit (avoid false release events).
7. (The system is now in standby mode, and awaiting a key press.)

46.6.2 Key Press Interrupt Scanning Sequence

Perform the following steps to perform a keypad scanning routine:

1. Disable both (depress and release) keypad interrupts.
2. Write 1s to KPP_KPDR[KCD], setting column data to 1s.
3. Configure columns as totem pole outputs (for quick discharging of keypad capacitance).
4. Configure columns as open-drain.
5. Write a single column to 0, and other columns to 1.
6. Sample row inputs and save data. Multiple key presses can be detected on a single column.
7. Repeat Steps 2-6 for remaining columns.
8. Return all columns to 0 in preparation for standby mode.
9. Clear KPKD and KPKR status bit(s) by writing to a "1"; set the KPKR synchronizer chain by writing a "1" to the KPP_KRSS register; and clear the KPKD synchronizer chain by writing a "1" to the KDSC register.
10. Re-enable the appropriate keypad interrupt(s) so that the KDIE detects a key hold condition, or the KRIE detects a key-release event.

46.6.3 Additional Comments

The order of key press detection can be done in software only. Therefore, the software may need to run the scan routines at very short intervals of time per the application's demands. The reason that such functionality cannot be put in the KPP is that the block is limited by the number of external pins.

For the keys that require a very precise order (such as game keys), individual GPIO pins may be more useful.

46.7 KPP Memory Map/Register Definition

The KPP contains four registers.

46.7.1 Keypad Control Register (KPP_KPCR)

The Keypad Control Register determines which of the eight possible column strobes are to be open drain when configured as outputs, and which of the eight row sense lines are considered in generating an interrupt to the core.

It is up to the programmer to ensure that pins being used for functions other than the keypad are properly disabled. The KPP_KPCR register is byte- or half-word-addressable.

<td>A key has been depressed</td>
</tr>
</tbody>
</table>

### 46.7.3 Keypad Data Direction Register (KPP_KDDR)

The bits in the KPP_KDDR control the direction of the keypad port pins. The upper eight bits in the register affect the pins designated as column strobes, while the lower eight bits affect the row sense pins. Setting any bit in this register configures the corresponding pin as an output. Clearing any bit in this register configures the corresponding port pin as an input. For the Keypad Row DDR, an internal pull-up is enabled if the corresponding bit is clear. This register is cleared by a reset, configuring all pins as inputs. The KPP_KDDR register is byte- or half-word addressable.

**NOTE**

When a pin is used as row pin for keypad purposes, all corresponding pull-ups should be enabled at the upper level (for example, IOMUX) when the bit in KRDD is cleared.
Address: 401F_C000h base + 4h offset = 401F_C004h

|       | 0  INPUT — ROWn pin configured as an input.  
|       | 1  OUTPUT — ROWn pin configured as an output. |

46.7.4 Keypad Data Register (KPP_KPDR)

This 16-bit register is used to access the column and row data. Data written to this register is stored in an internal latch, and for each pin configured as an output, the stored data is driven onto the pin. A read of this register returns the value on the pin for those bits configured as inputs. Otherwise, the value read is the value stored in the register.

The KPP_KPDR register is byte- or half-word addressable. This register is not initialized by a reset. Valid data should be written to this register before any bits are configured as outputs.

For LPI2C on this device, only LPI2C1 fully supports the 5 wires, while other instances (LPI2C2, ...) have only 2 wires.
47.2 Introduction

The LPI2C is a low power Inter-Integrated Circuit (I2C) module that supports an efficient interface to an I2C bus as a master and/or as a slave.

- The LPI2C implements logic support for standard-mode, fast-mode, fast-mode plus and ultra-fast modes of operation.
- The LPI2C is designed to use little CPU overhead, with DMA offloading of FIFO register accesses.
- The LPI2C can continue operating in stop modes if an appropriate clock is available.

The LPI2C module also complies with the System Management Bus (SMBus) Specification, version 2. From Wikipedia: The System Management Bus (abbreviated to SMBus or SMB) is a single-ended simple two-wire bus for the purpose of lightweight communication.
47.2.1 Features

The LPI2C supports:

- Standard, Fast, Fast+ and Ultra Fast modes are supported
- High speed mode (HS) in slave mode
- High speed mode (HS) in master mode, if SCL pin implements current source pull-up (device-specific)
• Multi-master support, including synchronization and arbitration. Multi-master means any number of master nodes can be present. Additionally, master and slave roles may be changed between messages (after a STOP is sent).
• Clock stretching: From Wikipedia: multiple nodes may be driving the lines simultaneously. If any node is driving the line low, then the line will be low. I2C nodes that are trying to transmit a logical one (i.e., letting the line float high) can detect this condition (line is low), and conclude that another node is active at the same time.
  • When node detection is used on the SCL line, this is called clock stretching, and it is used as a flow control mechanism for slaves.
  • When node detection is used on the SDA line, this is called arbitration, and it ensures that there is only one transmitter at a time.
• General call, 7-bit and 10-bit addressing
• Software reset, START byte and Device ID (also require software support)

The LPI2C master supports:
• Command/transmit FIFO of 4 words.
• Receive FIFO of 4 words.
• Command FIFO will wait for idle I2C bus before initiating transfer
• Command FIFO can initiate (repeated) START and STOP conditions and one or more master-receiver transfers
• STOP condition can be generated from command FIFO, or generated automatically when the transmit FIFO is empty
• Host request input to control the start time of an I2C bus transfer
• Flexible receive data match can generate interrupt on data match and/or discard unwanted data
• Flag and optional interrupt to signal Repeated START condition, STOP condition, loss of arbitration, unexpected NACK, and command word errors
• Supports configurable bus idle timeout and pin-stuck-low timeout

The LPI2C slave supports:
• Separate I2C slave registers to minimize software overhead because of master/slave switching
• Support for 7-bit or 10-bit addressing, address range, SMBus alert and general call address
• Transmit data register that supports interrupt or DMA requests
• Receive data register that supports interrupt or DMA requests
• Software-controllable ACK or NACK, with optional clock stretching on ACK/NACK bit
• Configurable clock stretching, to avoid transmit FIFO underrun and receive FIFO overrun errors
• Flag and optional interrupt at end of packet, STOP condition, or bit error detection

### 47.2.5 Wiring options

LPI2C can be used to implement 2-wire or 4-wire I²C serial busses.
Figure 47-5. 2-Wire scheme

Some applications can provide a lot of load and noise on the I²C bus; to ensure robust I²C operations, a 4-wire interface with the MCU can be used, splitting the 2 lines into inputs and outputs. Using a few transistors, resistors and diodes, designers can make their own inexpensive line drivers.

</tr>
</tbody>
</table>
| Software reset| • The LPI2C master implements a software reset bit in its Control Register. The MCR[RST] will reset all master logic and registers to their default state, except for the MCR itself.  
• The LPI2C slave implements a software reset bit in its Control Register. The SCR[RST] will reset all slave logic and registers to their default state, except for the SCR itself. |
| FIFO reset    | • The LPI2C master implements write-only control bits that reset the transmit FIFO (MCR[RTF]) and receive FIFO (MCR[RRF]). After a FIFO is reset, that FIFO is empty.  
• The LPI2C slave implements write-only control bits that reset the transmit data register (SCR[RTF]) and receive data register (SCR[RRF]). After a data register is reset, that data register is empty. |

47.3.2 Master Mode

The LPI2C master logic operates independently from the slave logic to perform all master mode transfers on the I2C bus.

47.3.2.1 Transmit and Command FIFO commands

The transmit FIFO stores command data to initiate the various I2C operations. The following operations can be initiated through commands in the transmit FIFO:

• START or Repeated START condition with address byte and expecting ACK or NACK.
• Transmit data (this is the default for zero extended byte writes to the transmit FIFO).
• Receive 1-256 bytes of data (can also be configured to discard receive data and not store in receive FIFO).
• STOP condition (can also be configured to send STOP condition when transmit FIFO is empty).
Multiple transmit and receive commands can be inserted between the START condition and STOP condition; transmit and receive commands must not be interleaved (to comply with the I2C specification). The receive data command and the receive data and discard commands can be interleaved, to ensure that only the desired received data is stored in the receive FIFO (or compared with the data match logic).

