49.2 Introduction

49.2.1 Features

Features of the LPUART module include:
- Full-duplex, standard non-return-to-zero (NRZ) format
- Programmable baud rates (13-bit modulo divider) with configurable oversampling ratio from 4x to 32x
- Transmit and receive baud rate can operate asynchronous to the bus clock:
  - Baud rate can be configured independently of the bus clock frequency
  - Supports operation in Stop modes
• Interrupt, DMA or polled operation:
  • Transmit data register empty and transmission complete
  • Receive data register full
  • Receive overrun, parity error, framing error, and noise error
  • Idle receiver detect
  • Active edge on receive pin
  • Break detect supporting LIN
  • Receive data match
• Hardware parity generation and checking
• Programmable 7-bit, 8-bit, 9-bit or 10-bit character length
• Programmable 1-bit or 2-bit stop bits
• Three receiver wakeup methods:
  • Idle line wakeup
  • Address mark wakeup
  • Receive data match
• Automatic address matching to reduce ISR overhead:
  • Address mark matching
  • Idle line address matching
  • Address match start, address match end
• Optional 13-bit break character generation / 11-bit break character detection
• Configurable idle length detection supporting 1, 2, 4, 8, 16, 32, 64 or 128 idle characters
• Selectable transmitter output and receiver input polarity
• Hardware flow control support for request to send (RTS) and clear to send (CTS) signals
• Selectable IrDA 1.4 return-to-zero-inverted (RZI) format with programmable pulse width
• Independent FIFO structure for transmit and receive
  • Separate configurable watermark for receive and transmit requests
  • Option for receiver to assert request after a configurable number of idle characters if receive FIFO is not empty

49.2.2 Modes of operation

49.2.2.1 Stop mode

The LPUART will remain functional during Stop mode, provided the CTRL[DOZEEN] bit is clear and the asynchronous transmit and receive clock remain enabled. The LPUART can generate an interrupt or DMA request to cause a wakeup from Stop mode.
If the LPUART is disabled in Stop mode, then it can generate a wakeup via the STAT[RXEDGIF] flag if the receiver detects an active edge.

### 49.2.2.2 Wait mode

The LPUART can be configured to Stop in Wait modes, when the CTRL[DOZEEN] bit is set. The transmitter and receiver will finish transmitting/receiving the current word.

### 49.2.4 Block diagram

The following figure shows the transmitter portion of the LPUART.
Figure 49-1. LPUART transmitter block diagram

The following figure shows the receiver portion of the LPUART.
49.3 Functional description

The LPUART supports full-duplex, asynchronous, NRZ serial communication and comprises a baud rate generator, transmitter, and receiver block. The transmitter and receiver operate independently, although they use the same baud rate generator. The following describes each of the blocks of the LPUART.

49.3.1 Clocking and Resets

Table 49-2. Clocks

<table>
<thead>
<tr>

</tr>
</tbody>
</table>

49.3.2 Baud rate generation

A 13-bit modulus counter in the baud rate generator derives the baud rate for both the receiver and the transmitter. The value from 1 to 8191 written to BAUD[SBR] determines the baud clock divisor for the asynchronous LPUART baud clock. The baud rate clock drives the receiver, while the transmitter is driven by a bit clock which is generated from baud rate clock divided by the over sampling ratio. Depending on the over sampling ratio, the receiver has an acquisition rate of 4 to 32 samples per bit time.

![Diagram of LPUART baud rate generation](image)

**Figure 49-3. LPUART baud rate generation**

Baud rate generation is subject to two sources of error:

- Integer division of the asynchronous LPUART baud clock may not give the exact target frequency.
- Synchronization with the asynchronous LPUART baud clock can cause phase shift.

The baud rate generation is a free-running counter that continues whenever the transmitter or receiver is enabled. The transmitter bit clock continues whenever the transmitter is enabled, each transmitted character will align to the next edge of the transmit bit clock.
49.3.3 Transmitter functional description

This section describes the overall block diagram for the LPUART transmitter, as well as specialized functions for sending break and idle characters.

The transmitter output (TXD) idle state defaults to logic high, CTRL[TXINV] is cleared following reset. The transmitter output is inverted by setting CTRL[TXINV]. The transmitter is enabled by setting the CTRL[TE] bit. This queues a preamble character that is one full character frame of the idle state. The transmitter then remains idle until data is available in the transmit data buffer. Programs store data into the transmit data buffer by writing to the DATA register.

The central element of the LPUART transmitter is the transmit shift register that is 9-bit to 13 bits long depending on the setting in the CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] control bits. For the remainder of this section, assume CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SBNS] are cleared, selecting the normal 8-bit data mode. In 8-bit data mode, the shift register holds a start bit, eight data bits, and a stop bit. When the transmit shift register is available for a new character, the value waiting in the transmit data register is transferred to the shift register, synchronized with the baud rate clock, and the transmit data register empty (STAT[TDRE]) status flag is set to indicate another character may be written to the transmit data buffer at the DATA register.

If no new character is waiting in the transmit data buffer after a stop bit is shifted out the TXD pin, the transmitter sets the transmit complete flag and enters an idle mode, with TXD high, waiting for more characters to transmit.

Writing 0 to CTRL[TE] does not immediately disable the transmitter. The current transmit activity in progress must first be completed (that could include a data character, idle character or break character), although the transmitter will not start transmitting another character.

49.3.3.1 Send break and queued idle

The CTRL[SBK] bit sends break characters originally used to gain the attention of old teletype receivers. Break characters are a full character time of logic 0, 9-bit to 12-bit times including the start and stop bits. A longer break of 13-bit times can be enabled by setting STAT[BRK13]. Normally, a program would wait for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, write 1, and then write 0 to the CTRL[SBK] bit. This action queues a break character to be sent as soon as the shifter is available. If CTRL[SBK] remains 1 when the queued break moves into the shifter, synchronized to the baud rate clock, an additional break character is queued. When the LPUART is the receiving device, a break character is received as 0s in all data bits and a framing error (STAT[FE] = 1) is detected.
A break character can also be transmitted by writing to the DATA register with bit 13 set and the data bits clear. This supports transmitting the break character as part of the normal data stream and also allows the DMA to transmit a break character.

When idle-line wakeup is used, a full character time of idle (logic 1) is needed between messages to wake up any sleeping receivers. Normally, a program would wait for STAT[TDRE] to become set to indicate the last character of a message has moved to the transmit shifter, then write 0 and then write 1 to the CTRL[TE] bit. This action queues an idle character to be sent as soon as the shifter is available. As long as the character in the shifter does not finish while CTRL[TE] is cleared, the LPUART transmitter never actually releases control of the TXD pin.

An idle character can also be transmitted by writing to the DATA register with bit 13 set and the data bits also set. This supports transmitting the idle character as part of the normal data stream and also allows the DMA to transmit an idle character.

The length of the break character is affected by the STAT[BRK13], CTRL[M], CTRL[M7], BAUD[M10] and BAUD[SNBS] bits as shown below.

49.3.3.2 Hardware flow control

The transmitter supports hardware flow control by gating the transmission with the value of CTS_B. If the clear-to-send operation is enabled, the character is transmitted when CTS_B is asserted. If CTS_B is deasserted in the middle of a transmission with characters remaining in the transmitter data buffer, the character in the shift register is sent and TXD remains in the mark state until CTS_B is reasserted. The CTS_B pin must assert for longer than one bit period to guarantee a new transmission is started when the transmitter is idle with data to send.

If the clear-to-send operation is disabled, the transmitter ignores the state of CTS_B.

The transmitter's CTS_B signal can also be enabled even if the same LPUART receiver's RTS_B signal is disabled.

49.3.3.3 Transceiver driver enable

The transmitter can use RTS_B as an enable signal for the driver of an external transceiver. See Transceiver driver enable using RTS_B for details. If the request-to-send operation is enabled, when a character is placed into an empty transmitter data buffer, RTS_B asserts one bit time before the start bit is transmitted. RTS_B remains asserted for the whole time that the transmitter data buffer has any characters. RTS_B deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. Transmitting a break character also asserts RTS_B, with the same assertion and deassertion timing as having a character in the transmitter data buffer.

The transmitter's RTS_B signal asserts only when the transmitter is enabled. However, the transmitter's RTS_B signal is unaffected by its CTS_B signal. RTS_B will remain asserted until the transfer is completed, even if the transmitter is disabled mid-way through a data transfer.

49.3.3.4 Transceiver driver enable using RTS_B

RS-485 is a multiple drop communication protocol in which the LPUART transceiver's driver is 3-stated unless the LPUART is driving. The RTS_B signal can be used by the transmitter to enable the driver of a transceiver. The polarity of RTS_B can be matched to the polarity of the transceiver's driver enable signal.
In the figure, the receiver enable signal is asserted. Another option for this connection is to connect RTS_B to both DE and RE_B. The transceiver's receiver is disabled while driving. A pullup can pull RXD to a non-floating value during this time. This option can be refined further by operating the LPUART in single wire mode, freeing the RXD pin for other uses.

### 49.3.4 Receiver functional description

In this section, the receiver block diagram is a guide for the overall receiver functional description. Next, the data sampling technique used to reconstruct receiver data is described in more detail. Finally, different variations of the receiver wakeup function are explained.

The receiver input is inverted by setting STAT[RXINV]. The receiver is enabled by setting the CTRL[RE] bit. Character frames consist of a start bit of logic 0, seven to ten data bits (msb or lsb first), and one or two stop bits of logic 1. For information about 7-bit, 9-bit or 10-bit data mode, refer to Data Modes. For the remainder of this discussion, assume the LPUART is configured for normal 8-bit data mode.

After receiving the stop bit into the receive shifter, and provided the receive data register is not already full, the data character is transferred to the receive data register and the receive data register full (STAT[RDRF]) status flag is set. If [RDRF] was already set indicating the receive data register (buffer) was already full, the overrun (OR) status flag is set and the new data is lost. Because the LPUART receiver is double-buffered, the program has one full character time after [RDRF] is set before the data in the receive data buffer must be read to avoid a receiver overrun.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. Refer to Interrupts and status flags for details about flag clearing.
49.3.4.1 Data sampling technique

The LPUART receiver supports a configurable oversampling rate of between 4× and 32× of the baud rate clock for sampling. The receiver starts by taking logic level samples at the oversampling rate times the baud rate to search for a falling edge on the RXD serial data input pin. A falling edge is defined as a logic 0 sample after three consecutive logic 1 samples. The oversampling baud rate clock divides the bit time into 4 to 32 segments from 1 to OSR (where OSR is the configured oversampling ratio). When a falling edge is located, three more samples are taken at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to make sure this was a real start bit and not merely noise. If at least two of these three samples are 0, the receiver assumes it is synchronized to a received character. If another falling edge is detected before the receiver is considered synchronized, the receiver restarts the sampling from the first segment.

The receiver then samples each bit time, including the start and stop bits, at (OSR/2), (OSR/2)+1, and (OSR/2)+2 to determine the logic level for that bit. The logic level is interpreted to be that of the majority of the samples taken during the bit time. If any sample in any bit time, including the start and stop bits, in a character frame fails to agree with the logic level for that bit, the noise flag (STAT[NF]) is set when the received character is transferred to the receive data buffer.

When the LPUART receiver is configured to sample on both edges of the baud rate clock, the number of segments in each received bit is effectively doubled (from 1 to OSR×2). The start and data bits are then sampled at OSR, OSR+1 and OSR+2. Sampling on both edges of the clock must be enabled for oversampling rates of 4× to 7× and is optional for higher oversampling rates.

The falling edge detection logic continuously looks for falling edges. If an edge is detected, the sample clock is resynchronized to bit times (unless resynchronization has been disabled). This improves the reliability of the receiver in the presence of noise or mismatched baud rates. It does not improve worst case analysis because some characters do not have any extra falling edges anywhere in the character frame.

In the case of a framing error, provided the received character was not a break character, the sampling logic that searches for a falling edge is filled with three logic 1 samples so that a new start bit can be detected almost immediately.

49.3.4.2 Receiver wakeup operation

Receiver wakeup and receiver address matching is a hardware mechanism that allows an LPUART receiver to ignore the characters in a message intended for a different receiver.
During receiver wakeup, all receivers evaluate the first character(s) of each message, and as soon as they determine the message is intended for a different receiver, they write logic 1 to the receiver wake up control bit (CTRL[RWU]). When CTRL[RWU] and STAT[RWUID] bit are set, the status flags associated with the receiver, with the exception of the idle bit, STAT[IDLE], are inhibited from setting, thus eliminating the software overhead for handling the unimportant message characters. At the end of a message, or at the beginning of the next message, all receivers automatically force CTRL[RWU] to 0 so all receivers wake up in time to look at the first character(s) of the next message.

During receiver address matching, the address matching is performed in hardware and the LPUART receiver will ignore all characters that do not meet the address match requirements.

49.3.4.2.1 Idle-line wakeup

When wake is cleared, the receiver is configured for idle-line wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a full character time of the idle-line level. The CTRL[M], CTRL[M7] and BAUD[M10] control bit selects 7-bit to 10-bit data mode and the BAUD[SBNS] bit selects 1-bit or 2-bit stop bit number that determines how many bit times of idle are needed to constitute a full character time, 9 to 13 bit times because of the start and stop bits.

When CTRL[RWU] is one and STAT[RWUID] is 0, the idle condition that wakes up the receiver does not set the STAT[IDLE] flag. The receiver wakes up and waits for the first data character of the next message that sets the STAT[RDRF] flag and generates an interrupt if enabled. When STAT[RWUID] is 1, any idle condition sets the STAT[IDLE] flag and generates an interrupt if enabled, regardless of whether CTRL[RWU] is 0 or 1.

The idle-line type (CTRL[ILT]) control bit selects one of two ways to detect an idle line. When CTRL[ILT] is cleared, the idle bit counter starts after the start bit so the stop bit and any logic 1s at the end of a character count toward the full character time of idle. When CTRL[ILT] is set, the idle bit counter does not start until after the stop bit time, so the idle detection is not affected by the data in the last character of the previous message.

49.3.4.2.2 Address-mark wakeup

When CTRL[WAKE] is set, the receiver is configured for address-mark wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a logic 1 in the most significant bit of the received character. When parity is enabled, the second most significant bit is used for address-mark wakeup.

Address-mark wakeup allows messages to contain idle characters, but requires one bit be reserved for use in address frames. The logic 1 in the most significant bit (or second most significant bit when parity is enabled) of an address frame clears the CTRL[RWU] bit and sets the STAT[RDRF] flag. In this case, the character with the address-mark bit is received even though the receiver was sleeping during most of this character time.

49.3.4.2.3 Data match wakeup

When CTRL[RWU] is set, CTRL[WAKE] is set and BAUD[MATCFG] equals 11, the receiver is configured for data match wakeup. In this mode, CTRL[RWU] is cleared automatically when the receiver detects a character that matches MATCH[MA1] field when BAUD[MAEN1] is set, or that matches MATCH[MA2] when BAUD[MAEN2] is set.
49.3.4.2.4  Address Match operation

Address match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 00. In this function, a character received by the RXD pin with a logic 1 in the most significant bit (or second most significant bit when parity is enabled) is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters received with a logic 0 in the most significant bit (or second most significant bit when parity is enabled) are considered to be data associated with the address and are transferred to the receive data buffer. If no marked address match occurs then no transfer is made to the receive data buffer, and all following characters with logic zero in the most significant bit (or second most significant bit when parity is enabled) are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Address match operation functions in the same way for both MATCH[MA1] and MATCH[MA2] fields.

- If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, a marked address is compared only with the associated match register field and data is transferred to the receive data buffer only on a match.

- If BAUD[MAEN1] and BAUD[MAEN2] are asserted, a marked address is compared with both match registers and data is transferred only on a match with either of the MATCH[MA1] or MATCH[MA2] fields.

49.3.4.2.5  Idle Match operation

Idle match operation is enabled when the BAUD[MAEN1] or BAUD[MAEN2] bit is set and BAUD[MATCFG] is equal to 01. In this function, the first character received by the RXD pin after an idle line condition is considered an address and is compared with the associated MATCH[MA1] or MATCH[MA2] field. The character is only transferred to the receive buffer, and STAT[RDRF] is set, if the comparison matches. All subsequent characters are considered to be data associated with the address and are transferred to the receive data buffer until the next idle line condition is detected. If no address match occurs then no transfer is made to the receive data buffer, and all following frames until the next idle condition are also discarded. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

Idle match operation functions in the same way for both MATCH[MA1] or MATCH[MA2] fields.
• If only one of BAUD[MAEN1] and BAUD[MAEN2] is asserted, the first character after an idle line is compared only with the associated match register and data is transferred to the receive data buffer only on a match.

• If BAUD[MAEN1] and BAUD[MAEN2] are asserted, the first character after an idle line is compared with both MATCH[MA1] or MATCH[MA2] fields and data is transferred only on a match with either of the fields.

49.3.4.2.6 Match On Match Off operation

Match on, match off operation is enabled when both BAUD[MAEN1] and BAUD[MAEN2] are set and BAUD[MATCFG] is equal to 10. In this function, a character received by the RXD pin that matches MATCH[MA1] is received and transferred to the receive buffer, and STAT[RDRF] is set. All subsequent characters are considered to be data and are also transferred to the receive data buffer, until a character is received that matches MATCH[MA2] field. The character that matches MATCH[MA2] and all following characters are discarded; this continues until another character that matches MATCH[MA1] is received. If both the BAUD[MAEN1] and BAUD[MAEN2] bits are negated, the receiver operates normally and all data received is transferred to the receive data buffer.

NOTE
Match on, match off operation requires both BAUD[MAEN1] and BAUD[MAEN2] to be asserted.

49.3.4.3 Hardware flow control

To support hardware flow control, the receiver can be programmed to automatically deassert and assert RTS_B.

• RTS_B remains asserted until the transfer is complete, even if the transmitter is disabled midway through a data transfer. See Transceiver driver enable using RTS_B for more details.
• If the receiver request-to-send functionality is enabled, the receiver automatically deasserts RTS_B if the number of characters in the receiver data register is full or a start bit is detected that will cause the receiver data register to be full.
• The receiver asserts RTS_B when the number of characters in the receiver data register is not full and has not detected a start bit that will cause the receiver data register to be full. It is not affected if STAT[RDRF] is asserted.
• Even if RTS_B is deasserted, the receiver continues to receive characters until the receiver data buffer is overrun.
• If the receiver request-to-send functionality is disabled, the receiver RTS_B remains deasserted.

### 49.3.4.4 Infrared decoder

The infrared decoder converts the received character from the IrDA format to the NRZ format used by the receiver. It also has a OSR oversampling baud rate clock counter that filters noise and indicates when a 1 is received.

#### 49.3.4.4.1 Start bit detection

When STAT[RXINV] is cleared, the first falling edge of the received character corresponds to the start bit. The infrared decoder resets its counter. At this time, the receiver also begins its start bit detection process. After the start bit is detected, the receiver synchronizes its bit times to this start bit time. For the rest of the character reception, the infrared decoder's counter and the receiver's bit time counter count independently from each other.

#### 49.3.4.4.2 Noise filtering

Any further rising edges detected during the first half of the infrared decoder counter are ignored by the decoder. Any pulses less than one oversampling baud clock can be undetected by it regardless of whether it is seen in the first or second half of the count.

#### 49.3.4.4.3 Low-bit detection

During the second half of the decoder count, a rising edge is decoded as a 0, which is sent to the receiver. The decoder counter is also reset.

#### 49.3.4.4.4 High-bit detection

At OSR oversampling baud rate clocks after the previous rising edge, if a rising edge is not seen, then the decoder sends a 1 to the receiver.

If the next bit is a 0, which arrives late, then a low-bit is detected according to Low-bit detection. The value sent to the receiver is changed from 1 to a 0. Then, if a noise pulse occurs outside the receiver's bit time sampling period, then the delay of a 0 is not recorded as noise.
49.3.5 Additional LPUART functions

The following sections describe additional LPUART functions.

49.3.5.1 Data Modes

The LPUART transmitter and receiver can be configured to operate in 7-bit data mode by setting CTRL[M7], 9-bit data mode by setting the CTRL[M] or 10-bit data mode by setting BAUD[M10]. In 9-bit mode, there is a ninth data bit and in 10-bit mode, there is a tenth data bit. For the transmit data buffer, these bits are stored in CTRL[T8] and CTRL[T9]. For the receiver, these bits are held in CTRL[R8] and CTRL[R9]. They are also accessible via 16-bit or 32-bit accesses to the DATA register.

For coherent 8-bit writes to the transmit data buffer, write to CTRL[T8] and CTRL[T9] before writing to DATA[7:0]. For 16-bit and 32-bit writes to the DATA register, all 10 transmit bits are written to the transmit data buffer at the same time.

If the bit values to be transmitted as the ninth and tenth bit of a new character are the same as for the previous character, it is not necessary to write to CTRL[T8] and CTRL[T9] again. When data is transferred from the transmit data buffer to the transmit shifter, the value in CTRL[T8] and CTRL[T9] is copied at the same time data is transferred from DATA[7:0] to the shifter.

The 9-bit data mode is typically used with parity to allow eight bits of data plus the parity in the ninth bit, or it is used with address-mark wakeup so the ninth data bit can serve as the wakeup bit. The 10-bit data mode is typically used with parity and address-mark wakeup so the ninth data bit can serve as the wakeup bit and the tenth bit as the parity bit. In custom protocols, the ninth and/or tenth bits can also serve as software-controlled markers.

49.3.5.2 Idle length

An idle character is a character where the start bit, all data bits and stop bits are in the mark position. The CTRL[ILT] bit can be configured to start detecting an idle character from the previous start bit (any data bits and stop bits count towards the idle character detection) or from the previous stop bit.
The number of idle characters that must be received before an idle line condition is detected can also be configured using the CTRL[IDLECFG] field. This field configures the number of idle characters that must be received before the STAT[IDLE] flag is set, the STAT[RAF] flag is cleared and the DATA[IDLINE] flag is set with the next received character.

Idle-line wakeup and idle match operation are also affected by the CTRL[IDLECFG] field. When address match or match on/off operation is enabled, setting the STAT[RWUID] bit will cause any discarded characters to be treated as if they were idle characters.

### 49.3.5.3 Loop mode

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Loop mode is sometimes used to check software, independent of connections in the external system, to help isolate system problems. In this mode, the transmitter output is internally connected to the receiver input and the RXD pin is not used by the LPUART.

### 49.3.5.4 Single-wire operation

When CTRL[LOOPS] is set, the CTRL[RSRC] bit chooses between loop mode (CTRL[RSRC] = 0) or single-wire mode (CTRL[RSRC] = 1). Single-wire mode implements a half-duplex serial connection. The receiver is internally connected to the transmitter output and to the TXD pin (the RXD pin is not used).

In single-wire mode, the CTRL[TXDIR] bit controls the direction of serial data on the TXD pin. When CTRL[TXDIR] is cleared, the TXD pin is an input to the receiver and the transmitter is temporarily disconnected from the TXD pin so an external device can send serial data to the receiver. When CTRL[TXDIR] is set, the TXD pin is an output driven by the transmitter, the internal loop back connection is disabled, and as a result the receiver cannot receive characters that are sent out by the transmitter.

### 49.3.6 Infrared interface

The LPUART provides the capability of transmitting narrow pulses to an IR LED and receiving narrow pulses and transforming them to serial bits, which are sent to the LPUART. The IrDA physical layer specification defines a half-duplex infrared communication link for exchanging data. The full standard includes data rates up to 16 Mbits/s. This module covers data rates only between 2.4 kbits/s and 115.2 kbits/s.
The LPUART has an infrared transmit encoder and receive decoder. The LPUART transmits serial bits of data that are encoded by the infrared submodule to transmit a narrow pulse for every zero bit. No pulse is transmitted for every one bit. When receiving data, the IR pulses are detected using an IR photo diode and transformed to CMOS levels by the IR receive decoder, external from the LPUART. The narrow pulses are then stretched by the infrared receive decoder to get back to a serial bit stream to be received by the LPUART. The polarity of transmitted pulses and expected receive pulses can be inverted so that a direct connection can be made to external IrDA transceiver modules that use active high pulses.

The infrared submodule receives its clock sources from the LPUART. One of these two clocks are selected in the infrared submodule to generate either 1/OSR, 2/OSR, 3/OSR, or 4/OSR narrow pulses during transmission.

### 49.3.6.1 Infrared transmit encoder

The infrared transmit encoder converts serial bits of data from transmit shift register to the TXD signal. A narrow pulse is transmitted for a 0 bit and no pulse for a 1 bit. The narrow pulse is sent at the start of the bit with a duration of 1/OSR, 2/OSR, 3/OSR, or 4/OSR of a bit time. A narrow low pulse is transmitted for a 0 bit when CTRL[TXINV] is cleared, while a narrow high pulse is transmitted for a 0 bit when CTRL[TXINV] is set.

### 49.3.6.2 Infrared receive decoder

The infrared receive block converts data from the RXD signal to the receive shift register. A narrow pulse is expected for each 0 received and no pulse is expected for each 1 received. A narrow low pulse is expected for a 0 bit when STAT[RXINV] is cleared, while a narrow high pulse is expected for a 0 bit when STAT[RXINV] is set. This receive decoder meets the edge jitter requirement as defined by the IrDA serial infrared physical layer specification.

### 49.3.7 Interrupts and status flags

The LPUART transmitter has two status flags that can optionally generate hardware interrupt requests. Transmit data register empty STAT[TDRE]) indicates when there is room in the transmit data buffer to write another transmit character to the DATA register. If the transmit interrupt enable CTRL[TIE]) bit is set, a hardware interrupt is requested when STAT[TDRE] is set. Transmit complete (STAT[TC]) indicates that the transmitter is finished transmitting all data, preamble, and break characters and is idle with TXD at
the inactive level. This flag is often used in systems with modems to determine when it is safe to turn off the modem. If the transmit complete interrupt enable (CTRL[TCIE]) bit is set, a hardware interrupt is requested when STAT[TC] is set. Instead of hardware interrupts, software polling may be used to monitor the STAT[TDRE] and STAT[TC] status flags if the corresponding CTRL[TIE] or CTRL[TCIE] local interrupt masks are cleared.

When a program detects that the receive data register is full (STAT[RDRF] = 1), it gets the data from the receive data register by reading the DATA register. The STAT[RDRF] flag is cleared by reading the DATA register.

The IDLE status flag includes logic that prevents it from getting set repeatedly when the RXD line remains idle for an extended period of time. IDLE is cleared by writing 1 to the STAT[IDLE] flag. After STAT[IDLE] has been cleared, it cannot become set again until the receiver has received at least one new character and has set STAT[RDRF].

If the associated error was detected in the received character that caused STAT[RDRF] to be set, the error flags - noise flag (STAT[NF]), framing error (STAT[FE]), and parity error flag (STAT[PF]) - are set at the same time as STAT[RDRF]. These flags are not set in overrun cases.

If STAT[RDRF] was already set when a new character is ready to be transferred from the receive shifter to the receive data buffer, the overrun (STAT[OR]) flag is set instead of the data along with any associated NF, FE, or PF condition is lost.

If the received character matches the contents of MATCH[MA1] and/or MATCH[MA2] then the STAT[MA1F] and/or STAT[MA2F] flags are set at the same time that STAT[RDRF] is set.

At any time, an active edge on the RXD serial data input pin causes the STAT[RXEDGIF] flag to set. The STAT[RXEDGIF] flag is cleared by writing a 1 to it. This function depends on the receiver being enabled (CTRL[RE] = 1).

### 49.3.8 Peripheral Triggers

The connection of the LPUART peripheral triggers with other peripherals are device specific.

#### 49.3.8.1 Output Triggers

The LPUART generates three output triggers that can be connected to other peripherals on the device.
• The transmit word trigger asserts at the end of each transmitted word, it negates after one bit period.
• The receive word trigger asserts at the end of each received word that is written to the receive FIFO, for one oversampling clock period.
• The receive idle trigger asserts at when the idle flag would set, for one oversampling clock period.

### 49.3.8.2 Input Trigger

The LPUART supports one peripheral input trigger, that can be configured in one of the following ways.

• The input trigger can be connected in place of the CTS_B pin input. The input trigger must assert for longer than one bit clock period when the transmitter is idle with data to send to guarantee a new transmission.
• The input trigger can modulate the transmit data output (trigger is logically ANDed with the TXD output). The input trigger is expected to be generated from a PWM source with a period that is less than the bit clock frequency.
• The input trigger can be connected in place of the RXD pin input. The input trigger is expected to be generated from a receive data source, such as analog comparator or external pin.

### 49.4 Register definition

The LPUART includes registers to control baud rate, select options, report status, and store transmit/receive data. Access to an address outside the valid memory map will generate a bus error.

**NOTE**

Writing a Read-Only (RO) register or reading a Write-Only (WO) register can cause bus errors. This module will not check if programmed values in the registers are correct; the application software must ensure that valid programmed values are being written.

### 49.4.1 LPUART register descriptions
49.4.1.1 LPUART Memory map

LPUART\textsubscript{n} base address: 4018\_4000h + (n-1)\times4000h, where n is from 1 to 8.