The LPI2C master will automatically transmit a NACK on the last byte of a receive data command unless the next command in the FIFO is also a receive data command. A NACK is also automatically transmitted if the transmit FIFO is empty when a receive data command completes.

The LPI2C master supports 10-bit addressing through a (repeated) START condition, followed by a transmit data byte containing the second address byte, followed by any number of data bytes with the master-transmit data.

A START or Repeated START condition that is expecting a NACK (for example, HS-mode master code) must be followed by a STOP or (repeated) START condition.

### 47.3.2.2 Master operations

Whenever the LPI2C is enabled, it monitors the I2C bus to detect when the I2C bus is idle (MSR[BBF]). The I2C bus is no longer considered idle if either SCL or SDA are low, and the I2C bus becomes idle if a STOP condition is detected or if a bus idle timeout is detected (as configured by MCFGR2[BUSIDLE]). After the I2C bus is idle, the transmit FIFO is not empty, and the host request is either asserted or disabled, then the LPI2C master will initiate a transfer on the I2C bus. This involves the following steps:

- Wait the bus idle time equal to (MCCR0[CLKLO] + 1) multiplied by the prescaler (MCFGR1[PRESCALE]).
- Transmit a START condition and address byte using the timing configuration in the Master Clock Configuration Register 0 (MCCR0); if a high speed mode transfer is configured, then the timing configuration from Master Clock Configuration Register 1 (MCCR1) is used instead.
- Perform master-transmit or master-receive transfers, as configured by the transmit FIFO.
- Transmit NACK on the last byte of a master-receive transfer, unless the next command in the transmit FIFO is also a receive data command and the transmit FIFO is not empty.
- Transmit a Repeated START or STOP condition as configured by the transmit FIFO and/or MCFGR1[AUTOSTOP]. A repeated START can change which timing configuration register is used.
When the LPI2C master is disabled (either due to MCR[MEN] being clear or automatically due to mode entry), the LPI2C will continue to empty the transmit FIFO until a STOP condition is transmitted. However, the LPI2C will no longer stall the I2C bus waiting for the transmit or receive FIFO, and after the transmit FIFO is empty, the LPI2C will generate a STOP condition automatically.

The LPI2C master can stall the I2C bus under certain conditions; this will result in SCL pulled low continuously on the first bit of a byte, until the condition is removed:

- LPI2C master is enabled and busy, the transmit FIFO is empty, and MCFGR1[AUTOSTOP] is clear.
- LPI2C master is enabled and receiving data, receive data is not being discarded (due to command or receive data match), and the receive FIFO is full.

### 47.3.2.3 Receive FIFO and Data Matching

The receive FIFO is used to store receive data during master-receiver transfers. Receive data can also be configured to discard receive data instead of storing in the receive FIFO; this is configured by the command word in the transmit FIFO.

Receive data supports a receive data match function that can match received data against one of two bytes or against a masked data byte. The data match function can also be configured to compare only the first one or two received data words since the last (repeated) START condition. Receive data that is already discarded due to the command word cannot cause the data match to set, and will delay the match on the first received data word until after the discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the MCFGR0[RDMO] control bit. When clearing the MCFGR0[RDMO] control bit following a data match, clear MCFGR0[RDMO] before clearing MSR[DMF], to allow all subsequent data to be received.

### 47.3.2.4 Timing Parameters

The following timing parameters can be configured by the LPI2C master. Parameters are configured separately for high speed mode (MCCR1) and other modes (MCCR0). This allows the high speed mode master code to be sent using the regular timing parameters, and then switch to the high speed mode timing (following a repeated START) until the next STOP condition.
The LPI2C master timing parameters in LPI2C functional clock cycles are configured as follows. They must be configured to meet the I2C timing specification for the required mode.

### Table 47-6. Timing Parameters

<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>hold time (repeated) START condition</td>
<td>tHD:STA</td>
<td>(SETHOLD +1) x (2 ^ PRESCALE)</td>
</tr>
<tr>
<td>LOW period of the SCL clock</td>
<td>tLOW</td>
<td>(CLKLO + 1) x (2 ^ PRESCALE)</td>
</tr>
<tr>
<td>HIGH period of the SCL clock</td>
<td>tHIGH</td>
<td>(CLKHI + 1 + SCL_LATENCY) x (2 ^ PRESCALE)</td>
</tr>
<tr>
<td>setup time for a repeated START condition or STOP condition</td>
<td>tSU:STA, tSU:STO</td>
<td>(SETHOLD + 1 + SCL_LATENCY) x (2 ^ PRESCALE)</td>
</tr>
<tr>
<td>data hold time</td>
<td>tHD:DAT</td>
<td>(DATAVD + 1) x (2 ^ PRESCALE)</td>
</tr>
<tr>
<td>data setup time</td>
<td>tSU:DAT</td>
<td>(SDA_LATENCY + 1) x (2 ^ PRESCALE)</td>
</tr>
<tr>
<td>bus free time between a STOP and START condition</td>
<td>tBUF</td>
<td>(CLKLO + 1 + SDA_LATENCY) x (2 ^ PRESCALE)</td>
</tr>
<tr>
<td>data valid time, data valid acknowledge time</td>
<td>tVD:DAT, tVD:ACK</td>
<td>(DATAVD + 1) x (2 ^ PRESCALE)</td>
</tr>
</tbody>
</table>

The latency parameters are defined in the following table, these parameters assume the risetime is less than one LPI2C functional clock cycle. The risetime depends on a number of factors, including the I2C bus loading and external pull-up resistor sizing. A larger risetime will increase the number of cycles that the signal takes to propagate through the synchronizer (and glitch filter), which increases the latency.

### Table 47-7. Synchronization Latency

<table>
<thead>
<tr>
<th>Timing Parameter</th>
<th>Timing Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCL_LATENCY</td>
<td>ROUNDDOWN ( (2 + FILTSCL + SCL_RISETIME) / (2 ^ PRESCALE) )</td>
</tr>
<tr>
<td>SDA_LATENCY</td>
<td>ROUNDDOWN ( (2 + FILTSDA + SDA_RISETIME) / (2 ^ PRESCALE) )</td>
</tr>
</tbody>
</table>

The following timing restrictions must be enforced to avoid unexpected START or STOP conditions on the I2C bus, or to avoid unexpected START or STOP conditions detected by the LPI2C master. The timing restrictions can be summarized as SDA cannot change when SCL is high outside of a transmitted (repeated) START or STOP condition.

### Table 47-8. LPI2C Timing Parameter Restrictions

</tr>
</tbody>
</table>

The timing parameters must be configured to meet the requirements of the I2C specification; this will depend on the mode being supported and the LPI2C functional clock frequency. When switching between two modes using the different clock configuration registers (for example, Fast and HS-mode), the PRESCALE factor must remain constant between the modes. Some example timing configurations are provided below.

Table 47-9. LPI2C Example Timing Configurations

1. Your specific device may not support all clock frequencies and baud rates; check the module instantiation and system information.

47.3.2.5 Error Conditions

The LPI2C master will monitor for errors while it is active, the following conditions will generate an error flag and block a new START condition from being sent, until the flag is cleared by software:
- A START or STOP condition is detected and is not generated by the LPI2C master (sets MSR[ALF]).
- Transmitting data on SDA and different values are being received (sets MSR[ALF]).
- NACK is detected when transmitting data, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- NACK is detected and is expecting ACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- ACK is detected and is expecting NACK for the address byte, and MCFGR1[IGNACK] is clear (sets MSR[NDF]).
- Transmit FIFO is requesting to transmit or receive data without a START condition (sets MSR[FEF]).
- SCL (or SDA if MCFGR1[TIMECFG] is set) is low for (MCFGR2[TIMELOW] * 256) prescaler cycles without a pin transition (sets MSR[PLTF]).

Software must respond to the MSR[PTLF] flag to terminate the existing command either cleanly (by clearing MCR[MEN]), or abruptly (by setting MCR[SWRST]).

The MCFGR2[BUSIDLE] field can be used to force the I2C bus to be considered idle when SCL and SDA remain high for (BUSIDLE+1) prescaler cycles. The I2C bus is normally considered idle when the LPI2C master is first enabled, but when BUSIDLE is configured greater than zero then SCL and/or SDA must be high for (BUSIDLE+1) prescaler cycles before the I2C bus is first considered idle.

### 47.3.2.6 Pin Configuration

- **Open-drain support:** The LPI2C master defaults to open-drain configuration of the SDA and SCL pins. Support for true open drain depends on the specific device, and requires the pins where LPI2C pins are muxed to support true open drain.
- **High Speed mode support:** Support for high speed mode also depends on the specific device, and requires the SCL pin to support the current source pull-up required in the I2C specification.
- **Ultra-Fast mode support:** The LPI2C master also supports the output-only push-pull function required for I2C ultra-fast mode using the SDA and SCL pins. Support for ultra-fast mode also requires the IGNACK bit to be set.
- **Push-pull 2-wire support:** A push-pull 2-wire configuration is also available to the LPI2C master that may support a partial high speed mode, if the LPI2C is the only master and all I2C pins on the bus are at the same voltage. This will configure the SCL pin as push-pull for every clock except the 9th clock pulse, to allow high speed mode compatible slaves to perform clock stretching. In this mode, the SDA pin is tristated for master-receive data bits and master-transmit ACK/NACK bits, and is configured as push-pull at other times. To avoid the risk of contention when SDA is
push-pull, the pin can be configured for open-drain operation, as part of the device-specific configuration.

- **Push-pull 4-wire support**: The push-pull 4-wire configuration separates the SCL input data and output data into separate pins, and separates the SDA input data and output data into separate pins. The SCL/SDA pins are used for input data; the SCLS/SDAS pins are used for output data, with configurable polarity. This simplifies external connections when connecting the LPI2C to the I2C bus through external level shifters or discrete components. When using this 4-wire configuration, the LPI2C master logic and LPI2C slave logic are not able to connect to separate I2C buses.

### 47.3.3 Slave Mode

To perform all slave mode transfers on the I2C bus, the LPI2C slave logic operates independently from the LPI2C master logic.

#### 47.3.3.1 Address Matching

The LPI2C slave can be configured:

- to match one of two addresses, using either 7-bit or 10-bit addressing modes for each address
- to match a range of addresses in either 7-bit or 10-bit addressing modes
- to match the General Call Address, and generate appropriate flags
- to match the SMBus Alert Address, and generate appropriate flags
- to detect the high speed mode master code, and to disable the digital filters and output valid delay time until the next STOP condition is detected

After a valid address is matched, the LPI2C slave will automatically perform slave-transmit or slave-receive transfers until:

- a NACK is detected (unless IGNACK is set)
- a bit error is detected (the LPI2C slave is driving SDA, but a different value is sampled)
- a (repeated) START or STOP condition is detected

#### 47.3.3.2 Transmit and Receive Data

- The Transmit and Receive Data registers are double-buffered and only update during a slave-transmit and slave-receive transfer, respectively.
The slave address that was received can be configured to be read from either the Receive Data register (for example, when using DMA to transfer data), or from the Address Status register.

The Transmit Data register can be configured to only request data after a slave-transmit transfer is detected, or to request new data whenever the Transmit Data register is empty.

The Transmit Data register should only be written when the Transmit Data flag is set.

The Receive Data register should only be read when the Received Data flag is set (or the Address Valid flag is set and RXCFG=1).

The Address Status register should only be read when the Address Valid flag is set.

### 47.3.3.3 Clock Stretching

The LPI2C slave supports many configurable options for when clock stretching is performed. The following conditions can be configured to perform clock stretching:

- During the 9th clock pulse of the address byte and the Address Valid flag is set.
- During the 9th clock pulse of a slave-transmit transfer and the Transmit Data flag is set.
- During the 9th clock pulse of a slave-receive transfer and the Receive Data flag is set.
- During the 8th clock pulse of an address byte or a slave-receive transfer and the Transmit ACK flag is set. In high speed mode, this is disabled.
- Clock stretching can also be extended for CLKHOLD cycles, to allow additional setup time to sample the SDA pin externally. In high speed mode, this is disabled.

Unless extended by the CLKHOLD configuration, clock stretching will extend for one peripheral bus clock cycle after SDA updates when clock stretching is enabled.

### 47.3.3.4 Timing Parameters

The LPI2C slave can configure the following timing parameters. These parameters are disabled when SCR[FILTEN] is clear, when SCR[FILTDZ] is set in Doze mode, and when LPI2C slave detects high speed mode. When disabled, the LPI2C slave is clocked directly from the I2C bus, and may not satisfy all timing requirements of the I2C specification (such as SDA minimum hold time in Standard/Fast mode).

- SDA data valid time from SCL negation to SDA update
- SCL hold time when clock stretching is enabled to increase setup time when sampling SDA externally
• SCL glitch filter time
• SDA glitch filter time

The LPI2C slave imposes the following restrictions on the timing parameters:

• FILTSDA must be configured to greater than or equal to FILTSCL (unless compensating for board level skew between SDA and SCL).
• DATAVD must be configured less than the minimum SCL low period.

### 47.3.3.5 Error Conditions

The LPI2C slave can detect the following error conditions:

• Bit error flag will set when the LPI2C slave is driving SDA, but samples a different value than what is expected.
• FIFO error flag will set due to a transmit data underrun or a receive data overrun. To eliminate the possibility of underrun and overrun occurring, enable clock stretching.
• FIFO error flag will also set due to an address overrun when RXCFG is set, otherwise an address overrun is not flagged. To eliminate the possibility of overrun occurring, enable clock stretching.

The LPI2C slave does not implement a timeout due to SCL and/or SDA being stuck low. If this detection is required, then the LPI2C master logic should be used and so software can reset the LPI2C slave when this condition is detected.

### 47.3.4 Interrupts and DMA Requests

Depending on the specific device, interrupts and DMA requests can be combined in some ways:

• The LPI2C master and slave interrupts may be combined
• The LPI2C master and slave transmit DMA requests may be combined
• The LPI2C master and slave receive DMA requests may be combined

#### 47.3.4.1 Master mode

The next table lists the master mode sources that can generate LPI2C master interrupts and LPI2C master transmit/receive DMA requests.
### Table 47-10. Master Interrupts and DMA Requests

• During a master-transmitter data byte, the master detected a NACK | Y | N | Y |
| ALF  | Arbitration Lost Flag | • The master lost arbitration due to a START/STOP condition detected at the wrong time  
• Or the master was transmitting data but received different data than the data that was transmitted | Y | N | Y |
| FEF  | FIFO Error Flag | The master is expecting a START condition in the Command FIFO, but the next entry in the Command FIFO is not a START condition | Y | N | Y |
| PLTF | Pin Low Timeout Flag | Pin low timeout is enabled and SCL (or SDA if configured) is low for longer than the configured timeout | Y | N | Y |
| DMF  | Data Match Flag | The received data matches the configured data match, but the received data is not discarded due to a command FIFO entry | Y | N | Y |
| MBF  | Master Busy Flag | LPI2C master is busy transmitting/receiving data | N | N | N |
| BBF  | Bus Busy Flag | LPI2C master is enabled and activity is detected on I2C bus, but a STOP condition has not been detected and a bus idle timeout (if enabled) has not occurred. | N | N | N |

#### 47.3.4.2 Slave mode

The next table lists the slave mode sources that can generate LPI2C slave interrupts and the LPI2C slave transmit/receive DMA requests.
### Table 47-11. Slave Interrupts and DMA Requests