### 49.4.1.7.3 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 31    | LIN Break Detect Interrupt Flag | LBKDIF is set when the LIN break detect circuitry is enabled and a LIN break character is detected. LBKDIF is cleared by writing a 1 to it.  
0b - No LIN break character has been detected.  
1b - LIN break character has been detected. |
| 30    | RXD Pin Active Edge Interrupt Flag | RXEDGIF is set whenever the receiver is enabled and an active edge, falling if RXINV = 0, rising if RXINV=1, on the RXD pin occurs. RXEDGIF is cleared by writing a 1 to it.  
0b - No active edge on the receive pin has occurred.  
1b - An active edge on the receive pin has occurred. |
| 29    | MSB First | Setting this bit reverses the order of the bits that are transmitted and received on the wire. This bit does not affect the polarity of the bits, the location of the parity bit or the location of the start or stop bits. This bit should only be changed when the transmitter and receiver are both disabled.  
0b - LSB (bit0) is the first bit that is transmitted following the start bit. Further, the first bit received after the start bit is identified as bit0.  
1b - MSB (bit9, bit8, bit7 or bit6) is the first bit that is transmitted following the start bit depending on the setting of CTRL[M], CTRL[PE] and BAUD[M10]. Further, the first bit received after the start bit is identified as bit9, bit8, bit7 or bit6 depending on the setting of CTRL[M] and CTRL[PE]. |
| 28    | Receive Data Inversion | Setting this bit reverses the polarity of the received data input. This bit should only be changed when the receiver is disabled.  
**NOTE:** Setting RXINV inverts the RXD input for all cases: data bits, start and stop bits, break, and idle.  
0b - Receive data not inverted.  
1b - Receive data inverted. |
| 27    | Receive Wake Up Idle Detect | |

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| RWUID | For RWU on idle character, RWUID controls whether the idle character that wakes up the receiver sets the IDLE bit. For address match wakeup, RWUID controls if the IDLE bit is set when the address does not match. This bit should only be changed when the receiver is disabled.  
0b - During receive standby state (RWU = 1), the IDLE bit does not get set upon detection of an idle character. During address match wakeup, the IDLE bit does not set when an address does not match.  
1b - During receive standby state (RWU = 1), the IDLE bit gets set upon detection of an idle character. During address match wakeup, the IDLE bit does set when an address does not match. |

| 26 | Break Character Generation Length |
| BRK13 | BRK13 selects a longer transmitted break character length. Detection of a framing error is not affected by the state of this bit. This bit can be set by writing the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.  
0b - Break character is transmitted with length of 9 to 13 bit times.  
1b - Break character is transmitted with length of 12 to 15 bit times. |

| 25 | LIN Break Detection Enable |
| LBKDE | LBKDE selects a longer break character detection length. While LBKDE is set, receive data is not stored in the receive data buffer.  
0b - LIN break detect is disabled, normal break character can be detected.  
1b - LIN break detect is enabled. LIN break character is detected at length of 11 bit times (if M = 0) or 12 (if M = 1) or 13 (M10 = 1). |

| 24 | Receiver Active Flag |
| RAF | RAF is set when the receiver detects the beginning of a valid start bit, and RAF is cleared automatically when the receiver detects an idle line.  
0b - LPUART receiver idle waiting for a start bit.  
1b - LPUART receiver active (RXD input not idle). |

| 23 | Transmit Data Register Empty Flag |
| TDRE | When the transmit FIFO is enabled, TDRE will set when the number of datawords in the transmit FIFO (DATA register) is equal to or less than the number indicated by WATER[TXWATER]). To clear TDRE, write to the DATA register until the number of words in the transmit FIFO is greater than the number indicated by WATER[TXWATER]. When the transmit FIFO is disabled, TDRE will set when the transmit DATA register is empty. To clear TDRE, write to the DATA register.  
TDRE is not affected by a character that is in the process of being transmitted; it is updated at the start of each transmitted character.  
0b - Transmit data buffer full.  
1b - Transmit data buffer empty. |

| 22 | Transmission Complete Flag |
| TC | TC is cleared when there is a transmission in progress or when a preamble or break character is loaded. TC is set when the transmit buffer is empty and no data, preamble, or break character is being transmitted. When TC is set, the transmit data output signal becomes idle (logic 1). TC is cleared by writing to the DATA register to transmit new data, queuing a preamble by clearing and then setting CTRL[TE], queuing a break character by writing 1 to CTRL[SBK].  
0b - Transmitter active (sending data, a preamble, or a break).  
1b - Transmitter idle (transmission activity complete). |

| 21 | Receive Data Register Full Flag |
| RDRF | When the receive FIFO is enabled, RDRF is set when the number of datawords in the receive buffer is greater than the number indicated by WATER[RXWATER]. To clear RDRF, read the DATA register until the number of datawords in the receive data buffer is equal to or less than the number indicated by WATER[RXWATER]. When the receive FIFO is disabled, RDRF is set when the receive buffer (the DATA register) is full. To clear RDRF, read the DATA register.  
Table continues on the next page...
A character that is in the process of being received does not cause a change in RDRF until the entire character is received. Even if RDRF is set, the character will continue to be received until an overrun condition occurs once the entire character is received.

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b</td>
<td>Receive data buffer empty.</td>
</tr>
<tr>
<td>1b</td>
<td>Receive data buffer full.</td>
</tr>
</tbody>
</table>

**IDLE**

IDLE is set when the LPUART receive line becomes idle for a full character time after a period of activity. When CTRL[ILT] is cleared, the receiver starts counting idle bit times after the start bit. If the receive character is all 1s, these bit times and the stop bits time count toward the full character time of logic high, 10 to 13 bit times, needed for the receiver to detect an idle line. When CTRL[ILT] is set, the receiver doesn't start counting idle bit times until after the stop bits. The stop bits and any logic high bit times at the end of the previous character do not count toward the full character time of logic high needed for the receiver to detect an idle line.

To clear IDLE, write logic 1 to the IDLE flag. After IDLE has been cleared, it cannot be set again until after a new character has been stored in the receive buffer or a LIN break character has set the LBKDIF flag. IDLE is set only once even if the receive line remains idle for an extended period.

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b</td>
<td>No idle line detected.</td>
</tr>
<tr>
<td>1b</td>
<td>Idle line was detected.</td>
</tr>
</tbody>
</table>

**OR**

OR is set when software fails to prevent the receive data register from overflowing with data. The OR bit is set immediately after the stop bit has been completely received for the dataword that overflows the buffer and all the other error flags (FE, NF, and PF) are prevented from setting. The data in the shift register is lost, but the data already in the LPUART data registers is not affected. If LBKDE is enabled and a LIN Break is detected, the OR field asserts if LBKDIF is not cleared before the next data character is received.

While the OR flag is set, no additional data is stored in the data buffer even if sufficient room exists. To clear OR, write logic 1 to the OR flag.

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b</td>
<td>No overrun.</td>
</tr>
<tr>
<td>1b</td>
<td>Receive overrun (new LPUART data lost).</td>
</tr>
</tbody>
</table>

**NF**

The advanced sampling technique used in the receiver takes three samples in each of the received bits. If any of these samples disagrees with the rest of the samples within any bit time in the frame then noise is detected for that character. NF is set whenever the next character to be read from the DATA register was received with noise detected within the character. To clear NF, write logic 1 to the NF field.

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b</td>
<td>No noise detected.</td>
</tr>
<tr>
<td>1b</td>
<td>Noise detected in the received character in the DATA register.</td>
</tr>
</tbody>
</table>

**FE**

FE is set whenever the next character to be read from the DATA register was received with logic 0 detected where a stop bit was expected. To clear FE, write logic 1 to the FE field.

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b</td>
<td>No framing error detected. This does not guarantee the framing is correct.</td>
</tr>
<tr>
<td>1b</td>
<td>Framing error.</td>
</tr>
</tbody>
</table>

**PF**

PF is set whenever the next character to be read from the DATA register was received when parity is enabled (PE = 1) and the parity bit in the received character does not agree with the expected parity value. To clear PF, write a logic 1 to the PF field.

<table>
<thead>
<tr>

<tr>
<td>25</td>
<td>Framing Error Interrupt Enable</td>
</tr>
<tr>
<td>FEIE</td>
<td>This bit enables the framing error flag (FE) to generate hardware interrupt requests. 0b - FE interrupts disabled; use polling. 1b - Hardware interrupt requested when FE is set.</td>
</tr>
<tr>
<td>24</td>
<td>Parity Error Interrupt Enable</td>
</tr>
<tr>
<td>PEIE</td>
<td>This bit enables the parity error flag (PF) to generate hardware interrupt requests. 0b - PF interrupts disabled; use polling. 1b - Hardware interrupt requested when PF is set.</td>
</tr>
<tr>
<td>23</td>
<td>Transmit Interrupt Enable</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
### Field | Function
--- | ---
TIE | Enables STAT[TDRE] to generate interrupt requests.  
   0b - Hardware interrupts from TDRE disabled; use polling.  
   1b - Hardware interrupt requested when TDRE flag is 1.  

| 22 | Transmission Complete Interrupt Enable for  
TCIE | TCIE enables the transmission complete flag, TC, to generate interrupt requests.  
   0b - Hardware interrupts from TC disabled; use polling.  
   1b - Hardware interrupt requested when TC flag is 1.  

| 21 | Receiver Interrupt Enable  
RIE | Enables STAT[RDRF] to generate interrupt requests.  
   0b - Hardware interrupts from RDRF disabled; use polling.  
   1b - Hardware interrupt requested when RDRF flag is 1.  

| 20 | Idle Line Interrupt Enable  
ILIE | ILIE enables the idle line flag, STAT[IDLE], to generate interrupt requests.  
   0b - Hardware interrupts from IDLE disabled; use polling.  
   1b - Hardware interrupt requested when IDLE flag is 1.  

| 19 | Transmitter Enable  
TE | Enables the LPUART transmitter. TE can also be used to queue an idle preamble by clearing and then setting TE. When TE is cleared, this register bit will read as 1 until the transmitter has completed the current character and the TXD pin is tristated.  
   A single idle character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] set.  
   0b - Transmitter disabled.  
   1b - Transmitter enabled.  

| 18 | Receiver Enable  
RE | Enables the LPUART receiver. When RE is written to 0, this register bit will read as 1 until the receiver finishes receiving the current character (if any).  
   0b - Receiver disabled.  
   1b - Receiver enabled.  

| 17 | Receiver Wakeup Control  
RWU | This field can be set to place the LPUART receiver in a standby state. RWU automatically clears when an RWU event occurs, that is, an IDLE event when CTRL[WAKE] is clear or an address match when CTRL[WAKE] is set with STAT[RWUID] is clear.  
   **NOTE:** RWU must be set only with CTRL[WAKE] = 0 (wakeup on idle) if the channel is currently not idle. This can be determined by STAT[RAF]. If the flag is set to wake up an IDLE event and the channel is already idle, it is possible that the LPUART will discard data. This is because the data must be received or a LIN break detected after an IDLE is detected before IDLE is allowed to be reasserted.  
   0b - Normal receiver operation.  
   1b - LPUART receiver in standby waiting for wakeup condition.  

| 16 | Send Break  
SBK | Writing a 1 and then a 0 to SBK queues a break character in the transmit data stream. Additional break characters of 9 to 13 bits, or 12 to 15 bits if STAT[BRK13] is set, bit times of logic 0 are queued as long as SBK is set. Depending on the timing of the set and clear of SBK relative to the character currently being transmitted, a second break character may be queued before software clears SBK.  
   A single break character can also be queued by writing to the transmit FIFO with DATA[FRETSC] set and DATA[R9T9] clear.  
   0b - Normal transmitter operation.  
   1b - Queue break character(s) to be sent.  

*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 15 MA1IE | Match 1 Interrupt Enable  
0b - MA1F interrupt disabled  
1b - MA1F interrupt enabled |
| 14 MA2IE | Match 2 Interrupt Enable  
0b - MA2F interrupt disabled  
1b - MA2F interrupt enabled |
| 13-12 | Reserved |
| 11 M7 | 7-Bit Mode Select  
This bit should only be changed when the transmitter and receiver are both disabled.  
0b - Receiver and transmitter use 8-bit to 10-bit data characters.  
1b - Receiver and transmitter use 7-bit data characters. |
| 10-8 IDLECFG | Idle Configuration  
Configures the number of idle characters that must be received before the IDLE flag is set.  
000b - 1 idle character  
001b - 2 idle characters  
010b - 4 idle characters  
011b - 8 idle characters  
100b - 16 idle characters  
101b - 32 idle characters  
110b - 64 idle characters  
111b - 128 idle characters |
| 7 LOOPS | Loop Mode Select  
When LOOPS is set, the RXD pin is disconnected from the LPUART and the transmitter output is internally connected to the receiver input. The transmitter and the receiver must be enabled to use the loop function.  
0b - Normal operation - RXD and TXD use separate pins.  
1b - Loop mode or single-wire mode where transmitter outputs are internally connected to receiver input (see RSRC bit). |
| 6 DOZEEN | Doze Enable  
0b - LPUART is enabled in Doze mode.  
1b - LPUART is disabled in Doze mode. |
| 5 RSRC | Receiver Source Select  
This field has no meaning or effect unless the LOOPS field is set. When LOOPS is set, the RSRC field determines the source for the receiver shift register input.  
0b - Provided LOOPS is set, RSRC is cleared, selects internal loop back mode and the LPUART does not use the RXD pin.  
1b - Single-wire LPUART mode where the TXD pin is connected to the transmitter output and receiver input. |
| 4 M | 9-Bit or 8-Bit Mode Select  
0b - Receiver and transmitter use 8-bit data characters.  
1b - Receiver and transmitter use 9-bit data characters. |
| 3 WAKE | Receiver Wakeup Method Select  
Determines which condition wakes the LPUART when RWU=1:  
- Address mark in the bit preceding the stop bit (or bit preceding the parity bit when parity is enabled) of the received data character, or  
- An idle condition on the receive pin input signal.  
0b - Configures RWU for idle-line wakeup.  
1b - Configures RWU with address-mark wakeup. |

### Register definition

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>This field should only be changed when the receiver is disabled.</strong></td>
<td></td>
</tr>
<tr>
<td><strong>7-6</strong></td>
<td>Reserved</td>
</tr>
</tbody>
</table>
| **5**   | TXCTSSRC  
  **Transmit CTS Source**  
  Configures the source of the CTS input.  
  0b - CTS input is the CTS_B pin.  
  1b - CTS input is the inverted Receiver Match result. |
| **4**   | TXCTSC  
  **Transmit CTS Configuration**  
  Configures if the CTS state is checked at the start of each character or only when the transmitter is idle.  
  0b - CTS input is sampled at the start of each character.  
  1b - CTS input is sampled when the transmitter is idle. |
| **3**   | RXRTSE  
  **Receiver request-to-send enable**  
  Allows the RTS output to control the CTS input of the transmitting device to prevent receiver overrun.  
  This bit should only be changed when the receiver is disabled.  
  **NOTE:** Do not set both RXRTSE and TXRTSE.  
  0b - The receiver has no effect on RTS.  
  1b - RTS is deasserted if the receiver data register is full or a start bit has been detected that would cause the receiver data register to become full. RTS is asserted if the receiver data register is not full and has not detected a start bit that would cause the receiver data register to become full. |
| **2**   | TXRTSPOL  
  **Transmitter request-to-send polarity**  
  Controls the polarity of the transmitter RTS. TXRTSPOL does not affect the polarity of the receiver RTS. RTS will remain negated in the active low state unless TXRTSE is set. This bit should only be changed when the transmitter is disabled.  
  0b - Transmitter RTS is active low.  
  1b - Transmitter RTS is active high. |
| **1**   | TXRTSE  
  **Transmitter request-to-send enable**  
  Controls RTS before and after a transmission. This bit should only be changed when the transmitter is disabled.  
  0b - The transmitter has no effect on RTS.  
  1b - When a character is placed into an empty transmitter data buffer, RTS asserts one bit time before the start bit is transmitted. RTS deasserts one bit time after all characters in the transmitter data buffer and shift register are completely sent, including the last stop bit. |
| **0**   | TXCTSE  
  **Transmitter clear-to-send enable**  
  TXCTSE controls the operation of the transmitter. TXCTSE can be set independently from the state of TXRTSE and RXRTSE.  
  0b - CTS has no effect on the transmitter.  
  1b - Enables clear-to-send operation. The transmitter checks the state of CTS each time it is ready to send a character. If CTS is asserted, the character is sent. If CTS is deasserted, the signal TXD remains in the mark state and transmission is delayed until CTS is asserted. Changes in CTS as a character is being sent do not affect its transmission. |

### 49.4.1.12 LPUART FIFO Register (FIFO)
49.4.1.12.1 Offset

**NOTE**

In this device, FLEXIO1 and FLEXIO2/3 parameters are not exactly the same. FLEXIO1 has 16 pins, while FLEXIO2/3 has 32 pins.

**NOTE**

FlexIO cannot shift and store on the same cycle. For example, when trying to use FlexIO emulate the SSI slave device, will find it fail to shift and store on the same cycle, and the last falling edge of the clock is not used to latch the last data bit. One workaround is to use other timer count the number bit periods and generate the disable signals. However, it has two limitations: 1) it needs to know the transmitting rate, and set this timer with the same baud rate. 2) it requires the transmitting is asynchronous, does not have any clock stretch; otherwise, it will result in fail. So the slave receiving is not synchronous.
50.2 Introduction

50.2.1 Overview
The FlexIO is a highly configurable module providing a wide range of functionality including:
- Emulation of a variety of serial/parallel communication protocols
- Flexible 16-bit timers with support for a variety of trigger, reset, enable and disable conditions
- Programmable logic blocks allowing the implementation of digital logic functions on-chip and configurable interaction of internal and external modules
- Programmable state machine for offloading basic system control functions from CPU

50.2.2 Features
The FlexIO module is capable of supporting a wide range of protocols including, but not limited to:
- UART
- I2C
- SPI
- I2S
- Camera IF
- Motorola 68K/Intel 8080 bus
- PWM/Waveform generation

The following key features are provided:
- Array of 32-bit shift registers with transmit, receive and data match modes
- Double buffered shifter operation for continuous data transfer
- Shifter concatenation to support large transfer sizes
- Automatic start/stop bit generation
- 1, 2, 4, 8, 16 or 32 multi-bit shift widths for parallel interface support
- Interrupt, DMA or polled transmit/receive operation
- Programmable baud rates independent of bus clock frequency, with support for asynchronous operation during stop modes
- Highly flexible 16-bit timers with support for a variety of internal or external trigger, reset, enable and disable conditions
• Programmable logic mode for integrating external digital logic functions on-chip or combining pin/shifter/timer functions to generate complex outputs
• Programmable state machine for offloading basic system control functions from CPU with support for up to 8 states, 8 outputs and 3 selectable inputs per state

50.2.3 Block Diagram

The following diagram gives a high-level overview of the configuration of FlexIO timers and shifters.

![FlexIO block diagram](image)

50.3 Functional description

50.3.1 Clocking and Resets

50.3.1.1 Functional clock

The FlexIO functional clock is asynchronous to the bus clock and can remain enabled in low power modes. The FlexIO functional clock must be enabled before accessing any FlexIO registers.

50.3.1.2 Bus clock

The bus clock is only used for bus accesses to the control and configuration registers.

50.3.1.3 Chip reset

The logic and registers for the FlexIO are reset to their default state on a chip reset.
50.3.1.4 Software reset

The FlexIO implements a software reset bit in its Control Register. The CTRL[RST] will reset all logic and registers to their default state, except for the CTRL itself.

50.3.2 Shifter operation

Shifters are responsible for buffering and shifting data into or out of the FlexIO. The timing of shift, load and store events are controlled by the Timer assigned to the Shifter via the SHIFTCTL[TIMSEL] register. The Shifters are designed to support either DMA, interrupt or polled operation. The following block diagram provides a detailed view of the Shifter microarchitecture.

![Shifter Microarchitecture](image)

**Figure 50-2. Shifter Microarchitecture**

50.3.2.1 Transmit Mode

When configured for Transmit mode (SHIFTCTL[SMOD]=Transmit), the shifter will load data from the SHIFTBUF register and shift data out when a load event is signalled by the assigned Timer. An optional start/stop bit can also be automatically loaded before/after SHIFTBUF data by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Note that the shifter will immediately load a stop bit when the Shifter is initially configured for Transmit mode if a stop bit is enabled.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been loaded from the SHIFTBUF register into the Shifter or when the Shifter is initially configured into Transmit mode. The flag will clear when new data has been written into the SHIFTBUF register.
The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when an attempt to load data from an empty SHIFTBUF register occurs (buffer underrun). The flag can be cleared by writing it with logic 1.

50.3.2.2 Receive Mode

When configured for Receive mode (SHIFTCTL[SMOD]=Receive), the shifter will shift data in and store data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when an attempt to store data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.

50.3.2.3 Match Store Mode

When configured for Match Store mode (SHIFTCTL[SMOD]=Match Store), the shifter will shift data in, check for a match result and store matched data into the SHIFTBUF register when a store event is signalled by the assigned Timer. Checking for a start/stop bit can be enabled before/after shifter data is sampled by configuring the SHIFTCFG[SSTART], TIMCFG[TSTART] or SHIFTCFG[SSTOP], TIMCFG[TSTOP] registers in the Shifter and Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs and matched data has been stored into the SHIFTBUF register from the Shifter. The flag will clear when the matched data has been read from the SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when an attempt to store matched data into a full SHIFTBUF register occurs (buffer overrun) or when a mismatch occurs on a start/stop bit check. The flag can be cleared by writing it with logic 1.
50.3.2.4 Match Continuous Mode

When configured for Match Continuous mode (SHIFTCTL[SMOD]=Match Continuous), the shifter will shift data in and continuously check for a match result whenever a shift event is signalled by the assigned Timer. Up to 16-bits of data can be compared using SHIFTBUF[31:16] to configure the data to be matched and SHIFTBUF[15:0] to mask the match result.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set when a match occurs. The flag will clear automatically as soon as there is no longer a match between Shifter data and SHIFTBUF register.

The Shifter Error Flag (SHIFTERR[SEF]) and any enabled interrupts will set when a match occurs. The flag will clear when there is a read from the SHIFTBUF register or it written with logic 1.

50.3.2.5 State Mode

Using State mode enables the user to implement any state machine with up to 8 states, 8 outputs and 3 selectable inputs per state. This feature allows basic control functions to be offloaded from the CPU, which could potentially remain in a STOP/VLPS low power mode.

When configured for State mode (SHIFTCTL[SMOD]=State), the SHIFTBUF register is used to drive the output and compute next state values when the Shifter has been selected by the current state pointer (SHIFTSTATE[STATE]). The following diagram provides a detailed view of Shifter microarchitecture when configured for State mode.

Figure 50-3. State Microarchitecture
When Shifter i has been selected by the current state pointer, output pins FXIO_D[7:0] will be driven by SHIFTBUF[i][31:24] using the configuration set by SHIFTCTL[i][PINCFG]. When set, SHIFTCFG[i]{PINW[3:0],STOP[1:0],START[1:0]} are respectively used to disable the output drive on pins FXIO_D[7:0] for state machine applications which require less than 8 output pins.

The next state value is computed using the 3 input pins selected by SHIFTCTL[i][PINSEL] together with SHIFTBUF[i][23:0]. Note that each state could potentially use a different set of 3 input pins. The following table details how the next state value is computed when the current state pointer is pointing to Shifter i.

**Table 50-3. Next State computation for SHIFTSTATE[STATE]=i**

</tr>
</tbody>
</table>

Note that other shifters/timers could potentially be configured to drive the input pins of a given state, allowing the user to create complex combinations of shifters/timers as desired e.g. the output of a Shifter configured for logic mode could potentially be used to drive a state machine input.

The next state transition is triggered using the Timer output selected by SHIFTCTL[i][TIMSEL] with polarity controlled by SHIFTCTL[i][TIMPOL]. Note that each state could potentially use a different Timer to trigger each next state transition, allowing a variety of internal/external trigger sources and clocking configurations to be used (see Timer section for more detail).

The current state pointer defaults to Shifter 0 at reset, however it can be written by the user to select a different Shifter for the initial state. If the current state pointer selects a Shifter which is not configured for State mode, then outputs will not be driven and a next state transition is never triggered.

The Shifter Status Flag (SHIFTSTAT[SSF]) and any enabled interrupts or DMA requests will set whenever the Shifter has been selected by the current state pointer. The flag will clear when the current state pointer is updated to a different Shifter.
50.3.2.6 Logic Mode

Using logic mode enables the user to implement a small amount of programmable digital logic within a FlexIO Shifter. This feature allows board-level glue logic to be integrated on-chip using FlexIO hardware.

When configured for Logic mode (SHIFTCTL[SMOD]=Logic), the SHIFTBUF register is used to implement a 5-input, 32-bit programmable logic look-up table. The following diagram provides a detailed view of Shifter microarchitecture when configured for Logic mode.

![Logic Microarchitecture Diagram](image)

The look-up table is driven using 4 pin inputs (maskable using SHIFTCFG[SSTOP] and SHFITCFG[SSTART]) plus 1 input from the internal shifter and can be configured to drive an output pin using the SHIFTCTL[PINCFG] field. Pin inputs and outputs are fixed for each logic look-up table and are not selectable. The following table lists the logic output value selected by the look-up table for Shifter 'i'.

1. for Shifter i=0...3, x=i
To minimize output glitches, \texttt{SHIFTCFG[SSTOP]} and \texttt{SHIFTCFG[SSTART]} can be used to mask unused input pins. When set, \{\texttt{SSTOP[1:0]}, \texttt{SSTART[1:0]}\} will mask \texttt{FXIO\_D[x+3]...FXIO\_D[x]} inputs respectively, so that any transitions on these pins will not cause the logic output to glitch.

Note that other shifters/timers could potentially be configured to drive the input pins of a given look-up table (without synchronization), allowing the user to concatenate look-up tables or create complex combinations of shifters/timers as desired.

\texttt{SHIFTCFG[PWIDTH]} will control the number of delay stages introduced by the internal shifter input (\texttt{SHIFTERi[0]}). For example, when configured for 1-bit shift (\texttt{PWIDTH}=0), the internal shifter will introduce a 32 Shift clock delay before passing its input (selected by \texttt{SHIFTCtrl[PINSEL]}) to the look-up table. When configured for 32-bit shift (\texttt{PWIDTH}=16...31), the internal shifter will introduce a 1 Shift clock delay to its input.

The Shifter Status Flag (\texttt{SHIFTSTAT[SSF]}) and any enabled interrupts or DMA requests will set whenever the output pin allocated to the logic look-up table has a value of 1 (after being synchronized to the FlexIO clock). The flag will clear when the output pin has a value of 0. This also allows the SSF flag to be used as a trigger to a Timer if desired.

The Shifter Error Flag (\texttt{SHIFTERR[SEF]}) and any enabled interrupts will set when the output pin allocated to the logic look-up table has a value of 1. The flag can be cleared by writing it with logic 1.

### 50.3.3 Timer Operation

The FlexIO 16-bit timers control the loading, shifting and storing of the shift registers, the counters load the contents of the compare register and decrement down to zero on the FlexIO clock. They can perform generic timer functions such as generating a clock or select output or a PWM waveform. Timers can be configured to enable in response to a trigger, pin or shifter condition; decrement always or only on a trigger or pin edge; reset in response to a trigger or pin condition; and disable on a trigger or pin condition or on a timer compare. Timers can optionally include a start condition and/or stop condition.

Each timer operates independently, although a timer can be configured to enable or disable at the same time as the previous timer (eg: timer1 can enable or disable at the same time as timer 0) and a timer output can be used to trigger any other timer. The trigger used by each timer is configured independently and can be configured to be a timer output, shifter status flag, pin input or an external trigger input (refer to the chip
configuration section for details on the external trigger connections). The trigger configuration is separate from the pin configuration, which can be configured for input, output data or output enable.

The Timer Configuration Register (TIMCFGn) should be configured before setting the Timer Mode (TIMOD).

### 50.3.3.1 Timer 8-bit Baud Counter Mode

In 8-bit Baud Counter Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the baud rate of the shift clock and the upper 8-bits are used to configure the number number of shift clock edges in the transfer. When the lower 8-bits decrement to zero, the timer output is toggled and the lower 8-bits reload from the compare register. The upper 8-bits only decrement when the lower 8-bits equal zero and decrement.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

### 50.3.3.2 Timer 8-bit High PWM Mode

In 8-bit High PWM Mode, the 16-bit counter is divided into two 8-bit counters. The lower 8-bits are used to configure the timer output high period and the upper 8-bits are used to configure the timer output low period. The lower 8-bits decrement when the output is high. When the lower 8-bits equal zero and decrement, the timer output is cleared and the lower 8-bits are reloaded from the compare register. The upper 8-bits decrement when the output is low. When the upper 8-bits equal zero and decrement, the timer output is set and the upper 8-bits are reloaded from the compare register.

A timer compare event occurs when the upper 8-bits equal zero and decrements. The timer status flag is set on a timer compare event.

### 50.3.3.3 Timer 16-bit Counter Mode

In 16-bit Counter Mode, the 16-bit counter can be used to configure either the baud rate of the shift clock (eg: TIMDEC[1:0] != 10 or 11) or the number of shift clock edges in the transfer (eg: TIMDEC[1:0] = 10 or 11). When the 16-bit counter equals zero and decrements, the timer output toggles and the counter reloads from the compare register.

A timer compare event occurs when the 16-bit counter equals zero and decrements. The timer status flag is set on a timer compare event.
50.3.3.4 Timer Enable and Start Bit

When the TIMOD is configured for the desired mode, and the condition configured by timer enable (TIMENA) is detected then the following events occur.

- Timer counter will load the current value of the compare Register and start decrementing as configured by TIMDEC.
- Timer output will set depending on the TIMOUT configuration.
- Transmit shifters controlled by this timer will either output their start bit value, or load the shift register from the shift buffer and output the first bit, as configured by SSTART.

If the Timer start bit is enabled, the timer counter will reload with the compare register on the first rising edge of the shift clock after the timer starts decrementing. If there is no falling edge on the shift clock before the first rising edge (for example, when TIMOUT=1), a shifter that is configured to shift on falling edge and load on the first shift will not load correctly.

50.3.3.5 Timer Decrement and Reset

The Timer will then generate the timer output and timer shift clock depending on the TIMOD and TIMDEC fields. The shifter clock is either equal to the timer output (when TIMDEC != 10 or 11) or equal to the decrement clock (when TIMDEC = 10 or 11).

When TIMDEC is configured to decrement from a pin or trigger, the timer will decrement on both rising and falling edges.

When the Timer is configured to reset as configured in the TIMRST field then the Timer counter will load the current value of the compare register again, the timer output may also be affected by the reset as configured in TIMOUT.

In general, when the timer counter decrements to zero a timer compare event is triggered. The timer compare event will cause the timer counter to load the contents of the timer compare register, the timer output to toggle, any configured transmit shift registers to load, and any configured receive shift registers to store. Depending on the mode, the timer status flag may also be set,

50.3.3.6 Timer Disable and Stop Bit

When the is Timer is configured to add a stop bit on each compare, the following additional events will occur.
Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).

Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.

On the first rising edge of the shifter clock after the compare, the timer counter will reload the current value of the Compare Register.

Transmit shifters must be configured to load on the first shift when the timer is configured to insert a stop bit on each compare.

When the condition configured by timer disable (TIMDIS) is detected, the following events occur.

- Timer counter will reload the current value of the Compare Register and start decrementing as configured by TIMDEC.
- Timer output will clear.
- Transmit shifters controlled by this timer will output their stop bit value (if configured by SSTOP).
- Receive shifters controlled by this timer will store the contents of the shift register in their shift buffer, as configured by SSTOP.

If the timer stop bit is enabled, the timer counter will continue decrementing until the next rising edge of the shift clock is detected, at which point it will finish.

A timer enable condition can be detected in the same cycle as a timer disable condition (if timer stop bit is disabled), or on the first rising edge of the shift clock after the disable condition (if stop bit is enabled). Receive shift registers with stop bit enabled will store the contents of the shift register into the shift buffer and verify the state of the input data on the configured shift edge while the timer is in the stop state condition. If there is no configured edge between the timer disable and the next rising edge of the shift clock then the final store and verify do not occur.