<table>
<thead>
<tr>
<th>Flag</th>
<th>Name</th>
<th>Description</th>
<th>Can generate</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
<td></td>
<td>Interrupt?</td>
<td>DMA Request?</td>
<td>Low Power Wakeup?</td>
</tr>
<tr>
<td>TDF</td>
<td>Transmit Data Flag</td>
<td>Data can be written to the Slave Transmit Data Register (STDR)</td>
<td>Y</td>
<td>TX</td>
<td>Y</td>
</tr>
<tr>
<td>RDF</td>
<td>Receive Data Flag</td>
<td>Data can be read from the Slave Receive Data Register (SRDR)</td>
<td>Y</td>
<td>RX</td>
<td>Y</td>
</tr>
<tr>
<td>AVF</td>
<td>Address Valid Flag</td>
<td>Address can be read from the Slave Address Status Register (SASR)</td>
<td>Y</td>
<td>RX</td>
<td>Y</td>
</tr>
<tr>
<td>TAF</td>
<td>Transmit ACK Flag</td>
<td>ACK/NACK can be written to the Slave Transmit ACK Register (STAR)</td>
<td>Y</td>
<td>N</td>
<td>Y</td>
</tr>
<tr>
<td>RSF</td>
<td>Repeated Start Flag</td>
<td>Slave has detected an address match followed by a Repeated START condition</td>
<td>Y</td>
<td>N</td>
<td>Y</td>
</tr>
<tr>
<td>SDF</td>
<td>STOP Detect Flag</td>
<td>Slave has detected an address match followed by a STOP condition</td>
<td>Y</td>
<td>N</td>
<td>Y</td>
</tr>
<tr>
<td>BEF</td>
<td>Bit Error Flag</td>
<td>Slave was transmitting data, but received different data than what was transmitted</td>
<td>Y</td>
<td>N</td>
<td>Y</td>
</tr>
</tbody>
</table>
| FEF  | FIFO Error Flag        | • Transmit data underrun  
• Receive data overrun  
• Address status overrun (when Receive Data Configuration SCFG1[RXCFG] = 1, )  
FEF flag can only set when clock stretching is disabled. | Y            | N            | Y             |
| AM0F | Address Match 0 Flag   | Slave detected an address match with SAMR[ADDR0] field                     | Y            | N            | N             |
| AM1F | Address Match 1 Flag   | Slave detected an address match with SAMR[ADDR1] field or using an address range | Y            | N            | N             |
| GCF  | General Call Flag      | Slave detected an address match with the General Call address               | Y            | N            | N             |
| SARF | SMBus Alert Response Flag | Slave detected an address match with the SMBus Alert address                  | Y            | N            | N             |
| SBF  | Slave Busy Flag        | LPI2C slave is busy receiving an address byte or is transmitting/receiving data | N            | N            | N             |
| BBF  | Bus Busy Flag          | LPI2C slave is enabled and a START condition is detected on I2C bus, but a STOP condition has not been detected | N            | N            | N             |
47.3.5 Peripheral Triggers

The connection of the LPI2C peripheral triggers to other peripherals depend upon the specific device being used.

<table>
<thead>
<tr>
<th>Trigger</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Master Output Trigger</td>
<td>The LPI2C master generates an output trigger that can be connected to other peripherals on the device. The master output trigger asserts on both a Repeated START or STOP condition, and the master output trigger remains asserted for one cycle of the LPI2C functional clock divided by the prescaler.</td>
</tr>
<tr>
<td>Slave Output Trigger</td>
<td>The LPI2C slave generates an output trigger that can be connected to other peripherals on the device. The slave output trigger asserts on both a Repeated START or STOP condition that occurs after a slave address match, and the slave output trigger remains asserted until the next slave SCL pin negation.</td>
</tr>
<tr>
<td>Input Trigger</td>
<td>To control the start of a LPI2C bus transfer, the LPI2C input trigger can be selected instead of the HREQ input. The input trigger is synchronized and to be detected, the input trigger must assert for at least 2 cycles of the LPI2C functional clock divided by the PRESCALE configuration. When the LPI2C is busy, the HREQ input (and therefore the input trigger) is ignored.</td>
</tr>
</tbody>
</table>

47.4 Memory Map and Registers

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| PLTF  | Will set when the SCL and/or SDA input is low for more than PINLOW cycles (Pin Low Timeout, MCFGR3[PINLOW]), even when the LPI2C master is idle.  
  • Software is responsible for resolving the pin low condition.  
  • Pin Low Timeout Flag cannot be cleared as long as the pin low timeout continues.  
  • Before the LPI2C can initiate a START condition, the Pin Low Timeout Flag must be cleared.  
  0b - Pin low timeout has not occurred or is disabled  
  1b - Pin low timeout has occurred |
| 12    | FIFO Error Flag  
  Detects an attempt to send or receive data without first generating a (repeated) START condition. This can occur if the transmit FIFO underflows when the AUTOSTOP bit is set. When FIFO Error Flag is set, the LPI2C master will send a STOP condition (if busy), and will not initiate a new START condition until FIFO Error Flag has been cleared.  
  0b - No error  
  1b - Master sending or receiving data without a START condition |
| 11    | Arbitration Lost Flag  
  Set:  
  • if the LPI2C master transmits a logic one and detects a logic zero on the I2C bus  
  • or if the LPI2C master detects a START or STOP condition while the LPI2C master is transmitting data  
  When the Arbitration Lost Flag sets, the LPI2C master will release the I2C bus (go idle), and the LPI2C master will not initiate a new START condition until the Arbitration Lost Flag has been cleared.  
  0b - Master has not lost arbitration  
  1b - Master has lost arbitration |
| 10    | NACK Detect Flag  
  Set if the LPI2C master detects a NACK when transmitting an address or data. When set, the master will transmit a STOP condition and will not initiate a new START condition until NACK Detect Flag has been cleared. If a NACK is expected for a given address (as configured by the command word), then the NACK Detect Flag will set if a NACK is not generated.  
  0b - Unexpected NACK was not detected  
  1b - Unexpected NACK was detected |
| 9     | STOP Detect Flag  
  Set when the LPI2C master generates a STOP condition.  
  0b - Master has not generated a STOP condition  
  1b - Master has generated a STOP condition |
| 8     | End Packet Flag  
  Set when the LPI2C master generates either a repeated START condition or a STOP condition. Does not set when the master first generates a START condition.  
  0b - Master has not generated a STOP or Repeated START condition  
  1b - Master has generated a STOP or Repeated START condition |
| 7-2   | Reserved |
| 1     | Receive Data Flag

<tbody>
<tr>
<td>RDMO</td>
<td>When enabled, all received data that does not cause the Data Match Flag (MSR[DMF]) to set is discarded. After the Data Match Flag is set, the RDMO configuration is ignored. When disabling RDMO, clear RDMO before clearing the Data Match Flag, to ensure that no receive data is lost.  0b - Received data is stored in the receive FIFO  1b - Received data is discarded unless the the Data Match Flag (MSR[DMF]) is set</td>
</tr>
</tbody>
</table>
| 8     | Circular FIFO Enable  
When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO will be emptied as normal, but after the LPI2C master is idle and the transmit FIFO is empty, then the read pointer value will be restored from the temporary register. This will cause the contents of the transmit FIFO to be cycled through repeatedly. If AUTOSTOP is set, then a STOP condition will be sent whenever the transmit FIFO is empty and the read pointer is restored.  0b - Circular FIFO is disabled  1b - Circular FIFO is enabled |
| 7-3   | Reserved |
| 2     | Host Request Select  
Selects the source of the host request input. When host request input is enabled, the Host Request Select field should remain static (the Host Request Select should not change).  0b - Host request input is pin HREQ  1b - Host request input is input trigger |
| 1     | Host Request Polarity  
Configures the polarity of the host request input pin. When host request input is enabled, the Host Request Polarity field should remain static (Host Request Polarity should not change).  0b - Active low  1b - Active high |
| 0     | Host Request Enable  
When enabled, the LPI2C master will only initiate a START condition if the host request input is asserted and the bus is idle. A repeated START is not affected by the host request.  0b - Host request input is disabled  1b - Host request input is enabled |

### Master Configuration Register 2 (MCFGR2)

#### Field | Function
--- | ---
| 111b - 4-pin push-pull mode (inverted outputs) | 23-19 
| Reserved | 18-16 
| Match Configuration | MATCFG
- Configures the condition that will cause the DMF to set.
  - 000b - Match is disabled
  - 001b - Reserved
  - 010b - Match is enabled (1st data word equals MATCH0 OR MATCH1)
  - 011b - Match is enabled (any data word equals MATCH0 OR MATCH1)
  - 100b - Match is enabled (1st data word equals MATCH0 AND 2nd data word equals MATCH1)
  - 101b - Match is enabled (any data word equals MATCH0 AND next data word equals MATCH1)
  - 110b - Match is enabled (any data word AND MATCH1 equals MATCH0 AND MATCH1)
| Reserved | 15-11 
| TimeCFG | 10 
| Timeout Configuration | TIMECFG
- 0b - Pin Low Timeout Flag will set if SCL is low for longer than the configured timeout
- 1b - Pin Low Timeout Flag will set if either SCL or SDA is low for longer than the configured timeout
| IgnACK | 9 
| When set, the received NACK field is ignored and assumed to be ACK. IGNACK bit is required to be set in Ultra-Fast Mode. | IGNACK
- 0b - LPI2C Master will receive ACK and NACK normally
- 1b - LPI2C Master will treat a received NACK as if it (NACK) was an ACK
| AUTOSTOP | 8 
| Automatic STOP Generation | AUTOSTOP
- When enabled, a STOP condition is generated whenever the LPI2C master is busy and the transmit FIFO is empty. The STOP condition can also be generated using a transmit FIFO command.
- 0b - No effect
- 1b - STOP condition is automatically generated whenever the transmit FIFO is empty and the LPI2C master is busy
| Reserved | 7-3 
| Prescaler | PRESCALE
- Configures the clock prescaler used for all LPI2C master logic, except for the digital glitch filters.
  - 000b - Divide by 1
  - 001b - Divide by 2
  - 010b - Divide by 4