### 50.3.4 Pin operation

The pin configuration for each timer and shifter can be configured to use any FlexIO pin with either polarity. Each timer and shifter can be configured as an input, output data, output enable or bidirectional output. A pin configured for output enable can be used as an open drain (with inverted polarity, since the output enable assertion would cause logic zero to be output on the pin) or to control the enable on the bidirectional output. Any timer or shifter could be configured to control the output enable for a pin where the bidirectional output data is driven by another timer or shifter.
50.3.4.1 Parallel Interface
Shifters can be configured to use multiple FlexIO pins in parallel using the
SHIFTCFG[PWIDTH] field. PWIDTH is used to configure the following settings of a
shifter:
1. Number of bits shifted per Shift clock.
2. Number of pins driven by the shifter per Shift clock (only on shifters supporting
   parallel transmit i.e. SHIFTER0, SHIFTER4).
3. Number of pins sampled by the shifter per Shift clock (only on Shifter supporting
   parallel receive i.e. SHIFTER3, SHIFTER7).

When configured for parallel shift, either 4, 8, 16 or 32-bits can be shifted on every Shift
clock. If an adjacent shifter is selected as the input source (SHIFTCFG[INSRC]=1), the
least significant 4, 8, 16 or 32-bits from the adjacent shifter will be sampled on each Shift
clock.

For shifters supporting parallel receive (SHIFTER3, SHIFTER7), the shifter can be
configured to sample multiple pins (SHIFTCFG[INSRC]=0), with PWIDTH and
PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].
Note that if PWIDTH is less than the number of bits being shifted on each Shift clock,
then the most significant bits will be masked with 0 e.g. if PINSEL=7 and PWIDTH=6,
then SHIFTER[31:24] will sample {0,0,FXIO_D[12:7]} on each Shift clock.

For shifters supporting parallel transmit (SHIFTER0, SHIFTER4), the shifter can be
configured to drive multiple pins using SHIFTCTL[PINCFG], with PWIDTH and
PINSEL selecting the pins as follows: FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL].
Note that if PWIDTH is less than the number of bits being shifted on each Shift clock,
then the most significant pins will not be driven e.g. if PINSEL=7 and PWIDTH=6, then
SHIFTER[5:0] will drive only FXIO_D[12:7] on each Shift clock.

50.3.4.2 Pin Synchronization
When configuring a pin as an input (this includes a timer trigger configured as a pin
input), the input signal is first synchronized to the FlexIO clock before the signal is used
by a timer or shifter. This introduces a small latency of between 0.5 to 1.5 FlexIO clock
cycles when using an external pin input to generate an output or control a shifter. This
sets the maximum setup time at 1.5 FlexIO clock cycles.

If an input is used by more than one timer or shifter then the synchronization occurs once
to ensure any edge is seen on the same cycle by all timers and shifters using that input.
Note that FlexIO pins are also connected internally, configuring a FlexIO shifter or timer to output data on an unused pin will make an internal connection that allows other shifters and timer to use this pin as an input. This allows a shifter output to be used to trigger a timer or a timer output to be shifted into a shifter. This path is also synchronized to the FlexIO clock and therefore incurs a 1 cycle latency.

So when using a Pin input as a Timer Trigger, Timer Clock or Shifter Data Input, the following synchronization delays occur:
1. 0.5 – 1.5 FlexIO clock cycles for external pin
2. 1 FlexIO clock cycle for an internally driven pin

For timing considerations such as output valid time and input setup time for specific applications (SPI Master, SPI Slave, I2C Master, I2S Master, I2S Slave) please refer to the FlexIO Application Information Section.

50.3.5 Interrupts and DMA Requests

The following table illustrates the status flags that can generate the FlexIO interrupt and DMA requests.

<td>Y</td>
<td>N</td>
<td>Y</td>
</tr>
</tbody>
</table>

50.3.6 Peripheral Triggers

The connection of the FlexIO peripheral triggers with other peripherals are device specific.

50.3.6.1 Output Triggers

Each FlexIO Timer generates an output trigger equal to the timer output. The output trigger is not affected by the timer pin polarity configuration.
50.3.6.2 Input Trigger

FlexIO supports multiple external trigger inputs that can be used to trigger one or more FlexIO timers. The external triggers are synchronized to the FlexIO functional clock and must assert for at least two cycles of the FlexIO functional clock to be sampled correctly.

50.4 Application Information

This section provides examples for a variety of FlexIO module applications.

50.4.1 UART Transmit

UART transmit can be supported using one Timer, one Shifter and one Pin (two Pins if supporting CTS). The start and stop bit insertion is handled automatically and multiple transfers can be supported using DMA controller. The timer status flag can be used to indicate when the stop bit of each word is transmitted.

Break and idle characters require software intervention, before transmitting a break or idle character the SSTART and SSTOP fields should be altered to transmit the required state and the data to transmit must equal 0xFF or 0x00. Supporting a second stop bit requires the stop bit to be inserted into the data stream using software (and increasing the number of bits to transmit). Note that when performing byte writes to SHIFTBUF$n$ (or SHIFTBUF$F$ for transmitting MSB first), the rest of the register remains unaltered allowing an address mark bit or additional stop bit to remain undisturbed.

FlexIO does not support automatic insertion of parity bits.

</tr>
</tbody>
</table>

### 50.4.2 UART Receive

UART receive can be supported using one Timer, one Shifter and one Pin (two Timers and two Pins if supporting RTS). The start and stop bit verification is handled automatically and multiple transfers can be supported using the DMA controller. The timer status flag can be used to indicate when the stop bit of each word is received.

Triple voting of the received data is not supported by FlexIO, data is sampled only once in the middle of each bit. Another timer can be used to implement a glitch filter on the incoming data, another Timer can also be used to detect an idle line of programmable length. Break characters will cause the error flag to set and the shifter buffer register will return 0x00.

FlexIO does not support automatic verification of parity bits.

</tbody>
</table>

The UART Receiver with RTS configuration uses a 2nd Timer to generate the RTS output. The RTS will assert when the start bit is detected and negate when the data is read from the shifter buffer register. No start bit will be detected while the RTS is asserted, the received data is simply ignored.

#### 50.4.3 SPI Master

SPI master mode can be supported using two Timers, two Shifters and four Pins. Either CPHA=0 or CPHA=1 can be supported and transfers can be supported using the DMA controller. For CPHA=1, the select can remain asserted for multiple transfers and the timer status flag can be used to indicate the end of the transfer.

The stop bit is used to guarantee a minimum of 1 clock cycle between the slave select negating and before the next transfer. Writing to the transmit buffer by either core or DMA is used to initiate each transfer.

Due to synchronization delays, the setup time for the serial input data is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

## 50.4.5 I2C Master

I2C master mode can be supported using two Timers, two Shifters and two Pins. One timer is used to generate the SCL output and one timer is used to control the shifters. The two shifters are used to transmit and receive for every word, when receiving the transmitter must transmit 0xFF to tristate the output. FlexIO inserts a stop bit after every word to generate/verify the ACK/NACK. FlexIO waits for the first write to the transmit data buffer before enabling SCL generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The first timer generates the bit clock for the entire packet (START to Repeated START/STOP), so the compare register needs to be programmed with the total number of clock edges in the packet (minus one). The timer supports clock stretching using the reset counter when pin equal to output (although this increases both the clock high and clock low periods by at least 1 FlexIO clock cycle each). The second timer uses the SCL input pin to control the transmit/receive shift registers, this enforces an SDA data hold time by an extra 2 FlexIO clock cycles.

Both the transmit and receive shifters need to be serviced for each word in the transfer, the transmit shifter must transmit 0xFF when receiving and the receive shifter returns the data actually present on the SDA pin. The transmit shifter will load 1 additional word on the last falling edge of SCL pin, this word should be 0x00 if generating a STOP condition or 0xFF if generating a repeated START condition. During the last word of a master-receiver transfer, the transmit SSTOP bit should be set by software to generate a NACK.

The receive shift register will assert an error interrupt if a NACK is detected, but software is responsible for generating the STOP or repeated START condition. If a NACK is detected during master-transmit, the interrupt routine should immediately write the transmit shifter register with 0x00 (if generating STOP) or 0xFF (if generating repeated START). Software should then wait for the next rising edge on SCL and then disable both timers. The transmit shifter should then be disabled after waiting the setup delay for a repeated START or STOP condition.
Due to synchronization delays, the data valid time for the transmit output is 2 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The I2C master data valid is delayed 2 cycles because the clock output is passed through a synchronizer before clocking the transmit/receive shifter (to guarantee some SDA hold time). Since the SCL output is synchronous with FlexIO clock, the synchronization delay is 1 cycle and then 1 cycle to generate the output.

50.4.6 I2S Master

I2S master mode can be supported using two Timers, two Shifters and four Pins. One timer is used to generate the bit clock and control the shifters and one timer is used to generate the frame sync. FlexIO waits for the first write to the transmit data buffer before enabling bit clock and frame sync generation. Data transfers can be supported using the DMA controller and the shifter error flag will set on transmit underrun or receive overflow.

The bit clock frequency is an even integer divide of the FlexIO clock frequency, and the initial frame sync assertion occurs at the same time as the first bit clock edge. The timer uses the start bit to ensure the frame sync is generated one clock cycle before the first output data.

Due to synchronization delays, the setup time for the receiver input is 1.5 FlexIO clock cycles, so the maximum baud rate is divide by 4 of the FlexIO clock frequency.

</tr>
</tbody>
</table>

50.4.7 I2S Slave

I2S slave mode can be supported using three Timers, two Shifters and four Pins (for single transmit and single receive, other combinations of transmit and receive are possible).

The transmit data must be written to the transmit buffer register before the external frame sync asserts, otherwise the shifter error flag will be set.

Due to synchronization delays, the output valid time for the serial output data is 2.5 FlexIO clock cycles, so the maximum baud rate is divide by 6 of the FlexIO clock frequency.

The output valid time of I2S slave is max 2.5 cycles because there is a maximum 1.5 cycle delay on the clock synchronization plus 1 cycle to output the data.

Timer 2 detects the falling edge of frame sync (start of new frame) and asserts output until falling edge of bit clock (when frame sync is normally sampled). Timer 0 detects falling edge of bit clock with Timer 2 output asserted and asserts output for length of frame. Timer 1 detects rising edge of bit clock with Timer 0 output asserted and controls shift registers for 32-bit transfers.

</tbody>
</table>
50.4.8 Camera Interface

Camera Interface can be supported using one Timer, one or more Shifters and multiple Pins. Multiple transfers can be supported using DMA controller.

The example below describes FlexIO configuration for interfacing to an 8-bit CMOS sensor with PCLK, VSYNC, HREF and D[7:0] outputs. The example uses a 128-bit buffer to capture 16-pixels of image data before interrupt or DMA transfer, however a bigger or smaller buffer may be used depending on system DMA performance and FlexIO resource usage by other applications. Note that additional timers may be used to track number of pixels per row and number of rows per frame or HREF/VSYNC may be assigned as GPIO interrupts for software tracking.

50.4.9  Motorola 68K/Intel 8080 Bus Interface

The Motorola 68K and Intel 8080 bus are two parallel interfaces commonly used by Smart/Asynchronous LCD controllers. In conjunction with GPIO, FlexIO is able to drive these interfaces using one Timer and one Shifter, although additional Shifters could be used to support large transfers via the DMA controller.

The configuration below provides an example of how to drive a 16-bit 68K or 8080 bus. For a 8080 bus, two GPIO are used to drive the nCS and RS pins. For a 68K bus, an additional GPIO is required to drive the RDWR pin.

</tr>
</tbody>
</table>

In general, any operation to a 68K/8080 bus slave will begin with a register write cycle followed by one or more data read or write cycles. To accomplish this, the following program flow should be used:

1. Configure FlexIO with 1-beat write configuration
2. Configure GPIO to assert nCS, RS pins (and deassert RDWR pin for 68K)
3. Write register index data to SHIFTBUF0[15:0]
4. Configure GPIO to deassert RS pin (and assert RDWR pin for 68K data read)
5. Configure FlexIO with desired read or write configuration (e.g. 1 or 16-beats)
6. Use the Shifter Status Flag to trigger interrupt or DMA driven data transfers to/from SHIFTBUF registers
7. Configure GPIO to deassert nCS pin

50.4.10 Low Power State Machine

The configuration below details a hypothetical state machine example to illustrate the flexibility allowed when using Shifter state mode.

In this example, FlexIO waits for the FXIO_D[2] pin to assert and then drives a complementary square wave output at a frequency of FLEXIO_CLK/131072 on the FXIO_D[1:0] pins while the comparator output is asserted (assumes comparator is
connected to external trigger 15, see Chip Configuration chapter for actual FlexIO trigger mappings). Throughout this operation, the CPU can be kept in a STOP/VLPS mode, by clearing the CTRL[DOZEN] bit and ensuring the FLEXIO_CLK is enabled. The state diagram below shows the states and transitions implemented by this example.

Shifter Error Flags

The shifter error flag is set when one of the following events occurs:

For SMOD=Receive, indicates Shifter was ready to store new data into SHIFTBUF before the previous data was read from SHIFTBUF (SHIFTBUF Overrun), or indicates that the received start or stop bit does not match the expected value.

For SMOD=Transmit, indicates Shifter was ready to load new data from SHIFTBUF before new data had been written into SHIFTBUF (SHIFTBUF Underrun).

For SMOD=Match Store, indicates a match event occurred before the previous match data was read from SHIFTBUF (SHIFTBUF Overrun).

For SMOD=Match Continuous, the error flag is set when a match has occurred between SHIFTBUF and Shifter.

For SMOD=Logic, the error flag is set when the output of the programmable logic block has asserted.

Can be cleared by writing logic one to the flag. For SMOD=Match Continuous, can also be cleared when the SHIFTBUF register is read.

0b - Shifter Error Flag is clear.
1b - Shifter Error Flag is set.

</tr>
</tbody>
</table>
| 3-0   | Timer Status Flags  

The timer status flag sets depending on the timer mode, and can be cleared by writing logic one to the flag. 

In 8-bit counter mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements, this also causes the counter to reload with the value in the compare register. 

In 8-bit PWM mode, the timer status flag is set when the upper 8-bit counter equals zero and decrements, this also causes the counter to reload with the value in the compare register. 

In 16-bit counter mode, the timer status flag is set when the 16-bit counter equals zero and decrements, this also causes the counter to reload with the value in the compare register.

- 0b - Timer Status Flag is clear.  
- 1b - Timer Status Flag is set.

### 50.5.1.15.3 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-21</td>
<td></td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
### Field: Parallel Width

For all Shifters, this register field configures the number of bits to be shifted on each Shift clock as follows:

- 1-bit shift for PWIDTH=0
- 4-bit shift for PWIDTH=1...3
- 8-bit shift for PWIDTH=4...7
- 16-bit shift for PWIDTH=8...15
- 32-bit shift for PWIDTH=16...31

For Shifters which support parallel transmit (SHIFTER0, SHIFTER4) or parallel receive (SHIFTER3, SHIFTER7), this register field, together with SHIFTCTL[PINSEL], also selects the pins to be driven or sampled on each Shift clock as follows:

FXIO_D[PINSEL+PWIDTH]:FXIO_D[PINSEL]

For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail.

### Field: Input Source

Selects the input source for the shifter.

- 0b - Pin
- 1b - Shifter N+1 Output

### Field: Shifter Stop bit

For SMOD=Transmit, this field allows automatic stop bit insertion if the selected timer has also enabled a stop bit.

For SMOD=Receive or Match Store, this field allows automatic stop bit checking if the selected timer has also enabled a stop bit.

For SMOD=State, this field is used to disable state outputs. See 'State Mode' section for more detail.

For SMOD=Logic, this field is used to mask logic pin inputs. See 'Logic Mode' section for more detail.

- 00b - Stop bit disabled for transmitter/receiver/match store
- 01b - Reserved for transmitter/receiver/match store
- 10b - Transmitter outputs stop bit value 0 on store, receiver/match store sets error flag if stop bit is not 0
- 11b - Transmitter outputs stop bit value 1 on store, receiver/match store sets error flag if stop bit is not 1

### Field: Shifter Start bit

For SMOD=Transmit, this field allows automatic start bit insertion if the selected timer has also enabled a start bit.
### Field Function

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-0</td>
<td>Shift Buffer</td>
</tr>
<tr>
<td>SHIFTBUF</td>
<td>Shift buffer data is used for a variety of functions depending on the SMOD setting:</td>
</tr>
</tbody>
</table>

For SMOD=Receive or Match Store, this field allows automatic start bit checking if the selected timer has also enabled a start bit.

For SMOD=State, this field is used to disable state outputs. See ‘State Mode’ section for more detail.

For SMOD=Logic, this field is used to mask logic pin inputs. See ‘Logic Mode’ section for more detail.

#### 50.5.1.16.3 Fields
Field | Function  
---|---
For SMOD=Receive, Shifter data is transferred into SHIFTBUF at the expiration of Timer. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available.
For SMOD=Transmit, SHIFTBUF data is transferred into the Shifter before the Timer begins.
For SMOD=Match Store, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask). The Match is checked when the Timer expires and Shifter data [31:16] is written to SHIFTBUF[31:16] whenever a match event occurs. The SHIFTBUF register should only be read when the corresponding shifter status flag is set, indicating new Shifter data is available.
For SMOD=Match Continuous, SHIFTBUF[31:16] contains the data to be matched with the Shifter contents and SHIFTBUF[15:0] can be used to mask the match result (1=mask, 0=no mask).
For SMOD=Logic, SHIFTBUF[31:0] is used to implement a 5-input, 32-bit programmable logic look-up table. See 'Logic Mode' section for more detail.
For SMOD=State, SHIFTBUF[31:24] is used to drive the output value when this shifter is selected by the current state pointer and SHIFTBUF[23:0] is used to configure the value of the next state transition. See 'State Mode' section for more detail.

<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>31-30</td>
<td>—</td>
</tr>
</tbody>
</table>

#### Field 29-24

TRGSEL

- Trigger Select

The valid values for TRGSEL will depend on the FLEXIO_PARAM register.

- When TRGSRC = 1, the valid values for N will depend on PIN, TIMER, SHIFTER fields in the FLEXIO_PARAM register.
- When TRGSRC = 0, the valid values for N will depend on TRIGGER field in FLEXIO_PARAM register.

Refer to the chip configuration section for external trigger selection.

**NOTE:** For a pin, N=0 to 31. For a Shifter/Timer, N=0 to 3.

The internal trigger selection is configured as follows:

- $4^*N$ - Pin $2^*N$ input
- $4^*N+1$ - Shifter $N$ status flag
- $4^*N+2$ - Pin $2^*N+1$ input
- $4^*N+3$ - Timer $N$ trigger output

#### Field 23

TRGPOL

- Trigger Polarity

i.MX RT1060 Processor Reference Manual, Rev. 2, 12/2019

NXP Semiconductors
50.5.1.21.2  Function

The options to enable or disable the timer using the Timer N-1 enable or disable are reserved when N is evenly divisible by 4 (eg: Timer 0).

NOTE
The pin and trigger level/edges specified below refer to the signal state after being modified by the PINPOL or TRGPOL setting in the TIMCTL register. For example, "Trigger low" means a trigger is actually at logic level 1 if the TRGPOL is set to 1 (active low).

---|---
15-0 | Timer Compare Value

The timer compare value is loaded into the timer counter when the timer is first enabled, when the timer is reset and when the timer decrements down to zero.

In 8-bit baud counter mode, the lower 8-bits configure the baud rate divider equal to \((\text{CMP}[7:0] + 1) * 2\). The upper 8-bits configure the number of bits in each word equal to \((\text{CMP}[15:8] + 1) / 2\).

In 8-bit PWM high mode, the lower 8-bits configure the high period of the output to \((\text{CMP}[7:0] + 1)\) and the upper 8-bits configure the low period of the output to \((\text{CMP}[15:8] + 1)\).

In 16-bit counter mode, the compare value can be used to generate the baud rate divider (if shift clock source is timer output) to equal \((\text{CMP}[15:0] + 1) * 2\). When the shift clock source is a pin or trigger input, the compare register is used to set the number of bits in each word equal to \((\text{CMP}[15:0] + 1) / 2\).

Chapter 51
Timers Overview

51.1 Overview
The following timers are supported in this chip:

- General Purpose Timer (GPT): A 32-bit up-counter with 12-bit pre-scaler
- Periodic Interrupt Timer (PIT): A 32-bit counter timer that features programmable count modulus, clock division features etc.
- Quad Timer (TMR): It provides four timer channels with variety of controls for individual and multi-channel features
- Quadrature Encoder/Decoder (ENC): It provides interfacing capability to position/speed sensors
- Enhanced FlexPWM: It contains PWM submodules each of which is set up to control a single half bridge power stage
- Watchdog Timer (WDOG1,2): The WDOG1 and WDOG2 protect against system failures by providing a method by which to escape from unexpected events or programming errors
- Watchdog timer (RTWDOG/WDOG3): It is a high reliability independent timer that is available for system use
- External Watchdog Monitor (EWM): It is designed to monitor external circuits, as well as the MCU software flow

51.1.1 General Purpose Timer (GPT)
The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge.

The GPT has a 12-bit pre-scaler, which provides a programmable clock frequency derived from multiple clock sources.
51.1.2 Periodic Interrupt Timer (PIT)

The PIT is a basic 32 bit counter timer. It features 32-bit counter timer, programmable count modulus, clock division features, interrupt generation, and a slave mode to synchronize count enable for multiple PITs.

51.1.3 Quad Timer (TMR)

The quad-timer provides four timer channels. Specific features include up/down count, cascading of counters, programmable modulo, count once/repeated, counter preload, compare registers with preload, shared use of input signals, prescaler controls, independent capture/compare, fault input control, programmable input filters, and multi-channel synchronization.

As shown in diagram below, input of QTimer can be sourced from PADs or XBAR1:

51.1.4 Enhanced Flex Pulse Width Modulator (eFlexPWM)

This module can generate various switching patterns, including highly sophisticated waveforms. Each module shall be configured with 4 channels supporting A, B, and X PWM output. All channels are configured for standard edge placement and have their capture function enabled.
51.1.5 Quadrature Encoder/Decoder (ENC)

The enhanced quadrature Encoder/decoder module provides interfacing capability to position/speed sensors used in industrial motor control applications. It has five input signals: PHASEA, PHASEB, INDEX, TRIGGER, and HOME. This module is used to decode shaft position, revolution count and speed.

51.1.6 Watchdog Timer (WDOG1,2)

The WDOG1 and WDOG2 protect against system failures by providing a method by which to escape from unexpected events or programming errors.

After WDOG1 and WDOG2 are activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG1 asserts the internal system reset signal, WDOG_RESET_B_DEB to the System Reset Controller (SRC); and WDOG2 asserts interrupt to SNVS to report the security violation condition.

51.1.7 Watchdog Timer (RTWDOG /WDOG3)

The WDOG3 module is an high reliability independent timer that is available for system use.

It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the MCU.

The WDOG3 clock can be sourced from:

- 1MHz RC OSC
- 32KHz clock generated by 32 KHZ XTALOSC which could be automatically switched to 32KHz RC OSC upon XTAL clock loss
- IP Bus Clock

51.1.8 External Watchdog Monitor (EWM)

The External Watchdog Monitor provides a back-up mechanism to the internal WDOG that can reset the system. The EWM differs from the internal WDOG in that it does not reset the system.
The EWM, if allowed to time-out, provides an independent trigger pin that when asserted resets or places an external circuit into a safe mode.

The EWM clock can be sourced from:

- 1MHz RC OSC
- 32KHz clock generated by 32 KHZ XTALOSC which could be automatically switched to 32KHz RC OSC upon XTAL clock loss
- IP Bus Clock

52.2 Overview

This chapter describes the General Purpose Timer (GPT) module interface. It is also a reference for software driver programming. The GPT has a 32-bit up-counter. The timer counter value can be captured in a register using an event on an external pin. The capture trigger can be programmed to be a rising or/and falling edge. The GPT can also generate an event on the output compare pins and an interrupt when the timer reaches a programmed value. The GPT has a 12-bit prescaler, which provides a programmable clock frequency derived from multiple clock sources.
Figure 52-1. GPT Block Diagram
52.2.1 Features

- One 32-bit up-counter with clock source selection, including external clock.
- Two input capture channels with a programmable trigger edge.
- Three output compare channels with a programmable output mode. A "forced compare" feature is also available.
- Can be programmed to be active in low power and debug modes.
- Interrupt generation at capture, compare, and rollover events.
- Restart or free-run modes for counter operations.

52.2.2 Modes and Operation

The GPT supports the modes described in the indicated sections:

- Operating Modes
  - Restart Mode
  - Free-Run Mode
52.3 External Signals

The GPT follows the IP Bus protocol for interfacing with the processor core. The GPT does not have any interface signals with any other module inside the chip, except for the clock and reset inputs (from the clock and reset controller module) and for the interrupt signals to the processor interrupt handler. There are functional and clock inputs, and functional output signals going outside the chip boundary.

The following table describes all block signals that connect off-chip.

Table 52-2. GPT External Signals

</tr>
</tbody>
</table>

There are six signals (three input, three output) in the GPT module that can be connected to the chip pads.

### 52.3.1 External Clock Input

The GPT counter can be operated using an external clock from outside the device, and this is the input pin used for that purpose. The external clock input (GPT_CLK) is treated as asynchronous to the peripheral clock (ipg_clk). To ensure proper operations of GPT, the external clock input frequency should be less than 1/4 of frequency of the peripheral clock (ipg_clk). Hysteresis characteristics on this pad will be required because this is a clock input.

### 52.3.2 Input Capture Trigger Signals

The GPT counter value can be stored in a register, triggered by an event from outside the device. A positive or/and negative edge on these signals GPT_CAPTURE1, GPT_CAPTURE2 can trigger this capture event. These signals are treated as asynchronous to the peripheral clock (ipg_clk). Only those transitions which occur at least a single clock cycle (the clock selected to run the counter) after the previous recorded transition are guaranteed to trigger a capture event.

### 52.3.3 Output Compare Signals

The output compare signals: GPT_COMPARE1, GPT_COMPARE2, GPT_COMPARE3, indicate that output compare events have gone through a specified transition.
52.4 Clocks

The clock that is input to the prescaler can be selected from 4 clock sources. The following table describes the clock sources for GPT. Please see Clock Controller Module (CCM) for clock setting, configuration and gating information.

Table 52-3. GPT Clocks

</tbody>
</table>

- **High-Frequency Clock (ipg_clk_highfreq)**

  Provided by the Clock Controller Module (CCM), the High Frequency Clock is intended to be ON in Normal Power mode when the Peripheral Clock (ipg_clk) is turned OFF, thereby enabling the GPT to be operated using the High Frequency Clock in Normal Power mode. The CCM is expected to provide this clock after synchronizing it to the System Bus Clock (ahb_clk) in Normal functional mode; the CCM is also expected to switch to the unsynchronized version of the High Frequency Clock in a Low Power mode.

- **Low-Reference Clock (ipg_clk_32k)**

  This 32 kHz Low Reference Clock (provided by the CCM) is intended to be ON in Low Power mode when the Peripheral Clock (ipg_clk) is turned OFF, thereby enabling the GPT to be operated using the Low Reference Clock in Low Power mode. The CCM is expected to provide the Low Reference Clock after synchronizing it to the System Bus Clock (ahb_clk) in Normal functional mode; the CCM is also expected to switch to the unsynchronized version of the Low Reference Clock in a Low Power mode.

- **Peripheral Clock (ipg_clk)**

  If the Peripheral Clock (ipg_clk) or the External Clock (GPT_CLK) is selected (CLKSRC=001 or 011) as Clock Source, then the Peripheral Clock will be ON in normal GPT operations. In Low Power modes, if the GPT is programmed to be disabled (STOPEN or WAITEN or DOZEN=0), then the Peripheral Clock (ipg_clk) can be switched OFF.

- **External Clock (GPT_CLK)**
The External Clock comes from outside the device and can be selected to run the GPT counter. The External Clock is treated as asynchronous to the Peripheral Clock, (ipg_clk) and is synchronized to the Peripheral Clock (ipg_clk), inside the module. Therefore, the External Clock frequency is limited to < 1/4 frequency of the Peripheral Clock (ipg_clk), for proper GPT operations. Note that in Low Power modes, if the Peripheral Clock (ipg_clk) is not available, then the External Clock cannot be used to run the counter.

- **Crystal Oscillator Clock (ipg_clk_24M)**

This 24 MHz Crystal Oscillator Clock (provided by the CCM) is intended to be used against frequency change of Peripheral Clock (ipg_clk) changes to provide a more accurate timer clock for operation system. The CCM is expected to provide the 24 MHz Crystal Oscillator Clock without synchronizing it to the System Bus Clock (ahb_clk) in Normal functional mode. Synchronization is done in GPT module. Before synchronization, the 24 MHz Crystal Oscillator Clock is divided by a 24 MHz clock prescaler, to make sure the clock frequency less than half of System Bus Clock (ahb_clk).

The clock input source is configured using the clock source field (CLKSRC, in the GPT_CR control register). The clock input to the prescaler can be disabled by programming the CLKSRC bits (of the GPT_CR control register) to 000. The **CLKSRC field value should be changed only after disabling the GPT** (by setting the EN bit in the GPT_CR to 0).

The PRESCALER field selects the divide ratio of the input clock that drives the main counter. The prescaler can divide the input clock by a value (from 1 to 4096) and can be changed at any time. A change in the value of the PRESCALER field immediately affects the output clock frequency.

![Prescaler Value Change Timing Diagram](image)

**Figure 52-3. Prescaler Value Change Timing Diagram**
52.5 Functional Description

This section provides a complete functional description of the GPT.

52.5.1 Operating Modes

The GPT counter can be programmed to work in either of two modes: Restart mode or Free-Run mode.

52.5.1.1 Restart Mode

In Restart mode (selectable through the GPT Control Register GPT_CR), when the counter reaches the compared value, the counter resets and starts again from 0x00000000. The Restart feature is associated only with Compare Channel 1.

Any write access to the Compare register of Channel 1 will reset the GPT counter. This is done to avoid possibly missing a compare event when compare value is changed from a higher value to lower value while counting is proceeding.

For the other two compare channels, when the compare event occurs the counter is not reset.

52.5.1.2 Free-Run Mode

In Free-Run mode, when compare events occur for all 3 channels, the counter is not reset; instead the counter continues to count until 0xffffffff, and then rolls over (to 0x00000000).

52.5.2 Operation

The General Purpose Timer (GPT) has a single counter (GPT_CNT) that is a 32-bit free-running up-counter, which starts counting after it is enabled by software (EN=1). The counter's clock source is the output of the prescaler labelled "Prescaler output" in Figure 52-1.

- If the GPT timer is disabled (EN=0), then the Main Counter and Prescaler Counter freeze their current count values. The ENMOD bit determines the value of the GPT counter when the EN bit is set and the Counter is enabled again.
• If the ENMOD bit is set (=1), then the Main Counter and Prescaler Counter values are reset to 0, when GPT is enabled (EN=1).
• If ENMOD bit is programmed to 0, then the Main Counter and Prescaler Counter restart counting from their frozen values, when GPT is enabled again (EN=1).
• If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter freeze at their current count values when GPT enters low power mode. When GPT exits a low power mode, the Main Counter and Prescaler Counter start counting from their frozen values regardless of the ENMOD bit value. Note that the GPT_CNT can be read at any time by the processor, and that both Input Capture Channels use the same counter (GPT_CNT).
• A hardware reset resets all the GPT registers to their respective reset values. All registers except the Output Compare Registers (OCR1, OCR2, OCR3) obtain a value of 0x0. The Compare registers are reset to 0xFFFF_FFFF.
• The software reset (SWR bit in the GPT_CR control register) resets all of the register bits except the EN, ENMOD, STOPEN, WAITEN, and DBGEN bits. The state of these bits is not affected by a software reset. Note that a software reset can be given while the GPT is disabled.

52.5.2.1 Input Capture

There are two Input Capture Channels, and each Input Capture Channel has a dedicated capture pin, capture register and input edge detection/selection logic. Each input capture function has an associated status flag, and can cause the processor to make an interrupt service request.

When a selected edge transition occurs on an Input Capture pin, the contents of the GPT_CNT is captured on the corresponding capture register and the appropriate interrupt status flag is set. An interrupt request can be generated when the transition is detected if its corresponding enable bit is set (in the Interrupt Register). The capture can be programmed to occur on the input pin's rising edge, falling edge, on both rising and falling edges, or the capture can be disabled. The events are synchronized with the clock that was selected to run the counter. Only those transitions that occur at least one clock cycle (clock selected to run the counter) after the previous recorded transition will be guaranteed to trigger a capture event. There can be up to one clock cycle of uncertainty in the latching of the input transition. The Input Capture registers can be read at any time without affecting their values.
52.5.2.2 Output Compare

The three Output Compare Channels use the same counter (GPT_CNT) as the Input Capture Channels. When the programmed content of an Output Compare register matches the value in GPT_CNT, an output compare status flag is set and an interrupt is generated (if the corresponding bit is set in the interrupt register). Consequently, the Output Compare timer pin will be set, cleared, toggled, not affected at all or provide an active-low pulse for one input clock period (subject to the restriction on the maximum frequency allowed on the pad) according to the mode bits (that were programmed).

There is also a "forced-compare" feature that allows the software to generate a compare event when required, without the condition of the counter value that is equal to the compare value. The action taken as a result of a forced compare is the same as when an output compare match occurs, except that the status flags are not set and no interrupt can be generated. Forced channels take programmed action immediately after the write to the force-compare bits. These bits are self-negating and always read as zeros.
52.5.2.3 Interrupts

There are 6 different interrupts that are generated by the GPT. If the selected clock for running the counter is available, then all interrupts can be generated in Low Power and Debug modes.

- Rollover Interrupt

The Rollover Interrupt is generated when the GPT counter reaches 0xffffffff, then resets to 0x00000000 and continues counting. The Rollover Interrupt is enabled by the ROVIE bit in the GPT_IR register; the associated status bit is the ROV bit in the GPT_SR register.

- Input Capture Interrupt 1, 2

After a capture event occurs, the associated Input Capture Channel generates an interrupt. The "capture event" interrupts are enabled by the IF2IE and IF1IE bits (in the GPT_IR register); the associated status bits are IF2 and IF1 (in the GPT_SR register). The capture of the counter value because of a capture event is not affected by a pending capture interrupt. The Capture register is updated with a new counter value when a capture event occurs, regardless of whether that Capture Channels' interrupt has been serviced or not.

- Output Compare Interrupt 1, 2, 3
After a compare event occurs, the associated Output Compare Channel generates an interrupt. The "compare event" interrupts are enabled by the OF3IE, OF2IE, and OF1IE bits (in the GPT_IR register); the associated status bits are OF3, OF2, and OF1 (in the GPT_SR register). A "forced compare" does not generate an interrupt.

A cumulative interrupt line is also present, which is asserted whenever any of the above interrupts are posted. The cumulative interrupt line has no associated enables or status bits.

### 52.5.2.4 Low Power Mode Behavior

In Low Power modes, if the clock from the selected clock source is available (except for the External Clock (GPT_CLK), which can be used only if the Peripheral Clock (ipg_clk) is available), the counter will continue to run depending on whether the control bit for that mode is set. If the clock is not present or if the corresponding low power bit in the GPT_CR control register is 0, the Main Counter and the Prescaler Counter freeze at their current values and resume counting (from their frozen values) when the Low Power mode is exited.

### 52.5.2.5 Debug Mode Behavior

In Debug mode, the modules in the device have the option of continuing to run or be halted.

- If the DBGEN bit is set, then the GPT timer will continue to run in Debug mode.
- If the DBGEN bit is not set (in the GPT_CR control register), then the GPT timer is halted.

### 52.6 Initialization/ Application Information

#### 52.6.1 Selecting the Clock Source

The CLKSRC field in the GPT_CR register selects the clock source. The CLKSRC field value should be changed only after disabling the GPT (EN=0).

The software sequence to be followed while changing clock source is:

1. Disable GPT by setting EN=0 in GPT_CR register.
2. Disable GPT interrupt register (GPT_IR).
3. Configure Output Mode to unconnected/disconnected—Write zeros in OM3, OM2, and OM1 in GPT_CR
4. Disable Input Capture Modes—Write zeros in IM1 and IM2 in GPT_CR
5. Change clock source CLKSRC to the desired value in GPT_CR register.
6. Assert the SWR bit in GPT_CR register.
7. Clear GPT status register (GPT_SR) (i.e., w1c).
8. Set ENMOD=1 in GPT_CR register, to bring GPT counter to 0x00000000.
9. Enable GPT (EN=1) in GPT_CR register.
10. Enable GPT interrupt register (GPT_IR).

52.7 GPT Memory Map/Register Definition

The GPT has 10 user-accessible 32-bit registers, which are used to configure, operate, and monitor the state of the GPT.

An IP bus write access to the GPT Control Register (GPT_CR) and the GPT Output Compare Register1 (GPT_OCR1) results in one cycle of wait state, while other valid IP bus accesses incur 0 wait states.

Irrespective of the Response Select signal value, a Write access to the GPT Status Registers (Read-only registers GPT_ICR1, GPT_ICR2, GPT_CNT) will generate a bus exception.

- If the Response Select signal is driven Low, then the Read/Write access to the unimplemented address space of GPT (ips_addr is greater than or equal to $BASE + $028) will generate a bus exception.
- If the Response Select is driven High, then the Read/Write access to the unimplemented address space of GPT will not generate any error response (like a bus exception).

</tbody>
</table>

The OMₙ bits specify the response that a compare event will generate on the output pin of Output Compare Channel n.

- The toggle, clear, and set options cause a change on the output pin only if a compare event occurs.
- When OMₙ is programmed as 1xx (active low pulse), the output pin is set to one immediately on the next input clock; a low pulse (that is an input clock in width) occurs when there is a compare event. Note that here, "input clock" refers to the clock selected by the CLKSRC bits of the GPT Control Register.

<table>

## GPTx_CR field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| • A hardware reset resets the EN_24M bit.  
• A software reset *does not affect* the EN_24M bit. | |
| 0 | 24M clock disabled |
| 1 | 24M clock enabled |

| 9 | FRR | Free-Run or Restart mode.  
The FFR bit determines the behavior of the GPT when a compare event in channel 1 occurs.  
• In Restart mode, after a compare event, the counter resets to 0x00000000 and resumes counting (after the occurrence of a compare event).  
• In Free-Run mode, after a compare event, the counter continues counting until 0xFFFFFFFF and then rolls over to 0. |
| 0 | Restart mode |
| 1 | Free-Run mode |

| 8–6 | CLKSRC | Clock Source select.  
The CLKSRC bits select which clock will go to the prescaler (and subsequently be used to run the GPT counter).  
• The CLKSRC bit field value should only be changed after disabling the GPT by clearing the EN bit in this register (GPT_CR).  
• A software reset does not affect the CLKSRC bit. |
| 000 | No clock |
| 001 | Peripheral Clock (ipg_clk) |
| 010 | High Frequency Reference Clock (ipg_clk_highfreq) |
| 011 | External Clock |
| 100 | Low Frequency Reference Clock (ipg_clk_32k) |
| 101 | Crystal oscillator as Reference Clock (ipg_clk_24M) |
| others | Reserved |

| 5 | STOPEN | GPT Stop Mode enable.  
The STOPEN read/write control bit enables GPT operation *during Stop mode*.  
• A hardware reset resets the STOPEN bit.  
• A software reset *does not affect* the STOPEN bit. |
| 0 | GPT is disabled in Stop mode. |
| 1 | GPT is enabled in Stop mode. |

| 4 | DOZEEN | GPT Doze Mode Enable.  
• A hardware reset resets the DOZEEN bit.  
• A software reset *does not affect* the DOZEEN bit. |
| 0 | GPT is disabled in doze mode. |
| 1 | GPT is enabled in doze mode. |

| 3 | WAITEN | GPT Wait Mode enable.  
The WAITEN read/write control bit enables GPT operation *during Wait mode*.  
• A hardware reset resets the WAITEN bit.  
• A software reset *does not affect* the WAITEN bit. |
| 0 | GPT is disabled in wait mode. |
| 1 | GPT is enabled in wait mode. |

*Table continues on the next page...*
### GPTx_CR field descriptions (continued)

<table>
<thead>
<tr>

<th>Description</th>
</tr>
</thead>
</table>
| 2     | GPT debug mode enable.  
The DBGEN read/write control bit enables GPT operation during Debug mode.  
• A hardware reset resets the DBGEN bit.  
• A software reset does not affect the DBGEN bit.  
| 0     | GPT is disabled in debug mode.  
| 1     | GPT is enabled in debug mode.  |

1 ENMOD  
GPT Enable mode.  
When the GPT is disabled (EN=0), then both the Main Counter and Prescaler Counter freeze their current count values. The ENMOD bit determines the value of the GPT counter when Counter is enabled again (if the EN bit is set).  
• If the ENMOD bit is 1, then the Main Counter and Prescaler Counter values are reset to 0 after GPT is enabled (EN=1).  
• If the ENMOD bit is 0, then the Main Counter and Prescaler Counter restart counting from their frozen values after GPT is enabled (EN=1).  
• If GPT is programmed to be disabled in a low power mode (STOP/WAIT), then the Main Counter and Prescaler Counter freeze at their current count values when the GPT enters low power mode.  
• When GPT exits low power mode, the Main Counter and Prescaler Counter start counting from their frozen values, regardless of the ENMOD bit value.  
• Setting the SWR bit will clear the Main Counter and Prescaler Counter values, regardless of the value of EN or ENMOD bits.  
• A hardware reset resets the ENMOD bit.  
• A software reset does not affect the ENMOD bit.  
| 0     | GPT counter will retain its value when it is disabled.  
| 1     | GPT counter value is reset to 0 when it is disabled.  |

0 EN  
GPT Enable.  
The EN bit is the GPT module enable bit.  
**Before setting the EN bit, we recommend that all registers be properly programmed.**  
• A hardware reset resets the EN bit.  
• A software reset does not affect the EN bit.  
| 0     | GPT is disabled.  
| 1     | GPT is enabled.  |
52.7.2 GPT Prescaler Register (GPTx_PR)

The GPT Prescaler Register (GPT_PR) contains bits that determine the divide value of the clock that runs the counter.

## 52.7.3 GPT Status Register (GPTx_SR)

The GPT Status Register (GPT_SR) contains bits that indicate that a counter has rolled over, and if any event has occurred on the Input Capture and Output Compare channels. The bits are cleared by writing a 1 to them.

**Address:** Base address + 8h offset

52.7.5 GPT Output Compare Register 1 (GPTx_OCR1)

The GPT Compare Register 1 (GPT_OCR1) holds the value that determines when a compare event will be generated on Output Compare Channel 1. Any write access to the Compare register of Channel 1 while in Restart mode (FRR=0) will reset the GPT counter.

An IP Bus Write access to the GPT Output Compare Register1 (GPT_OCR1) occurs after one cycle of wait state; an IP Bus Read access occurs immediately (0 wait states).

There are 4 PIT channels in this device.

53.2 Introduction

The PIT module is an array of timers that can be used to raise interrupts and trigger DMA channels.

53.2.1 Block diagram

The following figure shows the block diagram of PIT module.
53.2.2 Features

The key features of the module are these:

- Ability of timers to generate DMA trigger pulses
- Ability of timers to generate interrupts
- Maskable interrupts
- Independent timeout periods for each timer
53.3 Modes of operation

This subsection briefly describes all operating modes supported by PIT.

- Run mode
  All functional parts of the PIT are running during normal Run mode.
- Stop mode

53.4 PIT External Signals

<table>

</tr>
</tbody>
</table>

53.5 Functional description

This section provides the functional description of the module.

53.5.1 General operation

This section provides detailed information on the internal operation of the module. Each timer can be used to generate trigger pulses and interrupts, and each interrupt is available on a separate interrupt line.

53.5.1.1 Timers

The timers generate triggers at periodic intervals, when enabled. The timers load the start values as specified in their LDVAL registers, count down to 0 and then load the respective start values again. Each time a timer reaches 0, it generates a trigger pulse and sets the interrupt flag.

All interrupts can be enabled or masked by setting TCTRLn[TIE]. A new interrupt can be generated only after the previous one is cleared.

If desired, the current counter value of the timer can be read via the CVAL registers.
The counter period can be restarted by first disabling and then enabling the timer with TCTRLn[TEN]. See the following figure.

![Figure 53-2. Stopping and starting a timer](image)

The counter period of a running timer can be modified by first disabling the timer, setting a new load value, and then enabling the timer again. See the following figure.

![Figure 53-3. Modifying running timer period](image)

It is also possible to change the counter period without restarting the timer, by writing LDVAL with the new load value. This value then loads after the next trigger event. See the following figure.

![Figure 53-4. Dynamically setting a new load value](image)

**NOTE**

- If the pause is initiated, when the timer is nearing 0 (CVALn =0x0), the pause command may not make it to the IP before the timer expires and generates a trigger.
• Pause will be ignored if (CVALn =0x0), but the trigger will remain asserted until the pause is removed. The user is recommended to remove Pause and then clear the interrupt TFLGn[TIF].

• If the timers are to be paused, sufficient time must be ensured for the IP to react.

53.5.1.2 Debug mode

In the Debug mode, the timers are frozen based on MCR[FRZ]. This is intended to aid software development, allowing the developer to halt the processor, investigate the current state of the system, for example, the timer values, and then continue the operation.

53.5.2 Interrupts

All the timers support interrupt generation. See the MCU specification for related vector addresses and priorities.

Timer interrupts can be enabled by setting TCTRLn[TIE].

TFLGn[TIF] are set to 1 when a timeout occurs on the associated timer, and are cleared to 0 by writing a 1 to the corresponding TFLGn[TIF].

53.5.3 Chained timers

When a timer has chain mode enabled, it counts after the previous timer has expired. So if timer n-1 counts down to 0, counter n decrements the value by one. This allows to chain some of the timers together to form a longer timer. The first timer (timer 0) cannot be chained to any other timer.

53.6 Initialization and application information

In the example configuration:

• The PIT clock has a frequency of 50 MHz.
• Timer 1 creates an interrupt every 5.12 ms.
• Timer 3 creates a trigger event every 30 ms.

The PIT module must be activated by writing a 0 to MCR[MDIS].

The 50 MHz clock frequency equates to a clock period of 20 ns. Timer 1 needs to trigger every 5.12 ms/20 ns = 256,000 cycles and Timer 3 every 30 ms/20 ns = 1,500,000 cycles. The value for the LDVAL register trigger is calculated as:

\[
LDVAL \text{ trigger} = \frac{\text{period}}{\text{clock period}} - 1
\]

This means LDVAL1 and LDVAL3 must be written with 0x0003E7FF and 0x0016E35F, respectively.

The interrupt for Timer 1 is enabled by setting TCTRL1[TIE]. The timer is started by writing 1 to TCTRL1[TEN].

Timer 3 shall be used only for triggering. Therefore, Timer 3 is started by writing a 1 to TCTRL3[TEN]. Also, TCTRL3[TIE] stays at 0.

The following example code matches the described setup:

```c
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0x0003E7FF; // setup timer 1 for 256000 cycles
PIT_TCTRL1 = TIE; // enable Timer 1 interrupts
PIT_TCTRL1 |= TEN; // start Timer 1

// Timer 3
PIT_LDVAL3 = 0x0016E35F; // setup timer 3 for 1500000 cycles
PIT_TCTRL3 |= TEN; // start Timer 3
```

53.7 Example configuration for chained timers

In the example configuration:

• The PIT clock has a frequency of 100 MHz.
• Timers 1 and 2 are available.
• An interrupt is raised every 1 minute.

The PIT module needs to be activated by writing a 0 to MCR[MDIS].
Chapter 53 Periodic Interrupt Timer (PIT)

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN].

TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```c
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

53.8 Example configuration for the lifetime timer

To configure the lifetime timer, channels 0 and 1 need to be chained together.

First, the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, and then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```c
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1
```

Chapter 53 Periodic Interrupt Timer (PIT)

The 100 MHz clock frequency equates to a clock period of 10 ns, so the PIT needs to count for 6000 million cycles, which is more than a single timer can do. So, Timer 1 is set up to trigger every 6 s (600 million cycles). Timer 2 is chained to Timer 1 and programmed to trigger 10 times.

The value for the LDVAL register trigger is calculated as number of cycles-1, so LDVAL1 receives the value 0x23C345FF and LDVAL2 receives the value 0x00000009.

The interrupt for Timer 2 is enabled by setting TCTRL2[TIE], the Chain mode is activated by setting TCTRL2[CHN], and the timer is started by writing a 1 to TCTRL2[TEN].

TCTRL1[TEN] needs to be set, and TCTRL1[CHN] and TCTRL1[TIE] are cleared.

The following example code matches the described setup:

```c
// turn on PIT
PIT_MCR = 0x00;

// Timer 2
PIT_LDVAL2 = 0x00000009; // setup Timer 2 for 10 counts
PIT_TCTRL2 = TIE; // enable Timer 2 interrupt
PIT_TCTRL2 |= CHN; // chain Timer 2 to Timer 1
PIT_TCTRL2 |= TEN; // start Timer 2

// Timer 1
PIT_LDVAL1 = 0x23C345FF; // setup Timer 1 for 600 000 000 cycles
PIT_TCTRL1 = TEN; // start Timer 1
```

53.8 Example configuration for the lifetime timer

To configure the lifetimer timer, channels 0 and 1 need to be chained together.

First, the PIT module needs to be activated by writing a 0 to the MDIS bit in the CTRL register, and then the LDVAL registers need to be set to the maximum value.

The timer is a downcounter.

The following example code matches the described setup:

```c
// turn on PIT
PIT_MCR = 0x00;

// Timer 1
PIT_LDVAL1 = 0xFFFFFFFF; // setup timer 1 for maximum counting period
PIT_TCTRL1 = 0x0; // disable timer 1 interrupts
PIT_TCTRL1 |= CHN; // chain timer 1 to timer 0
PIT_TCTRL1 |= TEN; // start timer 1
```
To access the lifetime, read first LTMR64H and then LTMR64L.

```c
current_uptime = PIT_LTMR64H<<32;
current_uptime = current_uptime + PIT_LTMR64L;
```

## 53.9 PIT register descriptions

This section provides a detailed description of all registers accessible in the PIT module.

- See the chip-specific PIT information for the number of PIT channels used in this MCU.

53.9.4.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>LTMR64L</td>
<td>E4h</td>
</tr>
</tbody>
</table>

53.9.4.2 Function

This register is intended for applications that chain timer 0 and timer 1 to build a 64-bit lifetimer.

To use LTMR64H and LTMR64L, timer 0 and timer 1 need to be chained. To obtain the correct value, first read LTMR64H and then LTMR64L. The value for the LTMR64H register is set to CVAL1 register at the time of the first access and the value of the LTMR64L register is set to CVAL0 register at first access. Therefore, the application is not affected by the carry-over effects of the running counter.

54.2 Overview

Each timer module (TMR) contains four identical counter/timer groups. Each 16-bit counter/timer group contains a prescaler, a counter, a load register, a hold register, a capture register, two compare registers, two status and control registers, and one control register. All of the registers except the prescaler are read/writeable.

**NOTE**
This document uses the terms "Timer" and "Counter" interchangeably because the counter/timers may perform either or both tasks.

The load register provides the initialization value to the counter when the counter's terminal value has been reached.
The hold register captures the counter's value when other counters are being read. This feature supports the reading of cascaded counters.

The capture register enables an external signal to take a "snap shot" of the counter's current value.

The COMP1 and COMP2 registers provide the values to which the counter is compared. If a match occurs, the OFLAG (TMR Output signal) can be set, cleared, or toggled. At match time, an interrupt is generated if enabled, and the new compare value is loaded into the COMP1 or COMP2 registers from CMPLD1 and CMPLD2 if enabled.

The prescaler provides different time bases useful for clocking the counter/timer.

The counter provides the ability to count internal or external events.

Within a timer module (set of four timer/counters), the input pins are shareable.

54.3 Features

The TMR module design includes these distinctive features:

- Four 16-bit counters/timers
- Count up/down
- Counters are cascadable
- Programmable count modulo
- Max count rate equals peripheral clock/2 for external clocks
- Max count rate equals peripheral clock for internal clocks
- Count once or repeatedly
- Counters are preloadable
- Compare registers are preloadable (available with compare load feature)
- Counters can share available input pins
- Separate prescaler for each counter
- Each counter has capture and compare capability
- Programmable operation during debug mode
- Inputs may act as fault inputs
• Programmable input filter
• Counting start can be synchronized across counters

54.4 Modes of Operation
The TMR module design operates in only a single mode of operation: Functional Mode. The various counting modes are detailed in the Functional Description.

54.5 Block Diagram
Each of the timer/counter groups within the quad-timer are shown in this figure.

![Quad Timer Block Diagram](image-url)

Figure 54-1. Quad Timer Block Diagram
54.6 Memory Map and Registers

The address of a register is the sum of a base address and an address offset. The base address is defined at the chip level and the address offset is defined at the module level. Make certain to check which quad timer is available on the chip being used, and which timer channels have external I/O.

TCFx_SCTRLn field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 15 TCF| Timer Compare Flag  
This bit is set when a successful compare occurs. This bit is cleared by writing a zero to this bit location. |
| 14 TCFIE| Timer Compare Flag Interrupt Enable  
This bit (when set) enables interrupts when TCF is set. |
| 13 TOF| Timer Overflow Flag  
This bit is set when the counter rolls over its maximum value $FFFF or $0000 (depending on count direction). This bit is cleared by writing a zero to this bit location. |
| 12 TOFIE| Timer Overflow Flag Interrupt Enable  
This bit (when set) enables interrupts when TOF is set. |
| 11 IEF| Input Edge Flag  
This bit is set when CAPTMODE is enabled and a proper input transition occurs (on an input selected as a secondary count source) while the count mode does not equal 000. This bit is cleared by writing a zero to this bit position. This bit can also be cleared automatically by a read of CAPT when DMA[IEFDE] is set. 
NOTE: Setting the input polarity select bit (IPS) changes the edge to be detected. Also, the control register’s secondary count source determines which external input pin is monitored by the detection circuitry. |
| 10 IEFIE| Input Edge Flag Interrupt Enable  
This bit (when set) enables interrupts when IEF is set. 
Restriction: Do not set both this bit and DMA[IEFDE]. |
| 9 IPS| Input Polarity Select  
This bit (when set) inverts the input signal polarity. |
| 8 INPUT| External Input Signal  
This read-only bit reflects the current state of the external input pin selected via the secondary count source after application of IPS and filtering. |

### TMRx_SCTRLn field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| **7–6 CAPTURE_MODE** | Input Capture Mode  
These bits specify the operation of the capture register as well as the operation of the input edge flag. The input source is the secondary count source.  
00 Capture function is disabled  
01 Load capture register on rising edge (when IPS=0) or falling edge (when IPS=1) of input  
10 Load capture register on falling edge (when IPS=0) or rising edge (when IPS=1) of input  
11 Load capture register on both edges of input |
| **5 MSTR** | Master Mode  
This bit (when set) enables the compare function's output to be broadcasted to the other counters/timers in the module. This signal then can be used to re-initialize the other counters and/or force their OFLAG signal outputs. |
| **4 EEOF** | Enable External OFLAG Force  
This bit (when set) enables the compare from another counter/timer within the same module to force the state of this counter's OFLAG output signal. |
| **3 VAL** | Forced OFLAG Value  
This bit determines the value of the OFLAG output signal when software triggers a FORCE command. |
| **2 FORCE** | Force OFLAG Output  
This write only bit forces the current value of VAL to be written to the OFLAG output. This bit always reads as a zero. VAL and FORCE can be written simultaneously in a single write operation. Write to FORCE only if the counter is disabled. Setting this bit while the counter is enabled may yield unpredictable results. |
| **1 OPS** | Output Polarity Select  
This bit determines the polarity of the OFLAG output signal.  
0 True polarity.  
1 Inverted polarity. |
| **0 OEN** | Output Enable  
This bit determines the direction of the external pin.  
0 The external pin is configured as an input.  
1 The OFLAG output signal is driven on the external pin. Other timer groups using this external pin as their input see the driven value. The polarity of the signal is determined by OPS. |

### 54.6.12 Timer Channel Input Filter Register (TMRx_FILTn)

The FILT register programs the values for the filtering of the corresponding input without regard for the fact that any timer channel can use the input as a count source.

Input filter considerations:
- Set the FILT_PER value such that the sampling period is larger than the period of the expected noise. In this way, a noise spike will corrupt only one sample. Choose the FILT_CNT value to reduce the probability that noisy samples cause an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of (FILT_CNT + 3).
- The values of FILT_PER and FILT_CNT must also be balanced against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of (((FILT_CNT + 3) x FILT_PER) + 2) IP bus clock periods.

### 54.7 Functional Description

#### 54.7.1 General

The counter/timer has two basic modes of operation: it can count internal or external events, or it can count an internal clock source while an external input signal is asserted, thus timing the width of the external input signal.

- The counter can count the rising, falling, or both edges of the selected input pin.
- The counter can decode and count quadrature encoded input signals.
- The counter can count up and down using dual inputs in a "count with direction" format.
- The counter's terminal count value (modulo) is programmable.
- The value that is loaded into the counter after reaching its terminal count is programmable.
• The counter can count repeatedly, or it can stop after completing one count cycle.

• The counter can be programmed to count to a programmed value and then immediately reinitialize, or it can count through the compare value until the count "rolls over" to zero.

The external inputs to each counter/timer are shareable among each of the four counter/timers within the module. The external inputs can be used as:

• Count commands

• Timer commands

• They can trigger the current counter value to be "captured"

• They can be used to generate interrupt requests

The polarity of the external inputs are selectable.

The primary output of each timer/counter is the output signal OFLAG. The OFLAG output signal can be:

• Set, cleared, or toggled when the counter reaches the programmed value.

• The OFLAG output signal may be output to an external pin instead of having that pin serve as a timer input.

• The OFLAG output signal enables each counter to generate square waves, PWM, or pulse stream outputs.

• The polarity of the OFLAG output signal is selectable.

Any counter/timer can be assigned as a master. A master's compare signal can be broadcast to the other counter/timers within the module. The other counters can be configured to reinitialize their counters and/or force their OFLAG output signals to predetermined values when a master's counter/timer compare event occurs.

### 54.7.2 Usage of Compare Registers

The dual compare registers (COMP1 and COMP2) provide a bidirectional modulo count capability. The COMP1 register is used when the counter is counting up, and the COMP2 register is used when the counter is counting down. Alternating compare mode is the only exception.
The COMP1 register should be set to the desired maximum count value or FFFFH to indicate the maximum unsigned value prior to roll-over, and the COMP2 register should be set to the minimum count value or 0000h to indicate the minimum unsigned value prior to roll-under.

If CTRL[OUTMODE] is set to 100, the OFLAG will toggle while using alternating compare registers. In this variable frequency PWM mode, the COMP2 value defines the desired pulse width of the on time, and the COMP1 register defines the off time.

Use caution when changing COMP1 and COMP2 while the counter is active. If the counter has already passed the new value, it will count to FFFFH or 0000h, roll over, then begin counting toward the new value. The check is: Count=CMPx, not Count > COMP1 or Count < COMP2.

The use of the CMPLD1 and CMPLD2 registers to compare values will help to minimize this problem.

### 54.7.3 Usage of Compare Load Registers

The CMPLD1, CMPLD2, and CSCTRL registers offer a high degree of flexibility for loading compare registers with user-defined values on different compare events. To ensure correct functionality while using these registers we strongly suggest using the following method described in this section.

The purpose of the compare load feature is to allow quicker updating of the compare registers. In the past, a compare register could be updated using interrupts. However, because of the latency between an interrupt event occurring and the service of that interrupt, there was the possibility that the counter may have already counted past the new compare value by the time the compare register was updated by the interrupt service routine. The counter would then continue counting until it rolled over and reached the new compare value.

To address this, the compare registers are now updated in hardware in the same way the counter register is re-initialized to the value stored in the load register. The compare load feature allows the user to calculate new compare values and store them in to the comparator load registers. When a compare event occurs, the new compare values in the comparator load registers are written to the compare registers eliminating the use of software to do this.
The compare load feature is intended to be used in variable frequency PWM mode. The COMP1 register determines the pulse width for the logic low part of OFLAG and COMP2 determines the pulse width for the logic high part of OFLAG. The period of the waveform is determined by the COMP1 and COMP2 values and the frequency of the primary clock source. See the following figure.

![Variable PWM Waveform](image)

Figure 54-2. Variable PWM Waveform

Should we desire to update the duty cycle or period of the above waveform, we would need to update the COMP1 and COMP2 values using the compare load feature.

### 54.7.4 Usage of the Capture Register

The capture register stores a copy of the counter's value when an input edge (positive, negative, or both) is detected. After a capture event occurs, no further updating of the capture register will occur until the SCTRL[IEF] (input edge flag) is cleared by writing a zero to the SCTRL[IEF].

### 54.7.5 Functional Modes

The selected external count signals are sampled at the TMR's base clock rate and then run through a transition detector. The maximum count rate is one-half of the TMR's base clock rate. Internal clock sources can be used to clock the counters at the TMR's base clock rate.

If a counter is programmed to count to a specific value and then stop, the CTRL[CM] field is cleared when the count terminates.
54.7.5.1  Stop Mode

If CTRL[CM] is set to '000', the counter is inert. No counting will occur. Stop mode will also disable the interrupts caused by input transitions on a selected input pin.

54.7.5.2  Count Mode

If CTRL[CM] is set to '001', the counter will count the rising edges of the selected clock source. This mode is useful for generating periodic interrupts for timing purposes, or counting external events such as "widgets" on a conveyor belt passing a sensor. If the selected input is inverted by setting SCTRL[IPS] (input polarity select), then the negative edge of the selected external input signal is counted.

Example: 54.7.5.2.1  Count Pulses from External Source