<td>19-16</td>
<td>FILTSCl</td>
</tr>
</tbody>
</table>

FILTSDA

- Configures the I2C master digital glitch filters for SDA input.
  - A configuration of 0 will disable the glitch filter
  - Glitches equal to or less than FILTSDA cycles long will be filtered out and ignored
  - The latency through the glitch filter is equal to FILTSDA cycles, and must be configured to be less than the minimum SCL low or high period
  - The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is automatically bypassed in High Speed mode

Table continues on the next page...
### Field and Function

<table>

<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-12</td>
<td>Reserved</td>
</tr>
<tr>
<td>11-0</td>
<td>BUSIDLE</td>
</tr>
</tbody>
</table>

**BUSIDLE**
- Configures the bus idle timeout period in clock cycles.
- If both SCL and SDA are high for longer than BUSIDLE cycles, then the I2C bus is assumed to be idle and the master can generate a START condition.
- When Bus Idle Timeout is set to zero, the Bus Idle Timeout is disabled.

### 47.4.1.14 Master Clock Configuration Register 1 (MCCR1)

#### 47.4.1.14.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>MCCR1</td>
<td>50h</td>
</tr>
</tbody>
</table>
47.4.1.14.2 Function
The MCCR1 cannot be changed when the I2C master is enabled and is used for high speed mode transfers. The separate clock configuration for high speed mode allows arbitration to take place in Fast mode (with timing configured by MCCR0), before switching to high speed mode (with timing configured by MCCR1).

<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>MTDR</td>
<td>60h</td>
</tr>
</tbody>
</table>

#### 47.4.1.17.2 Function

- An 8-bit write to the CMD field will store the data in the Command FIFO, but does not increment the FIFO write pointer.
- An 8-bit write to the DATA field will zero extend the CMD field, unless the CMD field has been written separately since the last FIFO write; it (the 8-bit write) also increments the FIFO write pointer.
- A 16-bit or 32-bit will write both the CMD and DATA fields and increment the FIFO.

#### 47.4.1.17.3 Diagram

|        | 0b - Transmit ACK/NACK is not required  
|        | 1b - Transmit ACK/NACK is required  
| 2 AVF | Address Valid Flag  
|        | Address Valid Flag is cleared by reading the address status register. When Receive Data Configuration (SCFGR1[RXCFG]) is set, the Address Valid Flag is also cleared by reading the Receive Data register.  
|        | 0b - Address Status Register is not valid  
|        | 1b - Address Status Register is valid  
| 1 RDF | Receive Data Flag  
|        | Receive Data Flag is cleared by reading the receive data register. When Receive Data Configuration (SCFGR1[RXCFG]) is set, the Receive Data Flag is not cleared when reading the Receive Data register and if AVF is set.  
|        | 0b - Receive data is not ready  
|        | 1b - Receive data is ready  

Table continues on the next page...
Transmit Data Flag is cleared by writing the Transmit Data register. When Transmit Flag Configuration (TXCFG) is clear, and if a NACK or Repeated START or STOP condition is detected, then Transmit Data Flag is also cleared.

0b - Transmit data not requested
1b - Transmit data is requested

*Table continues on the next page...*
### Field | Function
--- | ---
FILTSDA | Configures the I2C slave digital glitch filters for SDA input.
- A configuration of 0 will disable the glitch filter
- Glitches equal to or less than FILTSDA cycles long will be filtered out and ignored
- The latency through the glitch filter is equal to FILTSDA+3 cycles, and must be configured to be less than the minimum SCL low or high period
- The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is disabled in high speed mode

| Field | Function |
--- | --- |
23-20 | Reserved |
19-16 | Glitch Filter SCL
FILTSCL | Configures the I2C slave digital glitch filters for SCL input.
- A configuration of 0 will disable the glitch filter
- Glitches equal to or less than FILTSCL cycles long will be filtered out and ignored
- The latency through the glitch filter is equal to FILTSCL+3 cycles, and must be configured to be less than the minimum SCL low or high period
- The glitch filter cycle count is not affected by the PRESCALE configuration, and the glitch filter cycle count is disabled in high speed mode |
15-14 | Reserved |
13-8 | Data Valid Delay
DATAVD | Configures the SDA data valid delay time for the I2C slave, and is equal to FILTSCL+DATAVD+3 cycles.
- The data valid delay must be configured to be less than the minimum SCL low period
- The I2C slave data valid delay time is not affected by the PRESCALE configuration, and the I2C slave data valid delay time is disabled in high speed mode |
7-4 | Reserved |
3-0 | Clock Hold Time
CLKHOLD | Configures the minimum clock hold time for the I2C slave, when clock stretching is enabled.
- The minimum hold time is equal to CLKHOLD+3 cycles
- The I2C slave clock hold time is not affected by the PRESCALE configuration, and the I2C slave clock hold time is disabled in high speed mode |

### 47.4.1.25 Slave Address Match Register (SAMR)

#### 47.4.1.25.1 Offset

| Register | Offset |
--- | --- |
SAMR | 140h |

#### 47.4.1.25.2 Function

The SAMR should only be written when the I2C Slave is disabled.

        1b - Received Address (RADDR) is not valid |
| 13-11 | Reserved |
| 10-0  | Received Address |
| RADDR | The Received Address updates whenever the AMF is set; the AMF is cleared by reading the Slave Address Status register.  
        • In 7-bit mode, the address byte is store in RADDR[7:0]  
        • In 10-bit mode, the first address byte is { 11110, RADDR[10:9], RADDR[0] } and the second address byte is RADDR[8:1]. The R/W bit is therefore always stored in RADDR[0] |

### 47.4.1.27 Slave Transmit ACK Register (STAR)

#### 47.4.1.27.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>STAR</td>
<td>154h</td>
</tr>
</tbody>
</table>
47.4.1.27.2 Function
The Slave Transmit ACK Register can only be written when the ACK SCL Stall bit is set in Slave Configuration Register 1 (SCFGR1[ACKSTALL]).
- The ACKSTALL bit will enable clock stretching during the ACK/NACK bit slot, and during this time, the STAR register can be written by software.
- The logic ensures that the clock stretching continues for at least 1 bus clock cycle after the STAR register is updated.
- This clock stretching time can be extended more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>STDR</td>
<td>160h</td>
</tr>
</tbody>
</table>

47.4.1.28.2 Function

Clock stretching (enabled or disabled) affects when the transmit data is transferred. The TXDSTALL bit will enable clock stretching during the 1st data bit of a slave-transmit transfer.

- **If clock stretching is enabled** (TXDSTALL=1), then the transmit data transfer is stalled until the Slave Transmit register (STDR) is updated. Clock stretching is extended by at least 1 bus clock cycle after the Slave Transmit Data Register (STDR) is updated, and clock stretching can be delayed even more using the Clock Hold Time field (SCFGR2[CLKHOLD], Slave Configuration Register 2).
- **If clock stretching is disabled** (TXDSTALL=0), then the transmit data should be written before the start of the slave-transmit transfer; otherwise (i.e., if the transmit data is not written before the start of the slave-transmit transfer), the FIFO Error Flag (SSR[FEF]) will be set.

48.2 Introduction

48.2.1 Overview

The LPSPI is a low power Serial Peripheral Interface (SPI) module that supports an efficient interface to an SPI bus as a master and/or a slave. The LPSPI can continue operating in stop modes provided an appropriate clock is available and is designed for low CPU overhead with DMA offloading of FIFO register accesses.
48.2.2 Features

The LPSPI supports the following features:

- Word size = 32 bits
- Command/transmit FIFO of 16 words.
- Receive FIFO of 16 words.
- Host request input can be used to control the start time of an SPI bus transfer.