```c
void Pulse_Init(void)
{
/* TMR1_CTRL: CM=0,PCS=3,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
setReg(TMR1_CTRL,0x0600); /* Set up mode */
/* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
setReg(TMR1_SCTRL,0x00);
setReg(TMR1_CNTR,0x00); /* Reset counter register */
setReg(TMR1_LOAD,0x00); /* Reset load register */
setRegBitGroup(TMR1_CTRL,CM,0x01); /* Run counter */
}
```

Example: 54.7.5.2.2  Generate Periodic Interrupt By Counting Internal Clocks

```c
void TimerInt_Init(void)
{
/* TMR0_CTRL: CM=0,PCS=0,SCS=0,ONCE=0,LENGTH=1,DIR=0,COINIT=0,OUTMODE=0 */
setReg(TMR0_CTRL,0x20); /* Stop all functions of the timer */
/* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
setReg(TMR0_SCTRL,0x00);
```
54.7.5.3 Edge-Count Mode
If CTRL[CM] is set to '010', the counter will count both edges of the selected external clock source. This mode is useful for counting the changes in the external environment, such as a simpleencoder wheel.

Example: 54.7.5.3.1 Count Both Edges of External Source Signal

```c
void Pulse_Init(void)
{
    /* TMR1_CTRL: CM=0,PCS=3,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMR1_CTRL,0x0600); /* Set up mode */
    /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
        Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,CEN=0 */
    setReg(TMR1_SCTRL,0x00);
    setReg(TMR1_CNTR,0x00); /* Reset counter register */
    setReg(TMR1_LOAD,0x00); /* Reset load register */
    setRegBitGroup(TMR1_CTRL,CM,0x02); /* Run counter */
}
```

54.7.5.4 Gated-Count Mode
If CTRL[CM] is set to '011', the counter will count while the selected secondary input signal is high. This mode is used to time the duration of external events. If the selected input is inverted by setting SCTRL[IPS] (input polarity select), then the counter will count while the selected secondary input is low.

Example: 54.7.5.4.1 Capture Duration of External Pulse
54.7.5.5 Quadrature-Count Mode

If CTRL[CM] is set to '100', the counter will decode the primary and secondary external inputs as quadrature encoded signals. Quadrature signals are usually generated by rotary or linear sensors used to monitor movement of motor shafts or mechanical equipment. The quadrature signals are square waves that are 90 degrees out of phase. The decoding of quadrature signal provides both count and direction information.

This figure shows a timing diagram illustrating the basic operation of a quadrature incremental position encoder.

![Figure 54-3. Quadrature Incremental Position Encoder](image)

**Example: 54.7.5.5.1 Quadrature Count Mode Example**

```c
void Pulse_Init(void)
{
    /* TMR1_CTRL: CM=0,PCS=8,SCS=1,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMR1_CTRL,0x1080);            /* Set up mode */
    /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
        Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
    setReg(TMR1_SCTRL,0x00);
    setReg(TMR1_CNTR,0x00);             /* Reset counter register */
    setReg(TMR1_LOAD,0x00);             /* Reset load register */
    setRegBitGroup(TMR1_CTRL,CM,0x03);  /* Run counter */
}
```
54.7.5.6 Quadrature-Count Mode with Index Input

As an extension to the quadrature count mode discussed in the previous paragraph, some rotary shafts have a HOME or INDEX indicator. This would be a third input to the timer that is used to reset the timer's counter.

In this example, channel 0 is used to decode the quadrature inputs, but it doesn't actually count. Because its upper and lower limits are both set to 0, its output is cascaded count up and count down signals each time the quadrature inputs indicate a change in count.

Channel 1 works in cascaded count mode receiving its counting instructions from channel 0. When an input capture event occurs, channel 1 is programmed to reset its counter value. The channel 1 counter contains the position value for the shaft.

Example: 54.7.5.6.1 Quadrature Count Mode with Index Input Example

```c
// (See Processor Expert PulseAccumulator bean.)
// This example uses TMR0 and TMR1 for counting states of a quadrature position encoder.
// Timer input 0 is used as the primary count source (PHASEA).
// Timer input 1 is used as the secondary count source (PHASEB).
// Timer input 2 is used as the index input source (INDEX).

void Pulse_Init(void)
{
    /* TMR0_CTRL: CM=0,PCS=0,SCS=1,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMR0_CTRL,0x0A0); /* Set up mode */
    /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
      Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
    setReg(TMR0_SCTRL,0x00);
    setReg(TMR0_CNTR,0x00);    /* Reset counter register */
    setReg(TMR0_LOAD,0x00);    /* Reset load register */
    setReg(TMR0_COMP1,0x00);   /* Set up compare 1 register */
    setReg(TMR0_COMP2,0x00);   /* Set up compare 2 register */
    /* TMR0_CSCCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
      TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
    setReg(TMR0_CSCCTRL,0x00);
    setRegBitGroup(TMR0_CTRL,CM,0x04); /* Run counter */
}
```
54.7.5.7 Signed-Count Mode

If CTRL[CM] is set to '101', the counter counts the primary clock source while the selected secondary source provides the selected count direction (up/down).

Example: 54.7.5.7.1 Signed Count Mode Example

```c
void Pulse_Init(void)
{
    /* TMR0_CTRL: CM=0,PCS=2,SCS=1,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMR0_CTRL,0x0480);             /* Set up mode */
    /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
    Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
    setReg(TMR0_SCTRL,0x1000);
    setReg(TMR0_CNTR,0x00);             /* Reset counter register */
    setReg(TMR0_LOAD,0x00);             /* Reset load register */
    setRegBitGroup(TMR0_CTRL,CM,0x05);  /* Run counter */
}
```

54.7.5.8 Triggered-Count Mode 1

If CSCTRL[TCl] is clear and CTRL[CM] is set to '110', the counter will begin counting the primary clock source after a positive transition (negative edge if SCTRL[IPS]=1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. If a second input transition occurs before a terminal count is reached, counting will stop and SCTRL[TCF] (timer compare flag) will be set. Subsequent secondary input transitions will continue to restart and stop the counting until a compare event occurs.
Figure 54-4. Triggered Count Mode 1 (CTRL[LENGTH]=0)

Example: 54.7.5.8.1  Triggered Count Mode 1 Example

```
// (See Processor Expert PulseAccumulator bean.)
// This example uses TMR1 for triggered mode counting.
// Timer input 3 is used as the primary count source.
// Timer input 2 is used for the trigger input.

void Pulse_Init(void)
{
    /* TMR1_CTRL: CM=0,PCS=3,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMR1_CTRL,0x0700);            /* Set up mode */
    /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
       Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,OEN=0 */
    setReg(TMR1_SCTRL,0x1000);
    setReg(TMR1_CNTR,0x00);              /* Reset counter register */
    setReg(TMR1_LOAD,0x00);              /* Reset load register */
    setReg(TMR1_COMP1,0x0012);            /* Set up compare 1 register */
    /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,UP=0,OFLAG=0,
       TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
    setReg(TMR1_CSCTRL,0x00);            /* Set up compare 1 register */
    setRegBitGroup(TMR1_CTRL,CM,0x06);    /* Run counter */
}
```

54.7.5.9  Triggered-Count Mode 2

If CSCTRL[TCI] is set and CTRL[CM] is set to '110', the counter will begin counting the primary clock source after a positive transition (negative edge if SCTRL[IPS]=1) of the secondary input occurs. The counting will continue until a compare event occurs or another positive input transition is detected. If a second input transition occurs before a terminal count was reached, the counter will reload and continue counting. When CSCTRL[TCI] is set, the OFLAG output mode, CTRL[OUTMODE], should probably be set to '101' (cleared on init, set on compare) to ensure the output will be in a known state after the second input transition and subsequent reload takes place.
Example: 54.7.5.9.1  Triggered Count Mode 2

```c
// (See Processor Expert PulseAccumulator bean.)
// This example uses TMR1 for triggered mode counting.
// Timer input 3 is used as the primary count source.
// Timer input 2 is used for the trigger input.

void Pulse_Init(void)
{
    /* TMR1_CTRL: CM=0,PCS=3,SCS=2,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=0 */
    setReg(TMR1_CTRL,0x0700);           /* Set up mode */
    /* TMR1_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=1,IEF=0,IEFIE=0,IPS=0,INPUT=0,
        Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,FORCE=0,OPS=0,CEN=0 */
    setReg(TMR1_SCTRL,0x1000);

    setReg(TMR1_CNTR,0x00);             /* Reset counter register */
    setReg(TMR1_LOAD,0x00);             /* Reset load register */
    setReg(TMR1_COMP1,0x0012);           /* Set up compare 1 register */
    /* TMR1_CSCTRL: DBG_EN=0,FAULT=0,ALT_LOAD=0,ROC=0,TCI=0,OFLAG=0,
        TCF2EN=0,TCF1EN=0,TCF2=0,TCF1=0,CL2=0,CL1=0 */
    setReg(TMR1_CSCTRL,0x00);

    setRegBitGroup(TMR1_CTRL,CM,0x06); /* Run counter */
}
```

54.7.5.10  One-Shot Mode

If CTRL[CM] is set to '110', and the counter is set to reinitialize at a compare event (CTRL[LENGTH]=1), and CTRL[OUTMODE] is set to '101' (cleared on init, set on compare), the counter works in a one-shot mode. An external event causes the counter to count, and when the terminal count is reached, the output is asserted. This delayed output can be used to provide timing delays.

```
<table>
<thead>
<tr>
<th>LOAD = 0, COMP1 = 4</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary</td>
</tr>
<tr>
<td>Secondary</td>
</tr>
<tr>
<td>Count</td>
</tr>
<tr>
<td>timer_out</td>
</tr>
</tbody>
</table>
```

Figure 54-6. One-Shot Mode (CTRL[LENGTH]=1)
Example: 54.7.5.10.1 One-Shot Mode Example

```c
// (See Processor Expert PulseAccumulator bean.)
// This example uses TMR1 for one-shot mode counting.
// Timer input 3 is used as the primary count source.
// Timer input 2 is used for the trigger input.

void Pulse_Init(void)
{
    /* TMR1_CTRL: CM=0, PCS=3, SCS=2, ONCE=0, LENGTH=0, DIR=0, COINIT=0, OUTMODE=5 */
    setReg(TMR1_CTRL, 0x0725);           /* Set up mode */
    /* TMR1_SCTRL: TCF=0, TCFIE=0, TOF=0, TOFIE=1, IEF=0, IBFIE=0, IPS=0, INPUT=0,  
       Capture_Mode=0, MSTR=0, EEOF=0, VAL=0, FORCE=0, OPS=0, OEN=0 */ 
    setReg(TMR1_SCTRL, 0x1000);
    setReg(TMR1_CNTR, 0x00);             /* Reset counter register */
    setReg(TMR1_LOAD, 0x00);             /* Reset load register */
    setReg(TMR1_COMP1, 0x0004);           /* Set up compare 1 register */
    /* TMR1_CSCTRL: DBG_EN=0, FAULT=0, ALT_LOAD=0, ROC=0, TCI=0, UP=0, OFLAG=0,  
       TCF2EN=0, TCF1EN=0, CL2=0, CL1=0 */
    setReg(TMR1_CSCTRL, 0x00);
    setRegBitGroup(TMR1_CTRL, CM, 0x06);  /* Run counter */
}
```

54.7.5.11 Cascade-Count Mode

If CTRL[CM] is set to '111', the counter's input is connected to the output of another selected counter. The counter will count up and down as compare events occur in the selected source counter. This cascade or daisy-chained mode enables multiple counters to be cascaded to yield longer counter lengths. When operating in cascade mode, a special high-speed signal path is used between modules rather than the OFLAG output signal. If the selected source counter is counting up and it experiences a compare event, the counter will be incremented. If the selected source counter is counting down and it experiences a compare event, the counter will be decremented.

Up to four counters may be cascaded to create a 64-bit wide synchronous counter. Check the data sheet to see if there are any frequency limits for cascaded counting mode.

Whenever any counter is read within a counter module, all of the counters' values within the module are captured in their respective hold registers. This action supports the reading of a cascaded counter chain. First read any counter of a cascaded counter chain, then read the hold registers of the other counters in the chain. The cascaded counter mode is synchronous.
Note

It is possible to connect counters together by using the other (non-cascade) counter modes and selecting the outputs of other counters as a clock source. In this case, the counters are operating in a ripple mode, where higher order counters will transition a clock later than a purely synchronous design.

Example: 54.7.5.11.1 Generate Periodic Interrupt Cascading Two Counters

```c
void TimerInt_Init(void)
{
    // To do this, counter 2 is used to count 60,000 IP_bus clocks, which means it will compare and reload every 0.001 seconds.
    // Counter 3 is cascaded and used to count the 0.001 second ticks and generate the desired interrupt interval.

    // Set counter 2 to count IP_bus clocks
    setReg(TMR2_CTRL,0x1010);       /* Stop all functions of the timer */
    setReg(TMR3_CTRL,0x4010);       /* Set up cascade counter mode */
    setReg(TMR3_SCTRL,0x00);        /* Set up cascade counter mode */
    setReg(TMR2_SCTRL,0x00);        /* Set up cascade counter mode */

    /* Set counter 3 as cascaded and to count counter 2 outputs */
    setReg(TMR3_CNTR,0x00);         /* Reset counter register */
    setReg(TMR2_CNTR,0x00);         /* Reset load register */
    setReg(TMR3_LOAD,0x00);         /* Reset load register */
    setReg(TMR2_LOAD,0x00);         /* Reset load register */
    setReg(TMR3_CMP1,30000);        /* milliseconds in 30 seconds */
    setReg(TMR2_CMP1,60000);        /* milliseconds in 30 seconds */
    setReg(TMR3_CMP1,60000);        /* milliseconds in 30 seconds */

    /* Set to cycle every milisecond */
    setReg(TMR3_CSCTRL,0x00);       /* Enable compare 1 interrupt and */
    setReg(TMR3_CSCTRL,0x00);       /* compare 1 preload */
    setReg(TMR2_CSCTRL,0x00);       /* Enable compare 1 preload */
    setRegBitGroup(TMR2_CTRL,CM,0x01); /* Run counter */
}```
54.7.5.12 Pulse-Output Mode

If CTRL[CM]=001, and CTRL[OUTMODE] is set to 111’ (gated clock output), and CTRL[ONCE] is set, then the counter will output a pulse stream of pulses that has the same frequency of the selected clock source, and the number of output pulses is equal to the compare value minus the init value. This mode is useful for driving step motor systems.

Note

This does not work if CTRL[PCS] is set to 1000 (IP_bus/1).

Example: 54.7.5.12.1 Pulse Outputs Using Two Counters

```c
// (See Processor Expert PulseStream bean.)
// This example generates six 10ms pulses, from QT1 output.
// Assuming the chip is operating at 60 MHz.
// To do this, timer 3 is used to generate a clock with a period of 10ms.
// Timer 1 is used to gate these clocks and count the number of pulses that have been generated.

void PulseStream_Init(void)
{
    // Select IP_bus_clk/16 as the clock source for Timer 3
    /* TMR3_CTRL: CM=0, PCS=0x0C, SCS=0, ONCE=0, LENGTH=1, DIR=0, COINIT=0, OUTMODE=3 */
    setReg(TMR3_CTRL, 0x1823); /* Set up mode */
    /* TMR3_SCTRL: TCF=0, TCFIE=0, TOF=0, TOFIE=0, IEF=0, IEFIE=0, IPS=0, INPUT=0,
     Capture_Mode=0, MSTR=0, EOF=0, VAL=0, FORCE=0, OPS=0, OEN=0 */
    setReg(TMR3_SCTRL, 0x00);
    setReg(TMR3_LOAD, 0x00); /* Reset load register */
    setReg(TMR3_COMP1, 37500); /* (16 * 37500 ) / 60e6 = 0.01 sec */
    /* TMR3_CCTRL: DBG_EN=0, FAULT=0, ALT_LOAD=0, ROC=0, TCI=0, UP=0, OFLAG=0,
     TCF2EN=0, TCF1EN=0, TCF2=0, TCF1=0, CL2=0, CL1=0 */
    setReg(TMR3_CCTRL, 0x00); /* Set up comparator control register */

    // Timer 3 output is the clock source for this timer.
    /* TMR1_CTRL: CM=0, PCS=7, SCS=0, ONCE=1, LENGTH=1, DIR=0, COINIT=0, OUTMODE=7 */
    setReg(TMR1_CTRL, 0x0E67); /* Set up mode */
    /* TMR1_SCTRL: TCF=0, TCFIE=0, TOF=0, TOFIE=0, IEF=0, IEFIE=0, IPS=0, INPUT=0,
     Capture_Mode=0, MSTR=0, EOF=0, VAL=0, FORCE=0, OPS=0, OEN=1 */
}
```
54.7.5.13 Fixed-Frequency PWM Mode

If CTRL[CM]=001, count through roll-over (CTRL[LENGTH]=0), continuous count (CTRL[ONCE]=0) and CTRL[OUTMODE] is '110' (set on compare, cleared on counter roll-over), then the counter output yields a pulse-width modulated (PWM) signal with a frequency equal to the count clock frequency divided by 65,536 and a pulse-width duty cycle equal to the compare value divided by 65,536. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters.

Example: 54.7.5.13.1 Fixed-Frequency PWM Mode Example

```c
void PWM1_Init(void)
{
    (See Processor Expert PWM bean.)
    // This example uses TMR0 for Fixed-Frequency PWM mode timing.
    // The timer will count IP_bus clocks continuously until it rolls over.
    // This results in a PWM period of 65536 / 60e6 = 1092.267 usec
    // Initially, an output pulse width of 25 usec is generated ( 1500 / 60e6 )
    // giving a PWM ratio of 1500 / 65536 = 2.289%
    // This pulse width can be changed by changing the COMP1 register value (using CMPLD1).
    //
    setReg(TMR0_CNTR,0);        /* Reset counter */
    /* TMR0_SCTRL: TCF=0,TCFIE=0,TOF=0,TOFIE=0,IEF=0,IEFIE=0,IPS=0,INPUT=0,
       Capture_Mode=0,MSTR=0,EEOF=0,VAL=0,PORCE=1,OPS=0,OEN=1 */
    setReg(TMR0_SCTRL,0x05);    /* Enable output */
    setReg(TMR0_COMP1,1500);    /* Store initial value to the duty-compare register */
    /* TMR0_CTRL: CM=1,PCS=8,SCS=0,ONCE=0,LENGTH=0,DIR=0,COINIT=0,OUTMODE=6 */
    setReg(TMR0_CTRL,0x0306);   /* Run counter */
}
54.7.5.14 Variable-Frequency PWM Mode

If CTRL[CM]=001, count until compare (CTRL[LENGTH]=1), continuous count (CTRL[ONCE] = 0) and CTRL[OUTMODE] is '100' (toggle OFLAG and alternate compare registers), then the counter output yields a pulse-width modulated (PWM) signal whose frequency and pulse width is determined by the values programmed into the COMP1 and COMP2 registers, and the input clock frequency. This method of PWM generation has the advantage of allowing almost any desired PWM frequency and/or constant on or off periods. This mode of operation is often used to drive PWM amplifiers used to power motors and inverters. The CMPLD1 and CMPLD2 registers are especially useful for this mode, as they allow the programmer time to calculate values for the next PWM cycle while the PWM current cycle is underway.

To set up the TMR to run in variable frequency PWM mode with compare preload please use the following setup for the specific counter you would like to use. When performing the setup, update the TMR_CTRL register last because the counter will start counting if the count mode is changed to any value other than 000 (assuming the primary count source is already active).

**Timer Control Register (CTRL)**

- CM=001 (count rising edges of primary source)
- PCS=1000 (IP bus clock for best granularity for waveform timing)
- SCS=Any (ignored in this mode)
- ONCE=0 (want to count repeatedly)
- LENGTH=1 (want to count until compare value is reached and re-initialize counter register)
- DIR=Any (user's choice. The compare register values must be chosen carefully to account for things like roll-under, etc.)
- COINIT=0 (user can set this if they need this function)
- OUTMODE=100 (toggle OFLAG output using alternating compare registers)

**Timer Status and Control Register (SCTRL)**

- OEN = 1 (output enable to allow OFLAG output to be put on an external pin. Set this bit as needed.)
• OPS = Any (user's choice)

• Make sure the rest of the bits are cleared for this register. We will enable interrupts in the comparator status and control register instead of in this register.

Comparator Status and Control Register (CSCTRL)

• TCF2EN=1 (allow interrupt to be issued when CSCTRL[TCF2] is set)
• TCF1EN=0 (do not allow interrupt to be issued when CSCTRL[TCF1] is set)
• TCF1=0 (clear timer compare 1 interrupt source flag. This is set when counter register equals compare register 1 value and OFLAG is low)
• TCF2=0 (clear timer compare 2 interrupt source flag. This is set when counter register equals compare register 2 value and OFLAG is high)
• CL1=10 (load compare register when CSCTRL[TCF2] is asserted)
• CL2=01 (load compare register when CSCTRL[TCF1] is asserted)

Interrupt Service Routines

To service the CSCTRL[TCF2] interrupts generated by the timer, the interrupt controller must be configured to enable the interrupts for the particular timer being used. Additionally the user will need to write an interrupt service routine to do at a minimum the following:

• Clear CSCTRL[TCF2] and CSCTRL[TCF1] flags.
• Calculate and write new values for both CMPLD1 and CMPLD2.

Timing

This figure contains the timing for using the compare preload feature. The compare preload cycle begins with a compare event on COMP2 causing CSCTRL[TCF2] to be asserted. COMP1 is loaded with the value in the CMPLD1 (c3) one IP bus clock later. In addition an interrupt is asserted by the timer and the interrupt service routine is executed during which both comparator load registers are updated with new values (c4 and c5). When CSCTRL[TCF1] is asserted, COMP2 is loaded with the value in CMPLD2 (c4). And on the subsequent CSCTRL[TCF2] event, COMP1 is loaded with the value in CMPLD1 (c5). The cycle starts over again as an interrupt is asserted and the interrupt service routine clears CSCTRL[TCF1] and CSCTRL[TCF2] and calculates new values for CMPLD1 and CMPLD2.
Step 1-- CNTR matches COMP2 value. CSCTRL[TCF2] is asserted and an interrupt request is generated.

Step 2-- One clock later, OFLAG toggles, CMPLD1 is copied to COMP1, LOAD is copied to CNTR, the counter starts counting.

Step 3-- The interrupt service routine clears CSCTRL[TCF1] and CSCTRL[TCF2] and the ISR loads CMPLD1 and CMPLD2 with the values for the next cycle. The counter continues counting until CNTR matches COMP1.

Step 4-- CSCTRL[TCF1] is asserted. One clock later, OFLAG toggles, CMPLD2 is copied to COMP2, LOAD is copied to CNTR and the counter starts counting.

Step 5-- The counter continues counting until CNTR matches COMP2.

Figure 54-8. Compare Load Timing

Example: 54.7.5.14.1 Variable Frequency PWM Mode

```c
void PPG1_Init(void)
{
    setReg(TMR0_LOAD,0); /* Clear load register */
}```
54.8 Resets

54.8.1 General

The TMR module can be reset only by the RST_B signal. This forces all registers to their reset state and clears the OFLAG signal if it is asserted. The counter will be turned off until the settings in the control register are changed.

### 54.10.2 Description of Interrupt Operation

#### 54.10.2.1 Timer Compare Interrupts

These interrupts are generated when a successful compare occurs between a counter and its compare registers while SCTRL[TCFIE] is set. These interrupts are cleared by writing a zero to the appropriate SCTRL[TCF].

When a timer compare interrupt is set in TMR_SCTRL and the Compare Load registers are available, one of the following two interrupts will also be asserted.
54.10.2.1.1 Timer Compare 1 Interrupts (Available with Compare Load Feature)

These interrupts are generated when a successful compare occurs between a counter and its COMP1 register while CSCTRL[TCF1EN] is set. These interrupts are cleared by writing a zero to the appropriate CSCTRL[TCF1].

54.10.2.1.2 Timer Compare 2 Interrupts (Available with Compare Load Feature)

These interrupts are generated when a successful compare occurs between a counter and its COMP2 register while CSCTRL[TCF2EN] is set. These interrupts are cleared by writing a zero to the appropriate CSCTRL[TCF2].

54.10.2.2 Timer Overflow Interrupts

These interrupts are generated when a counter rolls over its maximum value while SCTRL[TOFIE] is set. These interrupts are cleared by writing zero to the appropriate SCTRL[TOF].

54.10.2.3 Timer Input Edge Interrupts

These interrupts are generated by a transition of the input signal (either positive or negative depending on IPS setting) while SCTRL[IEFIE] is set. These interrupts are cleared by writing a zero to the appropriate SCTRL[IEF].

54.11 DMA

The TMR module can generate twelve DMA requests: three for each of the four counters/channels. Refer to the following table.

NOTE
In this device, PWMx_EXTB is not applicable. It also does not support external ADC input. Also there is No NanoEdge placement block in this device.

55.2 Introduction

The pulse width modulator (PWM) module contains PWM submodules, each of which is set up to control a single half-bridge power stage. Fault channel support is provided.

This PWM module can generate various switching patterns, including highly sophisticated waveforms. It can be used to control all known motor types and is ideal for controlling different Switched Mode Power Supplies (SMPS) topologies as well.
55.2.1 Features

- 16 bits of resolution for center, edge-aligned, and asymmetrical PWMs
- Fractional PWM clock generation for enhanced resolution of the PWM period and duty cycle
- Dithering to simulate enhanced resolution when fine edge placement is not available
- PWM outputs that can operate as complementary pairs or independent channels
- Ability to accept signed numbers for PWM generation
- Independent control of both edges of each PWM output
- Support for synchronization to external hardware or other PWM
- Double buffered PWM registers
  - Integral reload rates from 1 to 16
  - Half cycle reload capability
- Multiple output trigger events can be generated per PWM cycle via hardware
- Support for double switching PWM outputs
- Fault inputs can be assigned to control multiple PWM outputs
- Programmable filters for fault inputs
- Independently programmable PWM output polarity
- Independent top and bottom deadtime insertion
- Each complementary pair can operate with its own PWM frequency and deadtime values
- Individual software control for each PWM output
- All outputs can be programmed to change simultaneously via a FORCE_OUT event
- PWM_X pin can optionally output a third PWM signal from each submodule
- Channels not used for PWM generation can be used for buffered output compare functions
- Channels not used for PWM generation can be used for input capture functions
- Enhanced dual edge capture functionality
- The option to supply the source for each complementary PWM signal pair from any of the following:
  - Crossbar module outputs
  - External ADC input, taking into account values set in ADC high and low limit registers

55.2.2 Modes of Operation

Be careful when using this module in stop, wait and debug operating modes.

CAUTION

Some applications (such as three-phase AC motors) require regular software updates for proper operation. Failure to
provide regular software updates could result in destroying the hardware setup.

To accommodate this situation, PWM outputs are placed in their inactive states in stop mode, and they can optionally be placed in inactive states in wait and debug (EOnCE) modes. PWM outputs are reactivated (assuming they were active beforehand) when these modes are exited.

**Table 55-2. Modes when PWM Operation is Restricted**

### 55.2.3 Block Diagram

The following figure is a block diagram of the PWM.
55.3 Signal Descriptions

The PWM has pins named PWM[n]_A, PWM[n]_B, PWM[n]_X, FAULT[n], PWM[n]_EXT_SYNC, EXT_FORCE, PWM[n]_EXTA, and PWM[n]_EXTB. The PWM also has an on-chip input called EXT_CLK and output signals called PWM[n]_OUT_TRIGx.

55.3.1 PWM[n]_A and PWM[n]_B - External PWM Output Pair

These pins are the output pins of the PWM channels. These pins can be independent PWM signals or a complementary pair. When not needed as an output, they can be used as inputs to the input capture circuitry.
55.3.2 PWM[n]_X - Auxiliary PWM Output signal

These pins are the auxiliary output pins of the PWM channels. They can be independent PWM signals. When not needed as an output, they can be used as inputs to the input capture circuitry or used to detect the polarity of the current flowing through the complementary circuit at deadtime correction.

55.3.3 FAULT[n] - Fault Inputs

These are input pins for disabling selected PWM outputs.

55.3.4 PWM[n]_EXT_SYNC - External Synchronization Signal

These input signals allow a source external to the PWM to initialize the PWM counter. In this manner, the PWM can be synchronized to external circuitry.

55.3.5 EXT_FORCE - External Output Force Signal

This input signal allows a source external to the PWM to force an update of the PWM outputs. In this manner, the PWM can be synchronized to external circuitry.

55.3.6 PWM[n]_EXTA and PWM[n]_EXTB - Alternate PWM Control Signals

These pins allow an alternate source to control the PWM_A and PWM_B outputs. Typically, either the PWM_EXTA or PWM_EXTB input (depending on the state of MCTRL/IPOL) is used for the generation of a complementary pair. Typical control signals include ADC conversion high/low limits, TMR outputs, GPIO inputs, and comparator outputs.

55.3.7 PWM[n]_OUT_TRIG0 and PWM[n]_OUT_TRIG1 - Output Triggers

These outputs allow the PWM submodules to control timing of ADC conversions. See the description of the Output Trigger Control Register for information about how to enable these outputs and how the compare registers match up to the output triggers.
55.3.8 EXT_CLK - External Clock Signal

This signal allows a source external to the PWM (typically a timer or an off-chip source) to control the PWM clocking. In this manner, the PWM can be synchronized to the timer, or multiple chips can be synchronized to each other.

55.4 Functional Description

55.4.1 PWM Capabilities

This section describes some capabilities of the PWM module.

55.4.1.1 Center Aligned PWMs

Each submodule has its own timer that is capable of generating PWM signals on two output pins. The edges of each of these signals are controlled independently as shown in Figure 55-2.
The submodule timers only count in the up direction and then reset to the INIT value. Instead of having a single value that determines pulse width, there are two values that must be specified: the turn on edge and the turn off edge. This double action edge generation not only gives the user control over the pulse width, but over the relative alignment of the signal as well. As a result, there is no need to support separate PWM alignment modes since the PWM alignment mode is inherently a function of the turn on and turn off edge values.

Figure 55-2 also illustrates an additional enhancement to the PWM generation process. When the counter resets, it is reloaded with a user specified value, which may or may not be zero. If the value chosen happens to be the 2's complement of the modulus value, then the PWM generator operates in "signed" mode. This means that if each PWM's turn on and turn off edge values are also the same number but only different in their sign, the "on" portion of the output signal will be centered around a count value of zero. Therefore, only one PWM value needs to be calculated in software and then this value and its negative are provided to the submodule as the turn off and turn on edges respectively. This technique will result in a pulse width that always consists of an odd number of timer counts. If all PWM signal edge calculations follow this same convention, then the signals will be center aligned with respect to each other, which is the goal. Of course, center
alignment between the signals is not restricted to symmetry around the zero count value, as any other number would also work. However, centering on zero provides the greatest range in signed mode and also simplifies the calculations.

### 55.4.1.2 Edge Aligned PWMs

When the turn on edge for each pulse is specified to be the INIT value, then edge aligned operation results, as the following figure shows. Therefore, only the turn off edge value needs to be periodically updated to change the pulse width.

With edge aligned PWMs, another example of the benefits of signed mode can be seen. A common way to drive an H-bridge is to use a technique called "bipolar" PWMs where a 50% duty cycle results in zero volts on the load. Duty cycles less than 50% result in negative load voltages and duty cycles greater than 50% generate positive load voltages. If the module is set to signed mode operation (the INIT and VAL1 values are the same number with opposite signs), then there is a direct proportionality between the PWM turn off edge value and the motor inverter voltage, INCLUDING the sign. So once again, signed mode of operation simplifies the software interface to the PWM module since no offset calculations are required to translate the output variable control algorithm to the voltage on an H-Bridge load.
55.4.1.3 Phase Shifted PWMs

In the previous sections, the benefits of signed mode of operation were discussed in the context of simplifying the required software calculations by eliminating the requirement to bias up signed variables before applying them to the module. However, if numerical biases are applied to the turn on and turn off edges of different PWM signal, the signals will be phase shifted with respect to each other, as the following figure shows. This results in certain advantages when applied to a power stage. For example, when operating a multi-phase inverter at a low modulation index, all of the PWM switching edges from the different phases occur at nearly the same time. This can be troublesome from a noise standpoint, especially if ADC readings of the inverter must be scheduled near those times. Phase shifting the PWM signals can open up timing windows between the switching edges to allow a signal to be sampled by the ADC. However, phase shifting does NOT affect the duty cycle so average load voltage is not affected.

![Phase Shifted Outputs Example](image)

An additional benefit of phase shifted PWMs appears in Figure 55-5. In this case, an H-Bridge circuit is driven by 4 PWM signals to control the voltage waveform on the primary of a transformer. Both left and right side PWMs are configured to always generate a square wave with 50% duty cycle. This works out nicely for the H-Bridge since no narrow pulse widths are generated reducing the high frequency switching
requirements of the transistors. Notice that the square wave on the right side of the H-Bridge is phase shifted compared to the left side of the H-Bridge. As a result, the transformer primary sees the bottom waveform across its terminals. The RMS value of this waveform is directly controlled by the amount of phase shift of the square waves. Regardless of the phase shift, no DC component appears in the load voltage as long as the duty cycle of each square wave remains at 50% making this technique ideally suited for transformer loads. As a result, this topology is frequently used in industrial welders to adjust the amount of energy delivered to the weld arc.

Figure 55-5. Phase Shifted PWMs Applied to a Transformer Primary
55.4.1.4 Double Switching PWMs

Double switching PWM output is supported to aid in single shunt current measurement and three phase reconstruction. This method support two independent rising edges and two independent falling edges per PWM cycle. The VAL2 and VAL3 registers are used to generate the even channel (labelled as PWM_A in the figure) while VAL4 and VAL5 are used to generate the odd channel. The two channels are combined using XOR logic (force out logic) as the following figure shows. The DBLPWM signal can be run through the deadtime insertion logic.

Figure 55-6. Double Switching Output Example
55.4.1.5 ADC Triggering

In cases where the timing of the ADC triggering is critical, it must be scheduled as a hardware event instead of software activated. With this PWM module, multiple ADC triggers can be generated in hardware per PWM cycle without the requirement of another timer module. Figure 55-7 shows how this is accomplished. When specifying complementary mode of operation, only two edge comparators are required to generate the output PWM signals for a given submodule. This means that the other comparators are free to perform other functions. In this example, the software does not need to quickly respond after the first conversion to set up other conversions that must occur in the same PWM cycle.

![Figure 55-7. Multiple Output Trigger Generation in Hardware](image)

Because each submodule has its own timer, it is possible for each submodule to run at a different frequency. One of the options possible with this PWM module is to have one or more submodules running at a lower frequency, but still synchronized to the timer in submodule0. Figure 55-8 shows how this feature can be used to schedule ADC triggers over multiple PWM cycles. A suggested use for this configuration would be to use the lower-frequency submodule to control the sampling frequency of the software control algorithm where multiple ADC triggers can now be scheduled over the entire sampling period. In Figure 55-8, all submodule comparators are shown being used for ADC trigger generation.
**55.4.1.6 Enhanced Capture Capabilities (E-Capture)**

When a PWM pin is not being used for PWM generation, it can be used to perform input captures. Recall that for PWM generation BOTH edges of the PWM signal are specified via separate compare register values. When programmed for input capture, both of these registers work on the same pin to capture multiple edges, toggling from one to the other in either a free running or one-shot fashion. By simply programming the desired edge of each capture circuit, period and pulse width of an input signal can easily be measured without the requirement to re-arm the circuit. In addition, each edge of the input signal can clock an 8 bit counter where the counter output is compared to a user specified value (EDGCMP). When the counter output equals EDGCMP, the value of the submodule timer is captured and the counter is automatically reset. This feature allows the module to count a specified number of edge events and then perform a capture and interrupt. The following figure illustrates some of the functionality of the E-Capture circuit.
When a submodule is being used for PWM generation, its timer counts up to the modulus value used to specify the PWM frequency and then is re-initialized. Therefore, using this timer for input captures on one of the other pins (for example, PWM_X) has limited utility since it does not count through all of the numbers and the timer reset represents a discontinuity in the 16 bit number range. However, when measuring a signal that is synchronous to the PWM frequency, the timer modulus range is perfectly suited for the application. Consider the following figure as an example. In this application the output of a PWM power stage is connected to the PWM_X pin that is configured for free running input captures. Specifically, the CVAL0 capture circuitry is programmed for rising edges and the CVAL1 capture circuitry is set for falling edges. This will result in new load pulse width data being acquired every PWM cycle. To calculate the pulse width, simply subtract the CVAL0 register value from the CVAL1 register value. This measurement is extremely beneficial when performing dead-time distortion correction on a half bridge circuit driving an inductive load. Also, these values can be directly compared to the VALx registers responsible for generating the PWM outputs to obtain a measurement of system propagation delays. For details, refer to the separate discussion of deadtime distortion correction.
During deadtime, load inductance drives voltage with polarity that keeps inductive current flowing through diodes.

**Figure 55-10. Output Pulse Width Measurement Possible with the E-Capture Circuit**

### 55.4.1.7 Synchronous Switching of Multiple Outputs

Before the PWM signals are routed to the output pins, they are processed by a hardware block that permits all submodule outputs to be switched synchronously. This feature can be extremely useful in commutated motor applications where the next commutation state can be laid in ahead of time and then immediately switched to the outputs when the appropriate condition or time is reached. Not only do all the changes occur synchronously on all submodule outputs, but they occur IMMEDIATELY after the trigger event occurs eliminating any interrupt latency.

The synchronous output switching is accomplished via a signal called FORCE_OUT. This signal originates from the local FORCE bit within the submodule, from submodule0, or from external to the PWM module and, in most cases, is supplied from an external timer channel configured for output compare. In a typical application, software sets up the desired states of the output pins in preparation for the next FORCE_OUT event. This selection lays dormant until the FORCE_OUT signal transitions and then all outputs are
switched simultaneously. The signal switching is performed upstream from the deadtime generator so that any abrupt changes that might occur do not violate deadtime on the power stage when in complementary mode.

Figure 55-11 shows a popular application that can benefit from this feature. On a brushless DC motor it is desirable on many cases to spin the motor without need of hall-effect sensor feedback. Instead, the back EMF of the motor phases is monitored and this information is used to schedule the next commutation event. The top waveforms of Figure 55-11 are a simplistic representation of these back EMF signals. Timer compare events (represented by the long vertical lines in the diagram) are scheduled based on the zero crossings of the back-EMF waveforms. The PWM module is configured via software ahead of time with the next state of the PWM pins in anticipation of the compare event. When it happens, the output compare of the timer drives the FORCE_OUT signal which immediately changes the state of the PWM pins to the next commutation state with no software latency.
55.4.2 Functional Details

This section describes the implementation of various sections of the PWM in greater detail.

The following figure is a high-level block diagram of output PWM generation.

![Figure 55-11. Sensorless BLDC Commutation Using the Force Out Function](image-url)
55.4.2.1 PWM Clocking

Figure 55-13 shows the logic used to generate the main counter clock. Each submodule can select between three clock signals: the IPBus clock, EXT_CLK, and AUX_CLK. The EXT_CLK goes to all of the submodules. The AUX_CLK signal is broadcast from submodule0 and can be selected as the clock source by other submodules so that the 8-bit prescaler and MCTRL[RUN] from submodule0 can control all of the submodules.

To permit lower PWM frequencies, the prescaler produces the PWM clock frequency by dividing the IPBus clock frequency by 1-128. The prescaler bits, CTRL[PRSC], select the prescaler divisor. This prescaler is buffered and will not be used by the PWM generator until MCTRL[LDOK] is set and a new PWM reload cycle begins or CTRL[LDMOD] is set.
55.4.2.2 Register Reload Logic

The register reload logic is used to determine when the outer set of registers for all double buffered register pairs will be transferred to the inner set of registers. The register reload event can be scheduled to occur every "n" PWM cycles using CTRL[LDFQ] and CTRL[FULL]. A half cycle reload option is also supported (CTRL[HALF]) where the reload can take place in the middle of a PWM cycle. The half cycle point is defined by the VAL0 register and does not have to be exactly in the middle of the PWM cycle.

As illustrated in Figure 55-14 the reload signal from submodule0 can be broadcast as the Master Reload signal allowing the reload logic from submodule0 to control the reload of registers in other submodules.

![](image)

**Figure 55-14. Register Reload Logic**

55.4.2.3 Counter Synchronization

In the following figure, the 16 bit counter will count up until its output equals VAL1 which is used to specify the counter modulus value. The resulting compare causes a rising edge to occur on the Local Sync signal which is one of four possible sources used to cause the 16 bit counter to be initialized with INIT. If Local Sync is selected as the counter initialization signal, then VAL1 within the submodule effectively controls the timer period (and thus the PWM frequency generated by that submodule) and everything works on a local level.
The Master Sync signal originates as the Local Sync from submodule0. If configured to do so, the timer period of any submodule can be locked to the period of the timer in submodule0.

The PWM_EXT_SYNC signal originates on chip or off chip depending on the system architecture. This signal may be selected as the source for counter initialization so that an external source can control the period of all submodules.

If the Master Reload signal is selected as the source for counter initialization, then the period of the counter will be locked to the register reload frequency of submodule0. Since the reload frequency is usually commensurate to the sampling frequency of the software control algorithm, the submodule counter period will therefore equal the sampling period. As a result, this timer can be used to generate output compares or output triggers over the entire sampling period which may consist of several PWM cycles. The Master Reload signal can only originate from submodule0.

The counter can optionally initialize upon the assertion of the FORCE_OUT signal assuming that CTRL2[FRCEN] is set. As indicated by the preceding figure, this constitutes a second init input into the counter which will cause the counter to initialize regardless of which signal is selected as the counter init signal. The FORCE_OUT signal is provided mainly for commutated applications. When PWM signals are commutated on an inverter controlling a brushless DC motor, it is necessary to restart the PWM cycle at the beginning of the commutation interval. This action effectively resynchronizes the PWM waveform to the commutation timing. Otherwise, the average voltage applied to a motor winding integrated over the entire commutation interval will be a function of the
timing between the asynchronous commutation event with respect to the PWM cycle. The effect is more critical at higher motor speeds where each commutation interval may consist of only a few PWM cycles. If the counter is not initialized at the start of each commutation interval, the result will be an oscillation caused by the beating between the PWM frequency and the commutation frequency.

55.4.2.4 PWM Generation

Figure 55-16 illustrates how PWM generation is accomplished in each submodule. In each case, two comparators and associated VALx registers are utilized for each PWM output signal. One comparator and VALx register are used to control the turn-on edge, while a second comparator and VALx register control the turn-off edge.

Figure 55-16. PWM Generation Hardware
The generation of the Local Sync signal is performed exactly the same way as the other PWM signals in the submodule. While comparator 0 causes a falling edge of the Local Sync signal, comparator 1 generates a rising edge. Comparator 1 is also hardwired to the reload logic to generate the full cycle reload indicator.

If VAL1 is controlling the modulus of the counter and VAL0 is half of the VAL1 register minus the INIT value, then the half cycle reload pulse will occur exactly half way through the timer count period and the Local Sync will have a 50% duty cycle. On the other hand, if the VAL1 and VAL0 registers are not required for register reloading or counter initialization, they can be used to modulate the duty cycle of the Local Sync signal, effectively turning it into an auxiliary PWM signal (PWM_X) assuming that the PWM_X pin is not being used for another function such as input capture or deadtime distortion correction. Including the Local Sync signal, each submodule is capable of generating three PWM signals where software has complete control over each edge of each of the signals.

If the comparators and edge value registers are not required for PWM generation, they can also be used for other functions such as output compares, generating output triggers, or generating interrupts at timed intervals.

The 16-bit comparators shown in Figure 55-16 are "equal to" comparators. In addition, if both the set and reset of the flip-flop are asserted, then the flop output goes to 0.

55.4.2.5 Output Compare Capabilities

By using the VALx registers in conjunction with the submodule timer and 16 bit comparators, buffered output compare functionality can be achieved with no additional hardware required. Specifically, the following output compare functions are possible:

- An output compare sets the output high
- An output compare sets the output low
- An output compare generates an interrupt
- An output compare generates an output trigger

In PWM generation, an output compare is initiated by programming a VALx register for a timer compare, which in turn causes the output of the D flip-flop to either set or reset. For example, if an output compare is desired on the PWM_A signal that sets it high, VAL2 would be programmed with the counter value where the output compare should take place. However, to prevent the D flip-flop from being reset again after the compare has occurred, the VAL3 register must be programmed to a value outside of the modulus range of the counter. Therefore, a compare that would result in resetting the D flip-flop
output would never occur. Conversely, if an output compare is desired on the PWM_A signal that sets it low, the VAL3 register is programmed with the appropriate count value and the VAL2 register is programmed with a value outside the counter modulus range. Regardless of whether a high compare or low compare is programmed, an interrupt or output trigger can be generated when the compare event occurs.

55.4.2.6 Force Out Logic

For each submodule, software can select between eight signal sources for the FORCE_OUT signal: local CTRL2[FORCE], the Master Force signal from submodule0, the local Reload signal, the Master Reload signal from submodule0, the Local Sync signal, the Master Sync signal from submodule0, the EXT_SYNC signal from on- or off-chip, or the EXT_FORCE signal from on- or off-chip depending on the chip architecture. The local signals are used when the user simply wants to change the signals on the output pins of the submodule without regard for synchronization with other submodules. However, if it is required that all signals on all submodule outputs change at the same time, the Master, EXT_SYNC, or EXT_FORCE signals should be selected.

Figure 55-17 illustrates the Force logic. The SEL23 and SEL45 fields each choose from one of four signals that can be supplied to the submodule outputs: the PWM signal, the inverted PWM signal, a binary level specified by software via the OUT23 and OUT45 bits, or the PWM_EXTA or PWM_EXTB alternate external control signals. The selection can be determined ahead of time and, when a FORCE_OUT event occurs, these values are presented to the signal selection mux that immediately switches the requested signal to the output of the mux for further processing downstream.
The local CTRL2[FORCE] signal of submodule0 can be broadcast as the Master Force signal to other submodules. This feature allows the CTRL2[FORCE] of submodule0 to synchronously update all of the submodule outputs at the same time. The EXT_FORCE signal originates from outside the PWM module from a source such as a timer or digital comparators in the Analog-to-Digital Converter.

55.4.2.7 Independent or Complementary Channel Operation

Writing a logic one to CTRL2[INDEP] configures the pair of PWM outputs as two independent PWM channels. Each PWM output is controlled by its own VALx pair operating independently of the other output.

Writing a logic zero to CTRL2[INDEP] configures the PWM output as a pair of complementary channels. The PWM pins are paired as shown in Figure 55-18 in complementary channel operation. Which signal is connected to the output pin (PWM23 or PWM45) is determined by MCTRL[IPOL].

Figure 55-17. Force Out Logic
Figure 55-18. Complementary Channel Pair

The complementary channel operation is for driving top and bottom transistors in a motor drive circuit, such as the one in Figure 55-19.

Figure 55-19. Typical 3 Phase AC Motor Drive

Complementary operation allows the use of the deadtime insertion feature.

55.4.2.8 Deadtime Insertion Logic

The following figure shows the deadtime insertion logic of each submodule which is used to create non-overlapping complementary signals when not in independent mode.
While in the complementary mode, a PWM pair can be used to drive top/bottom transistors, as shown in the figure. When the top PWM channel is active, the bottom PWM channel is inactive, and vice versa.

**Note**

To avoid short circuiting the DC bus and endangering the transistor, there must be no overlap of conducting intervals between top and bottom transistor. But the transistor's characteristics may make its switching-off time longer than switching-on time. To avoid the conducting overlap of top and bottom transistors, deadtime needs to be inserted in the switching period, as illustrated in the following figure.

The deadtime generators automatically insert software-selectable activation delays into the pair of PWM outputs. The deadtime registers (DTCNT0 and DTCNT1) specify the number of IPBus clock cycles to use for deadtime delay. Every time the deadtime generator inputs change state, deadtime is inserted. Deadtime forces both PWM outputs in the pair to the inactive state.
When deadtime is inserted in complementary PWM signals connected to an inverter driving an inductive load, the PWM waveform on the inverter output will have a different duty cycle than what appears on the output pins of the PWM module. This results in a distortion in the voltage applied to the load. A method of correcting this, adding to or subtracting from the PWM value used, is discussed next.

![Diagram of PWM signals with and without deadtime](image)

**Figure 55-21. Deadtime Insertion**

### 55.4.2.8.1 Top/Bottom Correction

In complementary mode, either the top or the bottom transistor controls the output voltage. However, deadtime has to be inserted to avoid overlap of conducting interval between the top and bottom transistor. Both transistors in complementary mode are off during deadtime, allowing the output voltage to be determined by the current status of load and introduce distortion in the output voltage. See the following figure. On AC induction motors running open-loop, the distortion typically manifests itself as poor low-speed performance, such as torque ripple and rough operation.
During deadtime, load inductance distorts output voltage by keeping current flowing through the diodes. This deadtime current flow creates a load voltage that varies with current direction. With a positive current flow, the load voltage during deadtime is equal to the bottom supply, putting the top transistor in control. With a negative current flow, the load voltage during deadtime is equal to the top supply putting the bottom transistor in control.

Remembering that the original PWM pulse widths where shortened by deadtime insertion, the averaged sinusoidal output will be less than the desired value. However, when deadtime is inserted, it creates a distortion in the motor current waveform inverter outputs. This distortion is aggravated by dissimilar turn-on and turn-off delays of each of the transistors. By giving the PWM module information on which transistor is controlling at a given time this distortion can be corrected.

For a typical circuit in complementary channel operation, only one of the transistors will be effective in controlling the output voltage at any given time. This depends on the direction of the motor inverter current for that pair, as the preceding figure shows. To correct distortion one of two different factors must be added to the desired PWM value, depending on whether the top or bottom transistor is controlling the output voltage. Therefore, the software is responsible for calculating both compensated PWM values prior to placing them in the VALx registers. Either the VAL2/VAL3 or the VAL4/VAL5 register pair controls the pulse width at any given time. For a given PWM pair, whether the VAL2/VAL3 or VAL4/VAL5 pair is active depends on either:

- The state of the current status pin, PWMX, for that driver
- The state of the odd/even correction bit, MCTRL[IPOL], for that driver
To correct deadtime distortion, software can decrease or increase the value in the appropriate VALx register.

- In edge-aligned operation, decreasing or increasing the PWM value by a correction value equal to the deadtime typically compensates for deadtime distortion.
- In center-aligned operation, decreasing or increasing the PWM value by a correction value equal to one-half the deadtime typically compensates for deadtime distortion.

### 55.4.2.8.2 Manual Correction

To detect the current status, the voltage on each PWMX pin is sampled twice in a PWM period, at the end of each deadtime. The value is stored in CTRL[DT]. CTRL[DT] is a timing marker especially indicating when to toggle between PWM value registers. Software can then set MCTRL[IPOL] to switch between VAL2/VAL3 and VAL4/VAL5 register pairs according to CTRL[DT] values.

![Figure 55-23. Current-status Sense Scheme for Deadtime Correction](image)

Both D flip-flops latch low, CTRL[DT] = 00, during deadtime periods if current is large and flowing out of the complementary circuit. See the preceding figure. Both D flip-flops latch the high, CTRL[DT] = 11, during deadtime periods if current is also large and flowing into the complementary circuit.

However, under low-current, the output voltage of the complementary circuit during deadtime is somewhere between the high and low levels. The current cannot free-wheel through the opposition anti-body diode, regardless of polarity, giving additional distortion when the current crosses zero. **Sampled results will be CTRL[DT] = b10. Thus, the best time to change one PWM value register to another is just before the current zero crossing.**
55.4.2.9 Fractional Delay Logic

For applications where more resolution than a single IPBus clock period is needed, the fractional delay logic can be used to achieve fine resolution on the rising and falling edges of the PWM_A and PWM_B outputs and fine resolution for the PWM period. Enable the use of the fractional delay logic by setting FRCTRL[FRACx_EN]. The FRACVALx registers act as a fractional clock cycle addition to the turn on and turn off count specified by the VAL2, VAL3, VAL4, or VAL5 registers. The FRACVAL1 register acts as a fractional increase in the PWM period as defined by VAL1. If FRACVAL1 is programmed to a non-zero value, then the largest value for the VAL1 register is 0xFFFFE for unsigned usage or 0x7FFE for signed usage. This limit is needed in order to avoid counter rollovers when accumulating the fractional additional period.

The results of the fractional delay logic depend on whether or not the PWM submodule has an analog NanoEdge placer block available.
55.4.2.9.1 Fractional Delay Logic with NanoEdge Placement Block

Using the NanoEdge placer block requires that the IPBus clock to the PWM be set at a defined frequency. The NanoEdge placer is powered up by setting FRCTRL[FRAC_PU]. Enable fine edge control on the various PWM edges by setting FRCTRL[FRACx_EN]. The fractional values in the FRACVALx registers allow placing the PWM edge or PWM period to a granularity of 1/32 of the IPBus clock period. For example, if you desire the rising edge of the PWMA output to occur at a count of 12.25, then program VAL2 with 0x000C and FRACVAL2 with 0x4000. Using FRACVAL1 will adjust the PWM period with the same granularity of 1/32 of a clock period.

If the FRCTRL[FRAC_PU] bits in all of the submodules are clear, then the NanoEdge placer is powered down, and alternate clock frequencies can be used without the NanoEdge placement feature.

55.4.2.9.2 Fractional Delay Logic without NanoEdge Placement Block

For submodules that are not supported by the NanoEdge placer, the PWM can use dithering to simulate fine edge control. Enable this feature by setting the FRCTRL[FRAC1_EN], FRCTRL[FRAC23_EN], and FRCTRL[FRAC45_EN] bits. It is unnecessary to set FRCTRL[FRAC_PU]. The PWM period or the PWM edges will dither from the nearest whole number values to achieve an average value that is equivalent to the programmed fractional value. The added cycles are based on the accumulation of the fractional component. For example, if you want the PWM period to be 50.25 clock cycles, then program VAL1 with 0x0032 and FRACVAL1 with 0x4000. The PWM period will be 50 cycles long most of the time, but will occasionally be 51 cycles long to achieve a long-term average of 50.25 cycles.

In submodules that are not supported by a NanoEdge placer, the clock frequency is not required to be any specific value to achieve proper operation.

55.4.2.10 Output Logic

The following figure shows the output logic of each submodule including how each PWM output has individual fault disabling, polarity control, and output enable. This allows for maximum flexibility when interfacing to the external circuitry.

The PWM23 and PWM45 signals which are output from the deadtime logic (refer to the figure) are positive true signals. In other words, a high level on these signals should result in the corresponding transistor in the PWM inverter being turned ON. The voltage level required at the PWM output pin to turn the transistor ON or OFF is a function of the logic between the pin and the transistor. Therefore, it is imperative that the user program
OCTRL[POLA] and OCTRL[POLB] before enabling the output pins. A fault condition can result in the PWM output being tristated, forced to a logic 1, or forced to a logic 0 depending on the values programmed into the OCTRL[PWMxFS] fields.

**Figure 55-25. Output Logic**

### 55.4.2.11 E-Capture

Commensurate with the idea of controlling both edges of an output signal, the Enhanced Capture (E-Capture) logic is designed to measure both edges of an input signal. As a result, when a submodule pin is configured for input capture, the CVALx registers associated with that pin are used to record the edge values.

The following figure is a block diagram of the E-Capture circuit. Upon entering the pin input, the signal is split into two paths. One goes straight to a mux input where software can select to pass the signal directly to the capture logic for processing. The other path connects the signal to an 8 bit counter which counts both the rising and falling edges of the signal. The output of this counter is compared to an 8 bit value that is specified by the user (EDGCMPx) and when the two values are equal, the comparator generates a pulse that resets the counter. This pulse is also supplied to the mux input where software can select it to be processed by the capture logic. This feature permits the E-Capture circuit to count up to 256 edge events before initiating a capture event. This feature is useful for
dividing down high frequency signals for capture processing so that capture interrupts
don't overwhelm the CPU. Also, this feature can be used to simply generate an interrupt
after "n" events have been counted.

This logic is repeated for PWM_A, PWM_B, and PWM_X inputs.

Based on the mode selection, the mux selects either the pin input or the compare output
from the count/compare circuit to be processed by the capture logic. The selected signal
is routed to two separate capture circuits which work in tandem to capture sequential
edges of the signal. The type of edge to be captured by each circuit is determined by
CAPTCTRLx[EDGx1] and CAPTCTRLx[EDGx0], whose functionality is listed in the
preceding figure. Also, controlling the operation of the capture circuits is the arming
logic which allows captures to be performed in a free running (continuous) or one shot
fashion. In free running mode, the capture sequences will be performed indefinitely. If
both capture circuits are enabled, they will work together in a ping-pong style where a
capture event from one circuit leads to the arming of the other and vice versa. In one shot
mode, only one capture sequence will be performed. If both capture circuits are enabled,
capture circuit 0 is first armed and when a capture event occurs, capture circuit 1 is
armed. Once the second capture occurs, further captures are disabled until another
capture sequence is initiated. Both capture circuits are also capable of generating an
interrupt to the CPU.

Figure 55-26. Enhanced Capture (E-Capture) Logic
55.4.2.12 Fault Protection

Fault protection can control any combination of PWM output pins. Faults are generated by a logic one on any of the FAULTx pins. This polarity can be changed via FCTRL[FLVL]. Each FAULTx pin can be mapped arbitrarily to any of the PWM outputs. When fault protection hardware disables PWM outputs, the PWM generator continues to run, only the output pins are forced to logic 0, logic 1, or tristated depending the values of OCTRL[PWMxFS].

The fault decoder disables PWM pins selected by the fault logic and the disable mapping (DISMAPn) registers. The following figure shows an example of the fault disable logic. Each bank of bits in DISMAPn control the mapping for a single PWM pin. See the following table.

The fault protection is enabled even when the PWM module is not enabled; therefore, a fault will be latched in and must be cleared in order to prevent an interrupt when the PWM is enabled.
Figure 55-27. Fault Decoder for PWM_A

55.4.2.12.1 Fault Pin Filter

Each fault pin has a programmable filter that can be bypassed. The sampling period of the filter can be adjusted with FFILT[FILT_PER]. The number of consecutive samples that must agree before an input transition is recognized can be adjusted using FFILT[FILT_CNT]. Setting FFILT[FILT_PER] to all 0 disables the input filter for a given FAULTx pin.

Upon detecting a logic 0 on the filtered FAULTx pin (or a logic 1 if FCTRL[FLVLx] is set), the corresponding FSTS[FFPINx] and fault flag, FSTS[FFLAGx], bits are set. FSTS[FFPINx] remains set as long as the filtered FAULTx pin is zero. Clear FSTS[FFLAGx] by writing a logic 1 to FSTS[FFLAGx].

If the FIEx, FAULTx pin interrupt enable bit is set, FSTS[FFLAGx] generates a CPU interrupt request. The interrupt request latch remains set until:

- Software clears FSTS[FFLAGx] by writing a logic one to the bit
- Software clears the FIEx bit by writing a logic zero to it
- A reset occurs

Even with the filter enabled, there is a combinational path from the FAULTx inputs to the PWM pins. This logic is also capable of holding a fault condition in the event of loss of clock to the PWM module.

55.4.2.12.2 Automatic Fault Clearing

Setting an automatic clearing mode bit, FCTRL[FAUTOx], configures faults from the FAULTx pin for automatic clearing.

When FCTRL[FAUTOx] is set, disabled PWM pins are enabled when the FAULTx pin returns to logic one and a new PWM full or half cycle begins. See the following figure. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle. Clearing FSTS[FFLAGx] does not affect disabled PWM pins when FCTRL[FAUTOx] is set.
55.4.2.12.3 Manual Fault Clearing

Clearing the automatic clearing mode bit, FCTRL[FAUTOx], configures faults from the FAULTx pin for manual clearing:

- If the fault safety mode bits, FCTRL[FSAFEx], are clear, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag
  - The pins are enabled when the next PWM full or half cycle begins regardless of the logic level detected by the filter at the FAULTx pin. See the first following figure. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.