48.2.3 Block Diagram

![Block Diagram of LPSPI](image)

48.2.4 Modes of operation

The LPSPI module supports the chip modes described in the following table.
### Table 48-2. Chip modes supported by the LPSPI module

<table>

### 48.3 Functional description
48.3.1 Clocking and Resets

48.3.1.1 Functional clock
The LPSPI functional clock is asynchronous to the bus clock and if it remains enabled in low power modes then LPSPI can perform SPI bus transfers and low power wakeups in both master and slave modes. The LPSPI divides the functional clock by a prescaler and the resulting frequency must be at least two times faster than the SPI external clock (LPSPI_SCK) frequency.

48.3.1.2 External clock
The LPSPI shift register is clocked directly by the LPSPI_SCK clock that is either generated internally in master mode or supplied externally in slave mode.

48.3.1.3 Bus clock
The bus clock is only used for bus accesses to the control and configuration registers. The bus clock frequency must be sufficient to support the data bandwidth requirements of the LPSPI registers, including FIFOs.

48.3.1.4 Chip reset
The logic and registers for the LPSPI are reset to their default state on a chip reset.

48.3.1.5 Software reset
The LPSPI implements a software reset bit in the Control Register. The CR[RST] will reset all logic and registers to their default state, except for the CR itself.

48.3.1.6 FIFO reset
The LPSPI implements write-only control bits that resets the transmit/command FIFO (CR[RTF] and receive FIFO (CR[RRF]). A FIFO is empty after being reset.
48.3.2 Master Mode

48.3.2.1 Transmit and Command FIFO

The transmit and command FIFO is a combined FIFO that includes both transmit data and command words. Command words are stored to the transmit/command FIFO by writing the transmit command register. Transmit data words are stored to the transmit/command FIFO by writing the transmit data register.

When a command word is at the top of the transmit/command FIFO, the following actions can occur:

- If the LPSPI is between frames, the command word is pulled from the FIFO and controls all subsequent transfers.
- If the LPSPI is busy and either the existing CONT bit is clear or the new CONTC value is clear, the SPI frame will complete at the end of the existing word, ignoring the FRAMESZ configuration. The command word is then pulled from the FIFO and controls all subsequent transfers (or until the next update to the command word).
- If the LPSPI is busy and the existing CONT bit is set and the new CONTC value is set, the command word is pulled from the FIFO during the last LPSPI_SCK pulse of the existing frame (based on FRAMESZ configuration) and the frame continues using the new command value for the rest of the frame (or until the next update to the command word). When CONTC is set, only the lower 24-bits of the command word are updated.

The current state of the existing command word can be read by reading the transmit command register. It requires at least three LPSPI functional clock cycles for the transmit command register to update after it is written (assuming an empty FIFO) and the LPSPI must be enabled (CR[MEN] is set).

Writing the transmit command register does not initiate a SPI bus transfer, unless the TXMSK bit is set. When TXMSK is set, a new command word will not be loaded until the end of the existing frame (based on FRAMESZ configuration) and the TXMSK bit will be cleared at the end of the transfer.

The following table describes the attributes that are controlled by the command word.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Modify During Transfer</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPOL</td>
<td>Configures polarity of the LPSPI_SCK pin. Any change of CPOL value will cause a transition on the LPSPI_SCK pin.</td>
<td>N</td>
</tr>
<tr>
<td>CPHA</td>
<td>Configures clock phase of transfer.</td>
<td>N</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
## Table 48-3. LPSPI Command Word in Master Mode (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Modify During Transfer</th>
</tr>
</thead>
<tbody>
<tr>
<td>PRESCALE</td>
<td>Configures prescaler used to divide the LPSPI functional clock to generate the timing parameters of the SPI bus transfer. Changing PRESCALE in conjunction with PCS allows the LPSPI to connect to different slave devices at different frequencies.</td>
<td>N</td>
</tr>
<tr>
<td>PCS</td>
<td>Configures which LPSPI_PCS asserts for the transfer, the polarity of LPSPI_PCS is static and configured by PCSPOL. If PCSCFG is set, then PCS[3:2] should not be selected.</td>
<td>N</td>
</tr>
<tr>
<td>LSBF</td>
<td>Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted/received first.</td>
<td>Y</td>
</tr>
<tr>
<td>BYSW</td>
<td>Enables byte swap on each 32-bit word when transmitting and receiving data. Can be useful when interfacing to devices that organize data as big endian.</td>
<td>Y</td>
</tr>
<tr>
<td>CONT</td>
<td>Configures for a continuous transfer that keeps PCS asserted between frames (as configured by FRAMESZ). A new command word is required to cause PCS to negate. Also supports changing the command word at frame size boundaries.</td>
<td>Y</td>
</tr>
<tr>
<td>CONTC</td>
<td>Indicates that this is a new command word for the existing continuous transfer. CONTC bit is ignored when not written to the transmit/command FIFO on a frame boundary.</td>
<td>Y</td>
</tr>
<tr>
<td>RXMSK</td>
<td>Masks the receive data and does not store to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.</td>
<td>Y</td>
</tr>
<tr>
<td>TXMSK</td>
<td>Masks the transmit data, so that data is not pulled from transmit FIFO and the output data pin is tristated (unless configured by OUTCFG). Useful for half-duplex transfers.</td>
<td>Y</td>
</tr>
<tr>
<td>WIDTH</td>
<td>Configures the number of bits shifted on each LPSI_SCK pulse.</td>
<td>Y</td>
</tr>
<tr>
<td></td>
<td>• 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• 2-bit and 4-bit transfers are useful for interfacing to QuadSPI memory devices, and only support half-duplex data formats (at least one of TXMSK or RXMSK must also be set).</td>
<td></td>
</tr>
<tr>
<td>FRAMESZ</td>
<td>Configures the frame size in number of bits equal to (FRAMESZ + 1).</td>
<td>Y</td>
</tr>
<tr>
<td></td>
<td>• The minimum frame size is 8 bits.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported.</td>
<td></td>
</tr>
</tbody>
</table>

The LPSPI initiates a SPI bus transfer when data is written to the transmit FIFO, the HREQ pin is asserted (or disabled) and the LPSPI is enabled. The SPI bus transfer uses the attributes configured in the transmit command register and timing parameters from the clock configuration register to perform the transfer. The SPI bus transfer ends once the FRAMESZ configuration is reached, or at the end of a word when a new transmit
command word is at the top of the transmit/command FIFO. The HREQ input is only checked the next time the LPSPI goes idle (completes the current transfer and transmit/command register is empty).

The transmit/command FIFO also supports a Circular FIFO feature. This allows the LPSPI master to (periodically) repeat a short data transfer that can fit within the transmit/command FIFO, without requiring additional FIFO accesses. When the circular FIFO is enabled, the current state of the FIFO read pointer is saved and the status flags do not update. Once the transmit/command FIFO is considered empty and the LPSPI is idle, the FIFO read pointer is restored with the saved version, so the contents of the transmit/command FIFO are not permanently pulled from the FIFO while circular FIFO mode is enabled.

### 48.3.2.2 Receive FIFO and Data Match

The receive FIFO is used to store receive data during SPI bus transfers. When RXMSK is set, receive data is discarded instead of storing in the receive FIFO.

The receive data is written to the receive FIFO at the end of the frame. During a multiple word or continuous transfer, the receive data is also written to the receive FIFO at the same time as new transmit data is read from the transmit FIFO. If the transmit FIFO is empty during a continuous transfer, the receive data is only written to the receive FIFO after the transmit FIFO is written or the command register is written to end the frame.

Receive data supports a receive data match function that can match received data against one of two words or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame. Receive data that is already discarded due to RXMSK bit cannot cause the data match to set and will delay the match on first received data word until after all discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the CFGR0[RDMO] control bit. When clearing the CFGR0[RDMO] control bit following a data match, clear CFGR0[RDMO] before clearing SR[DMF] to allow all subsequent data to be received.

### 48.3.2.3 Timing Parameters

The following table lists the timing parameters that are used for all SPI bus transfers, these timing parameters are relative to the LPSPI functional clock divided by the PRESCALE configuration. Although the Clock Configuration Register cannot be
changed when the LPSPI is busy, the PRESCALE configuration can be altered between transfers using the command register, to support interfacing to different slave devices at different frequencies.