- If the fault safety mode bits, FCTRL[FSAFEx], are set, then PWM pins disabled by the FAULTx pins are enabled when:
  - Software clears the corresponding FSTS[FFLAGx] flag
  - The filter detects a logic one on the FAULTx pin at the start of the next PWM full or half cycle boundary. See the second following figure. If FSTS[FFULLx] is set, then the disabled PWM pins are enabled at the start of a full cycle. If FSTS[FHALFx] is set, then the disabled PWM pins are enabled at the start of a half cycle.
Fault protection also applies during software output control when the SEL23 and SEL45 fields are set to select OUT23 and OUT45 bits or PWM_EXTA and PWM_EXTB. Fault clearing still occurs at half PWM cycle boundaries while the PWM generator is engaged, MCTRL[RUN] equals one. But the OUTx bits can control the PWM pins while the PWM generator is off, MCTRL[RUN] equals zero. Thus, fault clearing occurs at IPBus cycles while the PWM generator is off and at the start of PWM cycles when the generator is engaged.

55.4.2.12.4 Fault Testing

FTST[FTEST] is used to simulate a fault condition on each of the fault inputs within that fault channel.

55.4.3 PWM Generator Loading
55.4.3.1 Load Enable

MCTRL[LDOK] enables loading of the following PWM generator parameters:

- The prescaler divisor—from CTRL[PRSC]
- The PWM period and pulse width—from the INIT and VALx registers

MCTRL[LDOK] allows software to finish calculating all of these PWM parameters so they can be synchronously updated. The CTRL[PRSC], INIT, and VALx registers are loaded by software into a set of outer buffers. When MCTRL[LDOK] is set, these values are transferred to an inner set of registers at the beginning of the next PWM reload cycle to be used by the PWM generator. These values can be transferred to the inner set of registers immediately upon setting MCTRL[LDOK] if CTRL[LDMOD] is set. Set MCTRL[LDOK] by reading it when it is a logic zero and then writing a logic one to it. After loading, MCTRL[LDOK] is automatically cleared.

55.4.3.2 Load Frequency

CTRL[LDFQ] selects an integral loading frequency of one to 16 PWM reload opportunities. CTRL[LDFQ] takes effect at every PWM reload opportunity, regardless the state of MCTRL[LDOK]. CTRL[HALF] and CTRL[FULL] control reload timing. If CTRL[FULL] is set, a reload opportunity occurs at the end of every PWM cycle when the count equals VAL1. If CTRL[HALF] is set, a reload opportunity occurs at the half cycle when the count equals VAL0. If both CTRL[HALF] and CTRL[FULL] are set, a reload opportunity occurs twice per PWM cycle when the count equals VAL1 and when it equals VAL0.

![Figure 55-31. Full Cycle Reload Frequency Change](image)
55.4.3.3 Reload Flag

At every reload opportunity the PWM Reload Flag (STS[RF]) is set. Setting STS[RF] happens even if an actual reload is prevented by MCTRL[LDOK]. If the PWM reload interrupt enable bit, INTEN[RIE], is set, the STS[RF] flag generates CPU interrupt requests allowing software to calculate new PWM parameters in real time. When INTEN[RIE] is not set, reloads still occur at the selected reload rate without generating CPU interrupt requests.
55.4.3.4 Reload Errors

Whenever one of the VALx, FRACVALx, or CTRL[PRSC] registers is updated, the STS[RUF] flag is set to indicate that the data is not coherent. STS[RUF] will be cleared by a successful reload which consists of the reload signal while MCTRL[LDOK] is set. If STS[RUF] is set and MCTRL[LDOK] is clear when the reload signal occurs, a reload error has taken place and STS[REF] is set. If STS[RUF] is clear when a reload signal asserts, then the data is coherent and no error will be flagged.

55.4.3.5 Initialization

Initialize all registers and set MCTRL[LDOK] before setting MCTRL[RUN].

Note

Even if MCTRL[LDOK] is not set, setting MCTRL[RUN] also sets the STS[RF] flag. To prevent a CPU interrupt request, clear INTEN[RIE] before setting MCTRL[RUN].

The PWM generator uses the last values loaded if MCTRL[RUN] is cleared and then set while MCTRL[LDOK] equals zero.

When MCTRL[RUN] is cleared:

- The STS[RF] flag and pending CPU interrupt requests are not cleared
- All fault circuitry remains active
- Software/external output control remains active
- Deadtime insertion continues during software/external output control

55.5 Resets

All PWM registers are reset to their default values upon any system reset.

The reset forces all registers to their reset states and tri-states the PWM outputs.
## 55.6 Interrupts

Each of the submodules within the eFlexPWM module can generate an interrupt from several sources. The fault logic can also generate interrupts. The interrupt service routine (ISR) must check the related interrupt enables and interrupt flags to determine the actual cause of the interrupt.

55.7 DMA

Each submodule can request a DMA read access for its capture FIFOs and a DMA write request for its double buffered VALx registers.

### 55.8 PWM register descriptions

The address of a register is the sum of a base address and an address offset. The base address is defined at the core level, and the address offset is defined at the module level. The PWM module has a set of registers for each PWM submodule, for the configuration logic, and for each fault channel. While the registers are 16-bit wide, they can be accessed in pairs as 32-bit registers.

Submodule registers are repeated for each PWM submodule. To designate which submodule they are in, register names are prefixed with SM0, SM1, SM2, and SM3. The base address of submodule 0 is the same as the base address for the PWM module as a whole. The base address of submodule 1 is offset $60 from the base address for the PWM module as a whole. This $60 offset is based on the number of registers in a submodule. The base address of submodule 2 is equal to the base address of submodule 1 plus this same $60 offset. The pattern repeats for the base address of submodule 3.

The base address of the configuration registers is equal to the base address of the PWM module as a whole plus an offset of $180.

Fault channel registers are repeated for each fault channel. To designate which fault channel they are in, register names are prefixed with F0 and F1. The base address of fault channel 0 is equal to the base address of the PWM module as a whole plus an offset of $18C. The base address of fault channel 1 is the base address of fault channel 0 + $4. This $4 offset is based on the number of registers in a fault channel. Each of the four fields in the fault channel registers corresponds to fault inputs 3-0.
55.8.1 PWM Memory map

Base address: 403D_C000 for FlexPWM1; 403E_0000 for FlexPWM2; 403E_4000 for FlexPWM3; 403E_8000 for FlexPWM4.

NOTE

PWM_X only applicable to FlexPWM1, while FlexPWM2/3/4 do not have the PWMX outputs or inputs.

### 55.8.3 Initial Count Register (SM0INIT - SM3INIT)

#### 55.8.3.1 Offset

For a = 0 to 3:

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMaINIT</td>
<td>2h + (a × 60h)</td>
</tr>
</tbody>
</table>
55.8.3.2  Function

The 16-bit signed value in this buffered, read/write register defines the initial count value for the PWM in PWM clock periods. This is the value loaded into the submodule counter when local sync, master sync, or master reload is asserted (based on the value of CTRL2[INIT_SEL]) or when CTRL2[FORCE] is asserted and force init is enabled. For PWM operation, the buffered contents of this register are loaded into the counter at the start of every PWM cycle. This register is not byte accessible.

**NOTE**

The INIT register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. This register cannot be written when MCTRL[LDOK] is set. Reading INIT reads the value in a buffer and not necessarily the value the PWM generator is currently using.

Table continues on the next page...
### Field: Function

This bit determines if the PWM_A and PWM_B channels will be independent PWMs or a complementary PWM pair.

- 0b - PWM_A and PWM_B form a complementary PWM pair.
- 1b - PWM_A and PWM_B outputs are independent PWMs.

</tr>
</tbody>
</table>

#### PWMM23_INIT

This read/write bit determines the initial value for PWM23 and the value to which it is forced when FORCE_INIT is asserted.

#### PWMM45_INIT

This read/write bit determines the initial value for PWM45 and the value to which it is forced when FORCE_INIT is asserted.

#### PWMM_X_INIT

This read/write bit determines the initial value for PWM_X and the value to which it is forced when FORCE_INIT is asserted.

#### INIT_SEL

These read/write bits control the source of the INIT signal which goes to the counter.

- 00b - Local sync (PWM_X) causes initialization.
- 01b - Master reload from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0. The submodule counter will only reinitialize when a master reload occurs.
- 10b - Master sync from submodule 0 causes initialization. This setting should not be used in submodule 0 as it will force the INIT signal to logic 0.
- 11b - EXT_SYNC causes initialization.

#### FRCEN

This bit allows the CTRL2[FORCE] signal to initialize the counter without regard to the signal selected by CTRL2[INIT_SEL]. This is a software controlled initialization. A forced initialization will also assert the local reload if MCTRL[LDOK] is set.

- 0b - Initialization from a FORCE_OUT is disabled.
- 1b - Initialization from a FORCE_OUT is enabled.

#### FORCE

If CTRL2[FORCE_SEL] is set to 000, writing a 1 to this bit results in a FORCE_OUT event. This causes the following actions to be taken:

- The PWM_A and PWM_B output pins will assume values based on DTSRCSEL[SMxSEL23] and DTSRCSEL[SMxSEL45].
- If CTRL2[FRCEN] is set, the counter value will be initialized with the INIT register value.

#### FORCE_SEL

This read/write bit determines the source of the FORCE OUTPUT signal for this submodule.

- 000b - The local force signal, CTRL2[FORCE], from this submodule is used to force updates.
- 001b - The master force signal from submodule 0 is used to force updates. This setting should not be used in submodule 0 as it will hold the FORCE OUTPUT signal to logic 0.
- 010b - The local reload signal from this submodule is used to force updates without regard to the state of LDOK.
- 011b - The master reload signal from submodule0 is used to force updates if LDOK is set. This setting should not be used in submodule0 as it will hold the FORCE OUTPUT signal to logic 0.
- 100b - The local sync signal from this submodule is used to force updates.
- 101b - The master sync signal from submodule0 is used to force updates. This setting should not be used in submodule0 as it will hold the FORCE OUTPUT signal to logic 0.
- 110b - The external force signal, EXT_FORCE, from outside the PWM module causes updates.
- 111b - The external sync signal, EXT_SYNC, from outside the PWM module causes updates.

#### RELOAD_SEL

This read/write bit determines the source of the RELOAD signal for this submodule. When this bit is set, MCTRL[LDOK[0]] for submodule 0 should be used since the local MCTRL[LDOK] will be ignored.

#### 55.8.5.3 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-12</td>
<td>Load Frequency</td>
</tr>
<tr>
<td>LDFQ</td>
<td>These buffered read/write bits select the PWM load frequency. Reset clears LDFQ, selecting loading every PWM opportunity. A PWM opportunity is determined by HALF and FULL.</td>
</tr>
</tbody>
</table>

*Table continues on the next page...*
### PWM register descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NOTE:</strong></td>
<td>LDFQ takes effect when the current load cycle is complete, regardless of the state of MCTRL[LDOK]. Reading LDFQ reads the buffered values and not necessarily the values currently in effect.</td>
</tr>
</tbody>
</table>
| | 0000b - Every PWM opportunity  
 | 0001b - Every 2 PWM opportunities  
 | 0010b - Every 3 PWM opportunities  
 | 0011b - Every 4 PWM opportunities  
 | 0100b - Every 5 PWM opportunities  
 | 0101b - Every 6 PWM opportunities  
 | 0110b - Every 7 PWM opportunities  
 | 0111b - Every 8 PWM opportunities  
 | 1000b - Every 9 PWM opportunities  
 | 1001b - Every 10 PWM opportunities  
 | 1010b - Every 11 PWM opportunities  
 | 1011b - Every 12 PWM opportunities  
 | 1100b - Every 13 PWM opportunities  
 | 1101b - Every 14 PWM opportunities  
 | 1110b - Every 15 PWM opportunities  
 | 1111b - Every 16 PWM opportunities  |
| 11 | Half Cycle Reload  
 | This read/write bit enables half-cycle reloads. A half cycle is defined by when the submodule counter matches the VAL0 register and does not have to be half way through the PWM cycle.  
 | 0b - Half-cycle reloads disabled.  
 | 1b - Half-cycle reloads enabled.  |
| 10 | Full Cycle Reload  
 | This read/write bit enables full-cycle reloads. A full cycle is defined by when the submodule counter matches the VAL1 register. Either CTRL[HALF] or CTRL[FULL] must be set in order to move the buffered data into the registers used by the PWM generators or CTRL[LDMOD] must be set. If both CTRL[HALF] and CTRL[FULL] are set, then reloads can occur twice per cycle.  
 | 0b - Full-cycle reloads disabled.  
 | 1b - Full-cycle reloads enabled.  |
| 9-8 | Deadtime  
 | These read only bits reflect the sampled values of the PWM_X input at the end of each deadtime. Sampling occurs at the end of deadtime 0 for DT[0] and the end of deadtime 1 for DT[1]. Reset clears these bits.  |
| 7 | Compare Mode  
 | This bit controls how comparisons are made between the VAL* registers and the PWM submodule counter. This bit can only be written one time after which it requires a reset to release the bit for writing again.  
 | 0b - The VAL* registers and the PWM counter are compared using an "equal to" method. This means that PWM edges are only produced when the counter is equal to one of the VAL* register values. This implies that a PWMA output that is high at the end of a period will maintain this state until a match with VAL3 clears the output in the following period.  
 | 1b - The VAL* registers and the PWM counter are compared using an "equal to or greater than" method. This means that PWM edges are produced when the counter is equal to or greater than one of the VAL* register values. This implies that a PWMA output that is high at the end of a period could go low at the start of the next period if the starting counter value is greater than (but not necessarily equal to) the new VAL3 value.  |
| 6-4 | Prescaler  
 | These buffered read/write bits select the divide ratio of the PWM clock frequency selected by CTRL2[CLK_SEL].  |

*Table continues on the next page...*
### Field Function

**NOTE:** Reading CTRL[PRSC] reads the buffered values and not necessarily the values currently in effect. CTRL[PRSC] takes effect at the beginning of the next PWM cycle and only when the load okay bit, MCTRL[LDOK], is set or CTRL[LDMOD] is set. This field cannot be written when MCTRL[LDOK] is set.

<table>
<thead>
<tr>

<td>PWM clock frequency = $f_{clk}/4$</td>
</tr>
<tr>
<td>011b</td>
<td>PWM clock frequency = $f_{clk}/8$</td>
</tr>
<tr>
<td>100b</td>
<td>PWM clock frequency = $f_{clk}/16$</td>
</tr>
<tr>
<td>101b</td>
<td>PWM clock frequency = $f_{clk}/32$</td>
</tr>
<tr>
<td>110b</td>
<td>PWM clock frequency = $f_{clk}/64$</td>
</tr>
<tr>
<td>111b</td>
<td>PWM clock frequency = $f_{clk}/128$</td>
</tr>
</tbody>
</table>

#### 3 SPLIT
Split the DBLPWM signal to PWMA and PWMB

This read/write bit is only used when DBLEN is set. This bit allows the two PWM pulses generated by DBLEN to be split with one pulse on PWMA and one on PWMB. The two pulses within the same PWM period are created by an XOR function of the PWMA and PWMB sources. The splitting function causes PWMA to output the pulse that occurs when the PWMA source is 1 and the PWMB source is 0. The PWMB output occurs when the PWMB source is 1 and the PWMA source is 0. (See Double Switching PWMs.)

- 0b - DBLPWM is not split. PWMA and PWMB each have double pulses.
- 1b - DBLPWM is split to PWMA and PWMB.

#### 2 LDMOD
Load Mode Select

This read/write bit selects the timing of loading the buffered registers for this submodule.

- 0b - Buffered registers of this submodule are loaded and take effect at the next PWM reload if MCTRL[LDOK] is set.
- 1b - Buffered registers of this submodule are loaded and take effect immediately upon MCTRL[LDOK] being set. In this case it is not necessary to set CTRL[FULL] or CTRL[HALF].

#### 1 DBLX
PWMX Double Switching Enable

This read/write bit enables the double switching behavior on PWMX. When this bit is set, the PWMX output shall be the exclusive OR combination of PWMA and PWMB prior to polarity and masking considerations.

- 0b - PWMX double pulse disabled.
- 1b - PWMX double pulse enabled.

#### 0 DBLEN
Double Switching Enable

This read/write bit enables the double switching PWM behavior. (See Double Switching PWMs). Double switching is not compatible with fractional PWM clock generation. Make sure this bit is clear when setting FRCTRL[FRAC23_EN], FRCTRL[FRAC45_EN], or FRCTRL[FRAC1_EN].

- 0b - Double switching disabled.
- 1b - Double switching enabled.

### 55.8.6 Value Register 0 (SM0VAL0 - SM3VAL0)

#### 55.8.6.1 Offset

For $a = 0$ to $3$:

</tr>
</thead>
<tbody>
<tr>
<td>15-0</td>
<td>Value Register 1</td>
</tr>
</tbody>
</table>
| VAL1  | The 16-bit signed value written to this buffered, read/write register defines the modulo count value (maximum count) for the submodule counter. Upon reaching this count value, the counter reloads itself with the contents of the INIT register and asserts the local sync signal while resetting PWM_X. This register is not byte accessible.  

**NOTE:** The VAL1 register is buffered. The value written does not take effect until MCTRL[LDOK] is set and the next PWM load cycle begins or CTRL[LDMOD] is set. VAL1 cannot be written when MCTRL[LDOK] is set. Reading VAL1 reads the value in a buffer. It is not necessarily the value the PWM generator is currently using.  

**NOTE:** When using FRACVAL1, limit the maximum value of VAL1 to 0xFFFE for unsigned applications or to 0x7FFE for signed applications, to avoid counter rollovers caused by accumulating the fractional period defined by FRACVAL1.  

**NOTE:** If the VAL1 register defines the timer period (Local Sync is selected as the counter initialization signal), a 100% duty cycle cannot be achieved on the PWMX output. After the count reaches VAL1, the PWMX output is low for a minimum of one count every cycle. When the Master Sync signal (only originated by the Local Sync from sub-module 0) is used to control the timer period, the VAL1 register can be free for other functions such as PWM generation without the duty cycle limitation.

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 15 | PWMA_IN | PWM_A Input  
This read only bit shows the logic value currently being driven into the PWM_A input. The bit's reset state is undefined. |
| 14 | PWMB_IN | PWM_B Input  
This read only bit shows the logic value currently being driven into the PWM_B input. The bit's reset state is undefined. |
| 13 | PWMX_IN | PWM_X Input  
This read only bit shows the logic value currently being driven into the PWM_X input. The bit's reset state is undefined. |
| 12-11 | | RESERVED |
| 10 | POLA | PWM_A Output Polarity  
This bit inverts the PWM_A output polarity.  
0b - PWM_A output not inverted. A high level on the PWM_A pin represents the "on" or "active" state.  
1b - PWM_A output inverted. A low level on the PWM_A pin represents the "on" or "active" state. |
| 9 | POLB | PWM_B Output Polarity  
This bit inverts the PWM_B output polarity.  
0b - PWM_B output not inverted. A high level on the PWM_B pin represents the "on" or "active" state.  
1b - PWM_B output inverted. A low level on the PWM_B pin represents the "on" or "active" state. |
| 8 | POLX | PWM_X Output Polarity  
This bit inverts the PWM_X output polarity.  
0b - PWM_X output not inverted. A high level on the PWM_X pin represents the "on" or "active" state.  
1b - PWM_X output inverted. A low level on the PWM_X pin represents the "on" or "active" state. |
| 7-6 | | RESERVED |
| 5-4 | PWMAFS | PWM_A Fault State  
These bits determine the fault state for the PWM_A output during fault conditions and STOP mode. It may also define the output state during WAIT and DEBUG modes depending on the settings of CTRL2[WAITEN] and CTRL2[DBGEN].  
00b - Output is forced to logic 0 state prior to consideration of output polarity control.  
01b - Output is forced to logic 1 state prior to consideration of output polarity control.  
10b - Output is tristated.  
11b - Output is tristated. |
| 3-2 | PWMBFS | PWM_B Fault State  
These bits determine the fault state for the PWM_B output during fault conditions and STOP mode. It may also define the output state during WAIT and DEBUG modes depending on the settings of CTRL2[WAITEN] and CTRL2[DBGEN].  
00b - Output is forced to logic 0 state prior to consideration of output polarity control.  
01b - Output is forced to logic 1 state prior to consideration of output polarity control. |

## PWM register descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| RUF   | This read-only flag is set when one of the INIT, VALx, FRACVALx, or CTRL[PRSC] registers has been written, which indicates potentially non-coherent data in the set of double buffered registers. Clear this bit by a proper reload sequence consisting of a reload signal while MCTRL[LDOK] = 1. Reset clears this bit.  
  0b - No register update has occurred since last reload.  
  1b - At least one of the double buffered registers has been updated since the last reload. |
| 13    | Reload Error Flag  
  This read/write flag is set when a reload cycle occurs while MCTRL[LDOK] is 0 and the double buffered registers are in a non-coherent state (STS[RUF] = 1). Clear this bit by writing a logic one to this location. Reset clears this bit.  
  0b - No reload error occurred.  
  1b - Reload signal occurred with non-coherent data and MCTRL[LDOK] = 0. |
| 12    | Reload Flag  
  This read/write flag is set at the beginning of every reload cycle regardless of the state of MCTRL[LDOK]. Clear this bit by writing a logic one to this location when DMAEN[VALDE] is clear (non-DMA mode). This flag can also be cleared by the DMA done signal when DMAEN[VALDE] is set (DMA mode). Reset clears this bit.  
  0b - No new reload cycle since last STS[RF] clearing  
  1b - New reload cycle since last STS[RF] clearing |
| 11    | Capture Flag A1  
  This bit is set when a capture event occurs on the Capture A1 circuit. This bit is cleared by writing a one to this bit position if DMAEN[CA1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA1DE] is set (DMA mode). Reset clears this bit. |
| CFA1  |  
  10    | Capture Flag A0  
  This bit is set when a capture event occurs on the Capture A0 circuit. This bit is cleared by writing a one to this bit position if DMAEN[CA0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CA0DE] is set (DMA mode). Reset clears this bit. |
| CFA0  |  
  9     | Capture Flag B1  
  This bit is set when a capture event occurs on the Capture B1 circuit. This bit is cleared by writing a one to this bit position if DMAEN[CB1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB1DE] is set (DMA mode). Reset clears this bit. |
| CFB1  |  
  8     | Capture Flag B0  
  This bit is set when a capture event occurs on the Capture B0 circuit. This bit is cleared by writing a one to this bit position if DMAEN[CB0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CB0DE] is set (DMA mode). Reset clears this bit. |
| CFB0  |  
  7     | Capture Flag X1  
  This bit is set when a capture event occurs on the Capture X1 circuit. This bit is cleared by writing a one to this bit position if DMAEN[CX1DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX1DE] is set (DMA mode). Reset clears this bit. |
| CFX1  |  
  6     | Capture Flag X0  
  This bit is set when a capture event occurs on the Capture X0 circuit. This bit is cleared by writing a one to this bit position if DMAEN[CX0DE] is clear (non-DMA mode) or by the DMA done signal if DMAEN[CX0DE] is set (DMA mode). Reset clears this bit. |
| CFX0  |  
  5-0   | Compare Flags  
  These bits are set when the submodule counter value matches the value of one of the VALx registers. Clear these bits by writing a 1 to a bit position.  
  000000b - No compare event has occurred for a particular VALx value.  
  000001b - A compare event has occurred for a particular VALx value. |

<td>9</td>
<td><strong>VALDE</strong> Value Registers DMA Enable</td>
</tr>
</tbody>
</table>
|        | This read/write bit enables DMA write requests for the VALx and FRACVALx registers when STS[RF] is set. Reset clears this bit.  
|        | 0b - DMA write requests disabled              |
|        | 1b - DMA write requests for the VALx and FRACVALx registers enabled |
| 8      | **FAND** FIFO Watermark AND Control           |
|        | This read/write bit works in conjunction with the DMAEN[CAPTDE] field when it is set to watermark mode (DMAEN[CAPTDE] = 01). While DMAEN[CAxDE], DMAEN[CBxDE], and DMAEN[CXxDE] determine which FIFO watermarks the DMA read request is sensitive to, this bit determines if the selected watermarks are AND’ed together or OR’ed together in order to create the request.  
|        | 0b - Selected FIFO watermarks are OR’ed together.  
|        | 1b - Selected FIFO watermarks are AND’ed together. |
| 7-6    | **CAPTDE** Capture DMA Enable Source Select   |
|        | These read/write bits select the source of enabling the DMA read requests for the capture FIFOs. Reset clears these bits.  
|        | 00b - Read DMA requests disabled.              |
|        | 01b - Exceeding a FIFO watermark sets the DMA read request. This requires at least one of DMAEN[CA1DE], DMAEN[CA0DE], DMAEN[CB1DE], DMAEN[CB0DE], DMAEN[CX1DE], or DMAEN[CX0DE] to also be set in order to determine to which watermark(s) the DMA request is sensitive.  
|        | 10b - A local sync (VAL1 matches counter) sets the read DMA request.  
|        | 11b - A local reload (STS[RF] being set) sets the read DMA request. |
| 5      | **CA1DE** Capture A1 FIFO DMA Enable           |
|        | This read/write bit enables DMA read requests for the Capture A1 FIFO data when STS[CFA1] is set. Reset clears this bit. Do not set both this bit and INTEN[CA1IE]. |
| 4      | **CA0DE** Capture A0 FIFO DMA Enable           |
|        | This read/write bit enables DMA read requests for the Capture A0 FIFO data when STS[CFA0] is set. Reset clears this bit. Do not set both this bit and INTEN[CA0IE]. |
| 3      | **CB1DE** Capture B1 FIFO DMA Enable           |
|        | This read/write bit enables DMA read requests for the Capture B1 FIFO data when STS[CFB1] is set. Reset clears this bit. Do not set both this bit and INTEN[CB1IE]. |

</tbody>
</table>
55.8.25  Deadtime Count Register 0 (SM0DTCNT0 - SM3DTCNT0)

55.8.25.1  Offset

For a = 0 to 3:

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMaDTCNT0</td>
<td>30h + (a × 60h)</td>
</tr>
</tbody>
</table>

55.8.25.2  Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles. The DTCNTx registers are not byte accessible.

55.8.25.3  Diagram

```
Bits  | 15 | 14 | 13 | 12 | 11 | 10 | 9  | 8  | 7  | 6  | 5  | 4  | 3  | 2  | 1  | 0  |
R    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
W    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |    |
Reset| 0  | 0  | 0  | 0  | 0  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  | 1  |

DTCNT0
```

55.8.25.4  Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-0</td>
<td>DTCNT0</td>
</tr>
<tr>
<td>DTCNT0</td>
<td></td>
</tr>
</tbody>
</table>

The DTCNT0 field is interpreted differently depending on whether or not the fractional delays are being used (FRCNTRL[FRAC23_EN] is set). If the fractional delays are off, then the upper 5 bits of DTCNT0 are ignored and the remaining 11 bits are used to specify the number of cycles of deadtime. In this case the maximum value is 0x07FF which indicates 2047 cycles of deadtime. If the fractional delays are being used, then the upper 11 bits of DTCNT0 represent the number of whole cycles of deadtime and the lower 5 bits of each register represent the fractional cycle added to the whole number. In this case the maximum value is 0xFFFF which represents 2047 31/32 cycles of deadtime.
55.8.26 Deadtime Count Register 1 (SM0DTCNT1 - SM3DTCNT1)

55.8.26.1 Offset

For $a = 0$ to $3$:

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>SMaDTCNT1</td>
<td>$32h + (a \times 60h)$</td>
</tr>
</tbody>
</table>

55.8.26.2 Function

Deadtime operation applies only to complementary channel operation. The values written to the DTCNTx registers are in terms of IPBus clock cycles regardless of the setting of CTRL[PRSC] and/or CTRL2[CLK_SEL]. Reset sets the deadtime count registers to a default value of 0x07FF, selecting a deadtime of 2047 IPBus clock cycles. The DTCNTx registers are not byte accessible.

55.8.26.3 Diagram

![Diagram](image)

55.8.26.4 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-0</td>
<td>DTCNT1</td>
</tr>
<tr>
<td>DTCNT1</td>
<td></td>
</tr>
</tbody>
</table>
The DTCNT1 field is interpreted differently depending on whether or not the fractional delays are being used (FRCNTRL[FRAC45_EN] is set). If the fractional delays are off, then the upper 5 bits of DTCNT1 are ignored and the remaining 11 bits are used to specify the number of cycles of deadtime. In this case the maximum value is 0x07FF which indicates 2047 cycles of deadtime. If the fractional delays are being used, then the upper 11 bits of DTCNT1 represent the number of whole cycles of deadtime and the lower 5 bits of each register represent the fractional cycle added to the whole number. In this case the maximum value is 0xFFFF which represents 2047 31/32 cycles of deadtime.

The DTCNT1 field is used to control the deadtime during 0 to 1 transitions of the PWM_B output (assuming normal polarity).

### 55.8.29.3 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 15-13 CB1CNT | Capture B1 FIFO Word Count  
This field reflects the number of words in the Capture B1 FIFO.                               |
| 12-10 CB0CNT | Capture B0 FIFO Word Count  
This field reflects the number of words in the Capture B0 FIFO.                               |
| 9-8 CFBWM | Capture B FIFOs Water Mark  
This field represents the water mark level for capture B FIFOs. The capture flags, STS[CFB1] and STS[CFB0], won’t be set until the word count of the corresponding FIFO is greater than this water mark level. |
| 7 EDGCNTB_EN | Edge Counter B Enable  
This bit enables the edge counter which counts rising and falling edges on the PWM_B input signal.  
0b - Edge counter disabled and held in reset  
1b - Edge counter enabled |
| 6 INP_SEL B | Input Select B  
This bit selects between the raw PWM_B input signal and the output of the edge counter/compare  
circuitry as the source for the input capture circuit.                                           |

## PWM register descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>0b - Raw PWM_B input signal selected as source. 1b - Output of edge counter/compare selected as source. Note that when this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLB[EDGB0] and CAPTCTRLB[EDGB1] fields are ignored. The software must still place a value other than 00 in either or both of the CAPTCTRLB[EDGB0] and/or CAPTCTRLB[EDGB1] fields in order to enable one or both of the capture registers.</td>
<td></td>
</tr>
<tr>
<td>5-4</td>
<td>Edge B 1</td>
</tr>
<tr>
<td>3-2</td>
<td>Edge B 0</td>
</tr>
<tr>
<td>1</td>
<td>One Shot Mode B</td>
</tr>
<tr>
<td>0</td>
<td>Arm B</td>
</tr>
</tbody>
</table>

### Edge B 1
These bits control the input capture 1 circuitry by determining which input edges cause a capture event.
- 00b - Disabled
- 01b - Capture falling edges
- 10b - Capture rising edges
- 11b - Capture any edge

### Edge B 0
These bits control the input capture 0 circuitry by determining which input edges cause a capture event.
- 00b - Disabled
- 01b - Capture falling edges
- 10b - Capture rising edges
- 11b - Capture any edge

### One Shot Mode B
This bit selects between free running and one shot mode for the input capture circuitry.
- 0b - Free running mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit.
- 1b - One shot mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after CAPTCTRLB[ARMB] is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and CAPTCTRLB[ARMB] is cleared. No further captures will be performed until CAPTCTRLB[ARMB] is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and CAPTCTRLB[ARMB] is then cleared.