Table 48-4. LPSPI Timing Parameters

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
<th>Min</th>
<th>Max</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCKDIV</td>
<td>Configures the LPSPI_SCK clock period to (SCKDIV+2) cycles. When configured to an odd number of cycles, the first half of the LPSPI_SCK cycle is one cycle longer than the second half.</td>
<td>0 (2 cycles)</td>
<td>255 (257 cycles)</td>
</tr>
<tr>
<td>DBT</td>
<td>Configures the minimum delay between PCS negation and the next PCS assertion to (DBT + 2) cycles. When the command word is updated between transfers, there is a minimum of (DBT/2)+1 cycles between the command word update and any change on LPSPI_PCS pins.</td>
<td>0 (2 cycles)</td>
<td>255 (257 cycles)</td>
</tr>
<tr>
<td>DBT</td>
<td>Configures the delay during a continuous transfer between the last SCK edge of a frame and the first SCK edge of the continuing frame to (DBT + 1) cycles. This is useful where the external slave requires a large delay between different words of a SPI bus transfer.</td>
<td>0 (1 cycle)</td>
<td>255 (256 cycles)</td>
</tr>
<tr>
<td>PCSSCK</td>
<td>Configures the minimum delay between PCS assertion and the first SCK edge to (PCSSCK + 1) cycles.</td>
<td>0 (1 cycle)</td>
<td>255 (256 cycles)</td>
</tr>
<tr>
<td>SCKPCS</td>
<td>Configures the minimum delay between the last SCK edge and the PCS assertion to (SCKPCS + 1) cycles.</td>
<td>0 (1 cycle)</td>
<td>255 (256 cycles)</td>
</tr>
</tbody>
</table>

**48.3.2.4 Pin Configuration**

The LPSPI_SIN and LPSPI_SOUT pins can be configured via the PINCFG configuration to swap directions or even support half-duplex transfers on the same pin.
The OUTCFG configuration can be used to determine if output data pin (eg: LPSPI_SOUT) will tristate when the LPSPI_PCS is negated, or if it will simply retain the last value. When configuring for half-duplex transfers using the same data pin in single bit transfer mode, or any transfer in 2-bit and 4-bit transfer modes, then the output data pins must be configured to tristate when LPSPI_PCS is negated.

The PCSCFG configuration is used to disable LPSPI_PCS[3:2] functions and to use them for quad-data transfers. This option must be enabled when performing quad-data transfers.

### 48.3.3 Slave Mode

LPSPI slave mode uses the same shift register and logic as the master mode, but does not use the clock configuration register and the transmit command register must remain static during SPI bus transfers.

### 48.3.3.1 Transmit and Command FIFO

The transmit command register should be initialized before enabling the LPSPI in slave mode, although the command register will not update until after the LPSPI is enabled. Once enabled, the transmit command register should only be changed if the LPSPI is idle. The following table lists how the command register functions in slave mode.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CPOL</td>
<td>Configures polarity of the external LPSPI_SCK input.</td>
</tr>
<tr>
<td>CPHA</td>
<td>Configures clock phase of transfer.</td>
</tr>
<tr>
<td>PRESCALE</td>
<td>Configures LPSPI functional clock prescaler.</td>
</tr>
<tr>
<td>PCS</td>
<td>Configures which LPSPI_PCS is used, the polarity of LPSPI_PCS is static and configured by PCSPOL. If PCSCFG is set, then PCS[3:2] should not be selected.</td>
</tr>
<tr>
<td>LSBF</td>
<td>Configures if LSB (bit 0) or MSB (bit 31 for a 32-bit word) is transmitted/received first.</td>
</tr>
<tr>
<td>BYSW</td>
<td>Enables byte swap on each 32-bit word when transmitting and receiving data. Can be useful when interfacing to devices that organize data as big endean.</td>
</tr>
<tr>
<td>CONT</td>
<td>When set, only the first FRAMSZ bits will be transmitted/received by the LPSPI.</td>
</tr>
<tr>
<td>CONTC</td>
<td>CONTC bit is reserved in slave mode.</td>
</tr>
<tr>
<td>RXMSK</td>
<td>Masks the receive data and does not store to the receive FIFO or perform receive data matching. Useful for half-duplex transfers or to configure which fields are compared during receive data matching.</td>
</tr>
<tr>
<td>TXMSK</td>
<td>Masks the transmit data, so that data is not pulled from transmit FIFO and the output data pin is tristated (unless configured by OUTCFG). Useful for half-duplex transfers.</td>
</tr>
<tr>
<td>WIDTH</td>
<td>Configures the number of bits shifted on each LPSPI_SCK pulse.</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
### Table 48-5. LPSPI Command Word in Slave Mode (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• 1-bit transfers support traditional SPI bus transfers in either half-duplex or full-duplex data formats.</td>
</tr>
<tr>
<td></td>
<td>• 2-bit and 4-bit transfers are useful for interfacing to QuadSPI memory devices, and only support half-duplex data formats (at least one of TXMSK or RXMSK must also be set).</td>
</tr>
<tr>
<td>FRAMESZ</td>
<td>Configures the frame size in number of bits equal to (FRAMESZ + 1).</td>
</tr>
<tr>
<td></td>
<td>• The minimum frame size is 8 bits.</td>
</tr>
<tr>
<td></td>
<td>• If the frame size is larger than 32 bits, then the frame is divided into multiple words of 32-bits; each word is loaded from the transmit FIFO and stored in the receive FIFO separately.</td>
</tr>
<tr>
<td></td>
<td>• If the size of the frame is not divisible by 32, then the last load of the transmit FIFO and store of the receive FIFO will contain the remainder bits. For example, a 72-bit transfer will consist of 3 words: the 1st and 2nd words are 32-bit, and the 3rd word is 8-bit.</td>
</tr>
<tr>
<td></td>
<td>• The minimum word size is 2 bits; a frame size of 33 bits (or similar) is not supported.</td>
</tr>
</tbody>
</table>

The transmit FIFO must be filled with transmit data before the LPSPI_PCS input asserts, otherwise the transmit error flag will set.

#### 48.3.3.2 Receive FIFO and Data Match

The receive FIFO is used to store receive data during SPI bus transfers. When RXMSK is set, receive data is discarded instead of storing in the receive FIFO.

Receive data supports a receive data match function that can match received data against one of two words or against a masked data word. The data match function can also be configured to compare only the first one or two received data words since the start of the frame. Receive data that is already discarded due to RXMSK bit cannot cause the data match to set and will delay the match on first received data word until after all discarded data is received. The receiver match function can also be configured to discard all receive data until a data match is detected, using the CFGR0[RDMO] control bit. When clearing the CFGR0[RDMO] control bit following a data match, clear CFGR0[RDMO] before clearing SR[DMF] to allow all subsequent data to be received.

#### 48.3.3.3 Clocked Interface

The LPSPI supports interfacing to external masters that provide only clock and data pins (LPSPI_PCS is not required). This requires using CPHA=1, configuring the LPSPI_PCS input to be always asserted (configure PCSPOL) and setting the AUTOPCS bit. When AUTOPCS is set, a minimum of 4 LPSPI functional clock cycles (divided by PRESCALE configuration) is required between the last LPSPI_SCK edge of one word and the first LPSPI_SCK edge of the next word.
### 48.3.4 Interrupts and DMA Requests

The following table illustrates the status flags that can generate the LPSPI interrupt and LPSPI transmit/receive DMA requests.

#### Table 48-6. LPSPI Interrupts and DMA Requests

<table>

<td>N</td>
<td>N</td>
<td>N</td>
</tr>
</tbody>
</table>
### 48.3.5 Peripheral Triggers

The connection of the LPSPI peripheral triggers with other peripherals are device specific.

#### 48.3.5.1 Output Triggers

The LPSPI generates two output triggers that can be connected to other peripherals on the device. The frame output trigger asserts at the end of each frame (when PCS negates) and remains asserted until PCS next asserts. The word output trigger asserts at the end of each received word and remains asserted for one LPSPI_SCK period.

#### 48.3.5.2 Input Trigger

The LPSPI input trigger can be selected in place of the LPSPI_HREQ input to control the start of a LPSPI bus transfer. The input trigger is synchronized and must assert for at least two cycles of the LPSPI functional clock divided by the PRESCALE configuration to be detected. Note that the LPSPI_HREQ input (and therefore the input trigger) is ignored when the LPSPI is busy.

### 48.4 Memory Map and Registers

<td>Receive Data Match Only</td>
</tr>
</tbody>
</table>
### Field Function

- **RDMO**
  - When Receive Data Match Only is enabled, all received data that does not cause the Data Match Flag (SR[DMF]) to set is discarded.
  - Receive Data Match Only bit should be set when the LPSPI is idle and the Data Match Flag is clear.
  - After the Data Match Flag (DMF) is set, the Receive Data Match Only bit configuration is ignored.
  - When disabling RDMO and to ensure that no receive data is lost, before clearing the Data Match Flag, first clear Receive Data Match Only (RDMO).

  - 0b - Received data is stored in the receive FIFO as in normal operations
  - 1b - Received data is discarded unless the Data Match Flag (DMF) is set

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>RDMO</td>
<td>When Receive Data Match Only is enabled, all received data that does not cause the Data Match Flag (SR[DMF]) to set is discarded. Normally, this is used in master mode to ensure no receive data is lost. However, when disabling RDMO and Data Match Only, data is discarded unless the Data Match Flag (DMF) is set.</td>
</tr>
</tbody>
</table>

- **CIRFIFO**
  - Circular FIFO Enable
    - When enabled, the transmit FIFO read pointer is saved to a temporary register. The transmit FIFO will be emptied as it normally is, but after the LPSPI is idle and the transmit FIFO is empty, then the read pointer value will be restored from the temporary register. This restoring of the read pointer will cause the contents of the transmit FIFO to be cycled through repeatedly.
    - 0b - Circular FIFO is disabled
    - 1b - Circular FIFO is enabled

- **HRSEL**
  - Host Request Select
    - Selects the source of the host request input. When the host request function is enabled with the LPSPI_HREQ pin, the LPSPI_PCS[1] function is disabled.
    - 0b - Host request input is the LPSPI_HREQ pin
    - 1b - Host request input is the input trigger

- **HRPOL**
  - Host Request Polarity
    - Configures the polarity of the host request pin.
    - 0b - Active low
    - 1b - Active high

- **HREN**
  - Host Request Enable
    - When enabled in master mode, the LPSPI will only start a new SPI bus transfer if the host request input is asserted. When the LPSPI is busy, the host request input is ignored.
    - 0b - Host request is disabled
    - 1b - Host request is enabled

### 48.4.1.9 Configuration Register 1 (CFGR1)

#### 48.4.1.9.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>CFGR1</td>
<td>24h</td>
</tr>
</tbody>
</table>

#### 48.4.1.9.2 Function

The CFGR1 should only be written when the LPSPI is disabled.
48.4.1.9.3  Diagram

### Bits 31-28

**Reserved**

### Bits 27

**PCSCFG**

Peripheral Chip Select Configuration

If performing 4-bit transfers, the Peripheral Chip Select Configuration bit must be set.

- 0b - PCS[3:2] are enabled
- 1b - PCS[3:2] are disabled

### Bits 26

**OUTCFG**

Output Config

Configures if the output data is tristated between accesses (LPSPI_PCS is negated).

- 0b - Output data retains last value when chip select is negated
- 1b - Output data is tristated when chip select is negated

### Bits 25-24

**PINCFG**

Pin Configuration

Configures which pins are used for input and output data during single bit transfers.

- 00b - SIN is used for input data and SOUT is used for output data
- 01b - SIN is used for both input and output data
- 10b - SOUT is used for both input and output data
- 11b - SOUT is used for input data and SIN is used for output data

### Bits 23-19

**Reserved**

### Bits 18-16

**MATCFG**

Match Configuration

Configures the condition that will cause the DMF to set.

**NOTE:** Syntax: * is boolean AND, + is boolean OR

- 000b - Match is disabled
- 001b - Reserved
- 010b - 010b - Match is enabled, if 1st data word equals MATCH0 OR MATCH1, i.e., (1st data word = MATCH0 + MATCH1)

Table continues on the next page...
### Field | Function
--- | ---
011b - 011b | Match is enabled, if any data word equals MATCH0 OR MATCH1, i.e., (any data word = MATCH0 + MATCH1)
100b - 100b | Match is enabled, if 1st data word equals MATCH0 AND 2nd data word equals MATCH1, i.e., [(1st data word = MATCH0) * (2nd data word = MATCH1)]
101b - 101b | Match is enabled, if any data word equals MATCH0 AND the next data word equals MATCH1, i.e., [(any data word = MATCH0) * (next data word = MATCH1)]
110b - 110b | Match is enabled, if (1st data word AND MATCH1) equals (MATCH0 AND MATCH1), i.e., [(1st data word * MATCH1) = (MATCH0 * MATCH1)]
111b - 111b | Match is enabled, if (any data word AND MATCH1) equals (MATCH0 AND MATCH1), i.e., [(any data word * MATCH1) = (MATCH0 * MATCH1)]

| Field | Function |
--- | --- |
15-12 | Reserved |
11-8 | Peripheral Chip Select Polarity |
PCSPOL | Configures the polarity of each Peripheral Chip Select pin. |
| | 0000b - The Peripheral Chip Select pin PCSx is active low |
| | 0001b - The Peripheral Chip Select pin PCSx is active high |
7-4 | Reserved |
3 | No Stall |
NOSTALL | In master mode, the LPSPI will stall transfers when the transmit FIFO is empty or when the receive FIFO is full, ensuring that no transmit FIFO underrun or receive FIFO overrun can occur. Setting the No Stall bit will disable this functionality. |
| | 0b - Transfers will stall when the transmit FIFO is empty or the receive FIFO is full |
| | 1b - Transfers will not stall, allowing transmit FIFO underruns or receive FIFO overruns to occur |
2 | Automatic PCS |
AUTOPCS | For correct operations, the LPSPI slave normally requires the PCS to negate between frames. Setting the Automatic PCS bit will cause the LPSPI to generate an internal PCS signal at the end of each transfer word when the Clock Phase bit TCR[CPHA] = 1. |
| | When the Automatic PCS bit is set, the SCK must remain idle for at least 4 LPSPI functional clock cycles (divided by the Prescaler Value TCR[PRESCALE] configuration) between each word, to ensure correct operations |
| | In master mode, the Automatic PCS bit is ignored |
| | 0b - Automatic PCS generation is disabled |
| | 1b - Automatic PCS generation is enabled |
1 | Sample Point |
SAMPLE | When set, the LPSPI master will sample the input data on a delayed LPSPI_SCK edge, which improves the setup time when sampling data. |
| | The input data setup time in master mode with delayed LPSPI_SCK edge is equal to the input data setup time in slave mode |
| | In slave mode, the SAMPLE bit is ignored |
| | 0b - Input data is sampled on SCK edge |
| | 1b - Input data is sampled on delayed SCK edge |
0 | Master Mode |
MASTER | Configures the LPSPI in master or slave mode. The Master Mode bit directly controls the direction of the LPSPI_SCK and LPCPI_PCS pins. |
| | 0b - Slave mode |
| | 1b - Master mode |

48.4.1.15.2 Function

Writes to either the Transmit Command Register or Transmit Data Register will push the data into the transmit FIFO, in the order that the data are written. Command Register writes will be tagged and cause the command register to update, after that entry reaches the top of the FIFO. This allows changes to the command word and the transmit data itself to be interleaved. Changing the command word will cause all subsequent SPI bus transfers to be performed using the new command word.

- **In master mode**, writing a new command word does not initiate a new transfer, unless TXMSK is set. Transfers are initiated by transmit data in the transmit FIFO, or by a new command word (with TXMSK set). Hardware will clear TXMSK when the LPSPI_PCS negates.
- **In master mode**, if the command word is changed before an existing frame has completed, then the existing frame will terminate and the command word will then update. The command word can be changed during a continuous transfer, if CONTC of the new command word is set and the command word is written on a frame size boundary.
- **In slave mode**, the command word should be changed only when the LPSPI is idle and there is no SPI bus transfer.

**Avoid register reading problems:** Reading the Transmit Command Register will return the current state of the command register. Reading the Transmit Command Register at the same time that the Transmit Command Register is loaded from the transmit FIFO, can return an incorrect Transmit Command Register value. It is recommended:

- to either read the Transmit Command Register when the transmit FIFO is empty,
- or to read the Transmit Command Register more than once and then compare the returned values.