### Arm B
Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event.
- 0b - Input capture operation is disabled.
- 1b - Input capture operation as specified by CAPTCTRLB[EDGBx] is enabled.

## 55.8.31.3 Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| 15-13 CX1CNT | Capture X1 FIFO Word Count  
This field reflects the number of words in the Capture X1 FIFO. |
| 12-10 CX0CNT | Capture X0 FIFO Word Count  
This field reflects the number of words in the Capture X0 FIFO. |
| 9-8 CFXWM | Capture X FIFOs Water Mark  
This field represents the water mark level for capture X FIFOs. The capture flags, STS[CFX1] and STS[CFX0], won't be set until the word count of the corresponding FIFO is greater than this water mark level. |
| 7 EDGNTX_EN | Edge Counter X Enable  
This bit enables the edge counter which counts rising and falling edges on the PWM_X input signal.  
0b - Edge counter disabled and held in reset  
1b - Edge counter enabled |
| 6 INP_SELX | Input Select X  
This bit selects between the raw PWM_X input signal and the output of the edge counter/compare circuitry as the source for the input capture circuit.  
0b - Raw PWM_X input signal selected as source.  
1b - Output of edge counter/compare selected as source. Note that when this bitfield is set to 1, the internal edge counter is enabled and the rising and/or falling edges specified by the CAPTCTRLX[EDGX0] and CAPTCTRLX[EDGX1] fields are ignored. The software must still place a value other than 00 in either or both of the CAPTCTRLX[EDGX0] and/or CAPTCTRLX[EDGX1] fields in order to enable one or both of the capture registers. |
| 5-4 EDGX1 | Edge X 1  
These bits control the input capture 1 circuitry by determining which input edges cause a capture event.  
00b - Disabled  
01b - Capture falling edges  
10b - Capture rising edges  
11b - Capture any edge |
| 3-2 EDGX0 | Edge X 0  
These bits control the input capture 0 circuitry by determining which input edges cause a capture event.  
00b - Disabled |
### Field and Function

<table>

</tbody>
</table>

#### One Shot Mode Aux

This bit selects between free running and one shot mode for the input capture circuitry.

- 0b - Free running mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and capture circuit 0 is re-armed. The process continues indefinitely. If only one of the capture circuits is enabled, then captures continue indefinitely on the enabled capture circuit.

- 1b - One shot mode is selected. If both capture circuits are enabled, then capture circuit 0 is armed first after the ARMX bit is set. Once a capture occurs, capture circuit 0 is disarmed and capture circuit 1 is armed. After capture circuit 1 performs a capture, it is disarmed and the ARMX bit is cleared. No further captures will be performed until the ARMX bit is set again. If only one of the capture circuits is enabled, then a single capture will occur on the enabled capture circuit and the ARMX bit is then cleared.

#### Arm X

Setting this bit high starts the input capture process. This bit can be cleared at any time to disable input capture operation. This bit is self-cleared when in one shot mode and one or more of the enabled capture circuits has had a capture event.

- 0b - Input capture operation is disabled.
- 1b - Input capture operation as specified by CAPTCTRLX[EDGXx] is enabled.

## 55.8.46 Mask Register (MASK)
55.8.46.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>MASK</td>
<td>182h</td>
</tr>
</tbody>
</table>

55.8.46.2 Function

MASK is double buffered and does not take effect until a FORCE_OUT event occurs within the appropriate submodule. Reading MASK reads the buffered values and not necessarily the values currently in effect. This double buffering can be overridden by setting the UPDATE_MASK bits.

55.8.46.3 Diagram

55.8.49.4  Fields

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>15-12</td>
<td>Current Polarity</td>
</tr>
<tr>
<td>IPOL</td>
<td>The four buffered read/write bits of this field correspond to submodules 3-0, respectively. Each bit selects between PWM23 and PWM45 as the source for the generation of the complementary PWM pair output for the corresponding submodule. MCTRL[IPOL] is ignored in independent mode. MCTRL[IPOL] does not take effect until a FORCE_OUT event takes place in the appropriate submodule. Reading MCTRL[IPOL] reads the buffered value and not necessarily the value currently in effect. 0000b - PWM23 is used to generate complementary PWM pair in the corresponding submodule. 0001b - PWM45 is used to generate complementary PWM pair in the corresponding submodule.</td>
</tr>
<tr>
<td>11-8</td>
<td>Run</td>
</tr>
<tr>
<td>RUN</td>
<td>The four read/write bits of this field enable the clocks to the PWM generator of submodules 3-0, respectively. The corresponding MCTRL[RUN] bit must be set for each submodule that is using its input capture functions or is using the local reload as its reload source. When this bit equals zero, the submodule counter is reset. A reset clears this field.</td>
</tr>
</tbody>
</table>

Table continues on the next page...
Field | Function
---|---
0000b | PWM generator is disabled in the corresponding submodule.
0001b | PWM generator is enabled in the corresponding submodule.
7-4 CLDOK | Clear Load Okay
The 4 bits of CLDOK field correspond to submodules 3-0, respectively. Each write-only bit is used to clear the corresponding bit of MCTRL[LDOK]. Write a 1 to CLDOK to clear the corresponding MCTRL[LDOK] bit. If a reload occurs within a submodule with the corresponding MCTRL[LDOK] bit set at the same time that MCTRL[CLDOK] is written, then the reload in that submodule will not be performed and MCTRL[LDOK] will be cleared. CLDOK bit is self-clearing and always reads as a 0.
3-0 LDOK | Load Okay
The 4 bits of LDOK field correspond to submodules 3-0, respectively. Each read/set bit loads CTRL[PRSC] and the INIT, FRACVALx, and VALx registers of the corresponding submodule into a set of buffers. The buffered prescaler divisor, submodule counter modulus value, and PWM pulse width take effect at the next PWM reload if CTRL[LDMOD] is clear or immediately if CTRL[LDMOD] is set. Set the corresponding MCTRL[LDOK] bit by reading it when it is logic zero and then writing a logic one to it. The VALx, FRACVALx,INIT, and CTRL[PRSC] registers of the corresponding submodule cannot be written while the the corresponding MCTRL[LDOK] bit is set.

In Master Reload Mode (CTRL2[RELOAD_SEL]=1), it is only necessary to set the LDOK bit corresponding to submodule0; however, it is recommended to also set the LDOK bit of the slave submodules, to prevent unwanted writes to the registers in the slave submodules.

The MCTRL[LDOK] bit is automatically cleared after the new values are loaded, or it can be manually cleared before a reload by writing a logic 1 to the appropriate MCTRL[CLDOK] bit. LDOK bits cannot be written with a zero. MCTRL[LDOK] can be set in DMA mode when the DMA indicates that it has completed the update of all CTRL[PRSC], INIT,FRACVALx, and VALx registers in the corresponding submodule. Reset clears LDOK field.

- 0000b - Do not load new values.
- 0001b - Load prescaler, modulus, and PWM values of the corresponding submodule.

<td>Monitor PLL State</td>
</tr>
</tbody>
</table>

These bits are used to control disabling of the fractional delay block when the chip PLL is unlocked and/or missing its input reference. The fractional delay block requires a continuous 200 MHz clock from the PLL. If this clock turns off when the fractional delay block is being used, then the output of the fractional delay block can be stuck high or low even if the PLL restarts. When this control bit is set, PLL problems cause the fractional delay block to be disabled until the PLL returns to a locked state. Once the PLL is receiving a proper reference and is locked, the fractional delay block requires a 25 µs startup time just as if the FRCTRL[FRAC*_EN] bits had been turned off and turned on again.

If PLL monitoring is disabled, then software should manually clear and then set the FRCTRL[FRAC*_EN] bits when the PLL loses its reference or loses lock. This will cause the fractional delay block to be disabled and restarted.

If the fractional delay block is not being used, then the value of these bits do not matter.

- 00b - Not locked. Do not monitor PLL operation. Resetting of the fractional delay block in case of PLL losing lock will be controlled by software.
- 01b - Not locked. Monitor PLL operation to automatically disable the fractional delay block when the PLL encounters problems.
- 10b - Locked. Do not monitor PLL operation. Resetting of the fractional delay block in case of PLL losing lock will be controlled by software. These bits are write protected until the next reset.
- 11b - Locked. Monitor PLL operation to automatically disable the fractional delay block when the PLL encounters problems. These bits are write protected until the next reset.

### 55.8.51 Fault Control Register (FCTRL0)

#### 55.8.51.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>

<tr>
<td>7-4</td>
<td>Fault Safety Mode</td>
</tr>
<tr>
<td>FSAFE</td>
<td>These read/write bits select the safety mode during manual fault clearing. A reset clears this field.</td>
</tr>
<tr>
<td></td>
<td>FSTS[FFPINx] may indicate a fault condition still exists even though the actual fault signal at the FAULTx pin is clear due to the fault filter latency.</td>
</tr>
<tr>
<td></td>
<td>0000b - Normal mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear at the start of a half cycle or full cycle depending on the state of FSTS[FFULL] without regard to the state of FSTS[FFPINx]. The PWM outputs disabled by this fault input will not be re-enabled until the actual FAULTx input signal de-asserts since the fault input will combinationally disable the PWM outputs (as programmed in DISMAPn).</td>
</tr>
<tr>
<td></td>
<td>0001b - Safe mode. PWM outputs disabled by this fault are not enabled until FSTS[FFLAGx] is clear and FSTS[FFPINx] is clear at the start of a half cycle or full cycle depending on the state of FSTS[FFULL].</td>
</tr>
<tr>
<td>3-0</td>
<td>Fault Interrupt Enables</td>
</tr>
</tbody>
</table>
This read/write field enables CPU interrupt requests generated by the FAULTx pins. A reset clears this field.

NOTE: The fault protection circuit is independent of the FIE bit and is always active. If a fault is detected, the PWM outputs are disabled according to the disable mapping register.

- 0000b - FAULTx CPU interrupt requests disabled.
- 0001b - FAULTx CPU interrupt requests enabled.

#### 55.8.53.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>FFILT0</td>
<td>190h</td>
</tr>
</tbody>
</table>

#### 55.8.53.2 Function

The settings in this register are shared among each of the fault input filters within the fault channel.

Input filter considerations include:

- The FILT_PER value should be set such that the sampling period is larger than the period of the expected noise. This way a noise spike will only corrupt one sample. The FILT_CNT value should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the FILT_CNT+3 power.

- The values of FILT_PER and FILT_CNT must also be traded off against the desire for minimal latency in recognizing input transitions. Turning on the input filter (setting FILT_PER to a non-zero value) introduces a latency of (FILT_CNT+4) x FILT_PER x IPBus clock period). Note that even when the filter is enabled, there is a
combinational path to disable the PWM outputs. This is to ensure rapid response to fault conditions and also to ensure fault response if the PWM module loses its clock. The latency induced by the filter will be seen in the time to set FSTS[FFLAG] and FSTS[FFPIN].

<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
<tbody>
<tr>
<td>15 GSTR</td>
<td>Fault Glitch Stretch Enable</td>
</tr>
<tr>
<td>10-8 FILT_CNT</td>
<td>Fault Filter Count</td>
</tr>
<tr>
<td>7-0 FILT_PER</td>
<td>Fault Filter Period</td>
</tr>
</tbody>
</table>

- **GSTR**: Fault Glitch Stretch Enable
  - This bit is used to enable the fault glitch stretching logic. This logic ensures that narrow fault glitches are stretched to be at least 2 IPBus clock cycles wide. In some cases a narrow fault input can cause problems due to the short PWM output shutdown/re-activation time. The stretching logic ensures that a glitch on the fault input, when the fault filter is disabled, will be registered in the fault flags.
  - 0b - Fault input glitch stretching is disabled.
  - 1b - Input fault signals will be stretched to at least 2 IPBus clock cycles.

- **FILT_CNT**: Fault Filter Count
  - These bits represent the number of consecutive samples that must agree prior to the input filter accepting an input transition. The number of samples is the decimal value of this field plus three: the bitfield value of 0-7 represents 3-10 samples, respectively. The value of FILT_CNT affects the input latency.

- **FILT_PER**: Fault Filter Period
  - This 8-bit field applies universally to all fault inputs.
  - These bits represent the sampling period (in IPBus clock cycles) of the fault pin input filter. Each input is sampled multiple times at the rate specified by this field. If FILT_PER is 0x00 (default), then the input filter is bypassed. The value of FILT_PER affects the input latency.

**NOTE:** When changing values for FILT_PER from one non-zero value to another non-zero value, first write a value of zero to clear the filter.

No Combinational Path From Fault Input To PWM Output

This read/write field is used to control the combinational path from the fault inputs to the PWM outputs. When these bits are low (default), the corresponding fault inputs have a combinational path to the PWM outputs that are sensitive to these fault inputs (as defined by DISMAP0 and DISMAP1). This combinational path is a safety feature that ensures the output is disabled even if the SOC has a failure of its clocking system. The combinational path also means that a pulse on the fault input can cause a brief disable of the PWM output even if the fault pulse is not wide enough to get through the input filter and be latched in the fault logic. Setting these bits removes the combinational path and uses the filtered and latched fault signals as the fault source to disable the PWM outputs. This eliminates fault glitches from creating PWM output glitches but also increases the latency to respond to a real fault.

- 0000b - There is a combinational link from the fault inputs to the PWM outputs. The fault inputs are combined with the filtered and latched fault signals to disable the PWM outputs.
- 0001b - The direct combinational path from the fault inputs to the PWM outputs is disabled and the filtered and latched fault signals are used to disable the PWM outputs.

56.2 Introduction

The enhanced quadrature encoder/decoder module interfaces to position/speed sensors that are used in industrial motor control applications. Using 5 input signals (PHASEA, PHASEB, INDEX, TRIGGER, and HOME) from those position/speed sensors, the quadrature decoder module decodes shaft position, revolution count, and speed.

56.2.1 Features

- Includes logic to decode quadrature signals
- Inputs can be connected to a general purpose timer to make low speed velocity measurements
- Configurable digital filter for inputs
- Quadrature decoder filter can be bypassed
- 32-bit position counter capable of modulo counting
- Position counter can be initialized by software or external events
- 16-bit position difference register
- Compare function can indicate when shaft has reached a defined position
- A watchdog timer can detect a non-rotating shaft condition
- Preloadable 16-bit revolution counter
- Maximum count frequency equals the peripheral clock rate

### 56.2.2 System Block Diagram

The next figure shows the block diagram of the quadrature decoder module integrated into an SoC.

![System Block Diagram](image)

**Figure 56-1. System Block Diagram**

### 56.2.3 Decoder Block Diagram
56.2.3.1 Glitch Filter

Because the quadrature decoder logic must sense signal transitions, the signal inputs are first run through a glitch filter. This glitch filter has a digital delay line, which samples multiple time points on the signal and verifies a stable new signal state, before outputting this new signal state to the internal quadrature decoder logic. To adapt to a variety of signal bandwidths, the sample rate of this delay line is programmable.

56.2.3.2 Edge Detect State Machine

The edge detect state machine looks for changes in the 4 possible states of the filtered PHASEA and PHASEB inputs, which are used to calculate the direction of motion. This information is formatted as Count_Up and Count_Down signals. These signals are routed into up to 3 up/down counters:

- Position counter
- Revolution counter
- Position difference counter
56.2.3.3 Position Counter

The 32-bit position counter calculates up or down on every count pulse, generated by the difference of PHASEA and PHASEB. The position counter acts as an integration_info, whose count value is proportional to position. The direction of the count is determined by the Count_Up and Count_Down signals. Position counters may be initialized to a predetermined value by one of 3 different methods:

- Software-triggered event
- INDEX signal transition
- HOME signal transition

The INDEX and HOME signals can be programmed to interrupt the processor. Whenever the position counters (UPOS or LPOS) are read, a snapshot of the

- position counter
- position difference counter
- revolution counter

are each placed into their respective hold registers.

56.2.3.4 Position Difference Counter

The 16-bit position difference counter contains the position difference value occurring between each read of the position register. The position register counts up or down on every count pulse. The position difference counter acts as a differentiator, whose count value is proportional to the change in position since the last time the position counter was read.

When the position register, the position difference counter, or the revolution counter is read, the position difference of the counter's contents is copied into the position difference hold register (POSDH) and the position difference counter is cleared.

56.2.3.5 Position Difference Counter Hold

The Position Difference Counter Hold register stores a copy of the position difference counter at the time that the position register was read. When the position register is read, the position difference of the counter's contents is copied into the position difference hold register (POSDH), and the position difference counter is cleared.
56.2.3.6 Revolution Counter

The 16-bit up/down revolution counter is intended to count or integrate revolutions by counting index pulses. The direction of the count is determined by the Count_Up and Count_Down signals, determined by the Phase A and B inputs. A different count direction on the rising and falling edges of the index pulse indicates that the quadrature encoder changed direction on the index pulse.

56.2.3.7 Watchdog Timer

The watchdog timer ensures that the algorithm is indicating motion in the shaft; 2 successive counts indicate proper operation and will reset the timer.
- The timeout value is programmable.
- When a timeout occurs, an interrupt to the processor can be generated.

56.2.3.8 Pulse Accumulator Functionality

The logic can be programmed to integrate only selected transitions of the PHASEA signal. In this way, the position counter can be used as a pulse accumulator.
- The count direction is up.
- The pulse accumulator can also optionally be initialized by the INDEX input.

56.3 Signal Descriptions

Four external signals are multiplexed to the four pins (PHASEA, PHASEB, INDEX, HOME) of a quad timer module. Two internal signals (TRIGGER, POSMATCH) can be connected to other SoC resources.

### Table 56-2. Signals (continued)

<table>
<thead>
<tr>
<th>Signal</th>
<th>Description</th>
</tr>
</thead>
</table>
| **PHASEB** | Phase B Input | The PHASEB input can be connected to the other phase from a two-phase shaft quadrature encoder output.  
- The PHASEB input can be an input capture channel for one of the timer modules (in the SoC), which can be connected to using a crossbar switch.  
  Direction for two-phase shaft quadrature encoder output:  
- PHASEB is the trailing phase for a shaft rotating in the positive direction.  
- PHASEB is the leading phase for a shaft rotating in the negative direction. |
| **INDEX** | Index Input | • Normally connected to the index pulse output of a quadrature encoder, the INDEX pulse can optionally reset the position counter and the pulse accumulator of the quadrature decoder module. The INDEX pulse also causes a change of state on the revolution counter. The direction of this state change (increment or decrement) is calculated from the PHASEA and PHASEB inputs.  
- The INDEX input can be an input capture channel for one of the timer modules (in the SoC), which can be connected to using a crossbar switch. |
| **HOME** | Home Switch Input | The HOME input can be used by the quadrature decoder and the timer module.  
- The HOME input can be used to trigger the initialization of the position counters (UPOS and LPOS). Often the HOME signal is connected to a sensor on the motor or machine, sending notification that it has reached a defined home position.  
- The HOME signal can be connected to the timer module (in the SoC) using a crossbar switch. |
| **TRIGGER** | Trigger Input | The TRIGGER input can be used  
- to clear the position counters (UPOS and LPOS)  
- to take a snapshot of the POS, REV, and POSD registers  
- to indicate an elapsed time period, by connecting the TRIGGER input signal to a periodic pulse generator or timer |
| **POSMATCH** | Position Match Output | • To record the time at which the position of the shaft matches a user-defined compare value (COMP), the POSMATCH output can be used to trigger a timer channel.  
- Alternatively, to record the time at which the position information was read, (when the position counters (UPOS and LPOS), revolution counter (REV), or position difference counter (POSD) registers are read) the POSMATCH output can be used to trigger a timer channel. |

### 56.4 Functional Description

The next timing diagram shows the basic operation of a quadrature incremental position quadrature decoder.
56.4.1 Positive versus Negative Direction

A typical quadrature encoder has 3 outputs: PHASEA signal, PHASEB signal, INDEX pulse (not shown).

- If PHASEA leads PHASEB, then motion is in the positive direction.
- If PHASEA trails PHASEB, then motion is in the negative direction.

Transitions on these phases can be integrated to yield position or differentiated to yield velocity. The quadrature decoder is designed to perform these functions in hardware.

56.4.2 Prescaler for Slow or Fast Speed Measurement

- For applications with a fast moving shaft encoder, the speed can be computed by calculating the change in the position counter per unit time, or by reading the position difference counter register (POSD) and calculating speed.
- For applications with slow motor speeds and low line count quadrature encoders, the timer module enables high resolution velocity measurements by measuring the time period between quadrature phases.
  - The timer module uses a 16-bit free running counter operated from a prescaled version of the IPBus clock.
  - The prescaler divides the IPBus clock by values ranging from 1 to 128. A 60 MHz IPBus clock frequency would yield a resolution of from 17 ns to 2.1 μs and a maximum count period of from 1.09 ms to 140 ms. For example, with a 1000-tooth decoder, speeds could be calculated down to 0.11 rpm using a prescaler.
### 56.4.3 Holding Registers and Initializing Registers

Hold registers are associated with 3 types of counters:

- Position
- Position difference
- Revolution

When any of the counter registers is read, the contents of each counter register is written to the corresponding hold register. Taking a snapshot of the counters' values provides a consistent view of a system's position and the velocity to be attained. To capture a time stamp of when these registers are read, use the POSMATCH output with a timer channel.

The position counter is 32 bits wide. To ensure that the position counter can be reliably initialized with two 16-bit accesses, two registers (an upper and a lower initialization register) are provided. The upper initialization register (UINIT) and lower initialization register (LINIT) should be loaded with the desired value. Next, the position counter can be loaded by writing 1 to the Software-Triggered Initialization of Position Counters UPOS and LPOS bit (CTRL[SWIP]). Alternatively, either the INDEX-Triggered Initialization of Position Counters UPOS and LPOS bit (CTRL[XIP]) or the Enable HOME to Initialize Position Counters UPOS and LPOS bit (CTRL[HIP]) can enable the position counter to be initialized in response to a HOME or INDEX signal transition.

### 56.5 Resets

There are no special requirements. This module is reset by any system reset.

### 56.6 Clocks

The IPBus clock is the only clock required by this module in normal operation.

### 56.7 Interrupts

The following table lists the module interrupts.

<table>

56.8 ENC register descriptions

The address of a register is the sum of a base address and an address offset.
- Base address is defined at the MCU level
- Address offset is defined at the module level

For the base address, see the specific chip documentation. All memory locations base and offsets are given in hex.

56.8.1 ENC Memory map

ENCₙ base address: 403C_8000h + (n-1)×4000h, where n is from 1 to 4.

### 56.8.3 Input Filter Register (FILT)

#### 56.8.3.1 Offset

<table>
<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>FILT</td>
<td>2h</td>
</tr>
</tbody>
</table>

NXP Semiconductors
56.8.3.2 Function

The Input Filter Register sets the values of the input filter sample period (FILT_PER) and the input filter sample count (FILT_CNT).

- The Input Filter Sample Period (FILT_PER) should be set so that the sampling period is larger than the period of the expected noise. Doing this means that a noise spike will only corrupt one sample.
- The Input Filter Sample Count (FILT_CNT) should be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of FILT_CNT + 3.

The values of the Input Filter Sample Period (FILT_PER) and the Input Filter Sample Count (FILT_CNT) must also be traded off against the desire for minimal latency in recognizing valid input transitions. Turning on the input filter (setting the Input Filter Sample Period (FILT_PER) to a non-zero value) introduces a latency of \(((\text{FILT_CNT} + 3) \times \text{FILT_PER} + 2)\) IPBus clock periods.

The filter latency can be measured:

- Drive the quadrature decoder inputs (PHASEA, PHASEB, INDEX, HOME)
- Monitor the filtered output in the Input Monitor Register (IMR)
- Determine how many IPBus clock cycles that it takes before the output shows up, by using the following equations, where \(f\) is FILT_PER and \(s\) is FILT_CNT.
  - \(\text{DELAY} \text{ (IPBus clock cycles)} = f \times (s+3) + 1\) (to read the filtered output)
  - \(\text{DELAY} \text{ (IPBus clock cycles)} = f \times (s+3) + 2\) (to monitor the output in the IMR)

One more additional IPBus clock cycle is needed to read the filtered output, and 2 more IPBus clock cycles are needed to monitor the filtered output in the IMR. The sample rate is set when it reaches the number \(f\). The following examples use the preceding equations:

- Example: when \(f = 0\), the filter is bypassed: \(\text{DELAY} = 1\) or 2 clock cycles.
- Example: when \(f = 5\) and \(s = 2\): \(\text{DELAY} = 5 \times (2+3) + (1 \text{ or } 2) = 26\) or 27 clock cycles.

56.8.5.2 Function

The Position Difference Counter Register contains the position change in value occurring between each read of the Position Register. The value of the Position Difference Counter Register can be used to calculate velocity.

- The 16-bit Position Difference Counter computes up or down on every count pulse.
- This Position Difference Counter acts as a differentiator, whose count value is proportional to the change in position since the last time that the Position Counter was read.
- When the Position Registers (UPOS or LPOS), the Position Difference Counter (POSD), or the Revolution Counter (REV) is read, the Position Difference Counter's contents are copied into the Position Difference Hold Register (POSDH) and the Position Difference Counter is cleared.

56.8.15.2 Function
The Input Monitor Register contains the values of the raw and filtered PHASEA, PHASEB, INDEX, and HOME input signals. The reset value depends on the values of the raw and filtered values of PHASEA, PHASEB, INDEX, and HOME input signals:
- If these input pins are connected to a pull-up, then bits 0–7 of the IMR are all ones.
- If these input pins are connected to a pull-down device, then bits 0–7 of the Input Monitor Register (IMR) are all zeros.

56.8.16.2 Function
The Test Register controls and sets the frequency of a quadrature signal generator; it provides a quadrature test signal to the inputs of the quadrature decoder module.

- The TEST_COUNT value is counted down to zero when the test module is enabled (TEN = 1) and the count is enabled (TCE = 1).
- Each count value of one represents a single quadrature cycle interpreted as a count of one by the position counter (UPOS and LPOS) if it is enabled (TEN = 1, TCE = 1).
- Repeated writing of new values to TEST_COUNT can cause an extra phase transition and therefore an extra count by the Position Counter.
- The period field determines the length (in IPBus clock cycles) of each quadrature cycle phase.

The Test Register is a factory test feature; however, it can also be useful in customer software development and testing.

</tr>
</thead>
</table>
| OUTCTL | Output Control controls the pulsing of the POSMATCH output signal. This can control when a timer channel captures a timestamp.  
- 0b - POSMATCH pulses when a match occurs between the position counters (POS) and the compare value (COMP)  
- 1b - POSMATCH pulses when the UPOS, LPOS, REV, or POSD registers are read |
| REVMOD | Revolution Counter Modulus Enable selects how the revolution counter (REV) is incremented/decremented. By default, the revolution counter is controlled based on the count direction and the INDEX pulse. As an option, the revolution counter can be controlled using the roll-over/under detection during modulo counting.  
- 0b - Use INDEX pulse to increment/decrement revolution counter (REV)  
- 1b - Use modulus counting roll-over/under to increment/decrement revolution counter (REV) |
| ROIRQ | Roll-over Interrupt Request bit is set (=1) when the position counter (POS) rolls over from the MOD value to the INIT value, or from 0xFFFF_FFFF to 0x0000_0000.  
- Roll-over Interrupt Request will remain set until cleared by software  
- Write a one to this bit (ROIRQ) to clear it  
- 0b - No roll-over has occurred  
- 1b - Roll-over has occurred |
| ROIE | Roll-over Interrupt Enable read/write bit enables roll-over interrupts, based on Roll-under Interrupt Request (CTRL2[ROIRQ]) being set. This roll-over interrupt is combined with the index interrupt signal.  
- 0b - Disabled  
- 1b - Enabled |
| RUIRQ | Roll-under Interrupt Request bit is set (=1) when the position counter (POS) rolls under from the INIT value to the MOD value, or from 0x0000_0000 to 0xFFFF_FFFF.  
- Roll-under Interrupt Request will remain set until cleared by software  
- Write a one to this bit (RUIRQ) to clear it  
- 0b - No roll-under has occurred  
- 1b - Roll-under has occurred |
| RUIE | Roll-under Interrupt Enable read/write bit enables roll-under interrupts, based on the Roll-over Interrupt Request bit (CTRL2[RUIRQ]) being set. This roll-under interrupt is combined with the index interrupt signal.  
- 0b - Disabled  
- 1b - Enabled |
| DIR | Count Direction Flag indicates the direction of the last count.  
- 0b - Last count was in the down direction  
- 1b - Last count was in the up direction |
| MOD | Enable Modulo Counting  
- When Enable Modulo Counting is set (=1), it allows the position counters (UPOS and LPOS) to count in a modulo fashion, using MOD and INIT as the upper and lower bounds of the counting range. During modulo counting:  
*Table continues on the next page...*
<table>
<thead>
<tr>
<th>Field</th>
<th>Function</th>
</tr>
</thead>
</table>
| UPDPOS | Update Position Registers  
  - When Update Position Registers is set (=1), it allows the TRIGGER input to clear the POSD, REV, UPOS, and LPOS registers  
  - When Update Position Registers is clear (=0), the POSD, REV, UPOS, and LPOS registers ignore the TRIGGER input |
| UPDHL | Update Hold Registers  
  - When Update Hold Registers is set (=1), it allows the TRIGGER input to cause an update of the POSDH, REVH, UPOSH, and LPOSH registers  
  - When Update Hold Registers is clear (=0), the hold registers (POSDH, REVH, UPOSH, LPOSH) are not updated by the TRIGGER input |

Updating the Position Difference Hold Register (POSDH) will also cause the Position Difference Counter Register (POSD) to be cleared.  
0b - Disable updates of hold registers on the rising edge of TRIGGER input signal  
1b - Enable updates of hold registers on the rising edge of TRIGGER input signal

57.2 Overview

The Watchdog Timer (WDOG) protects against system failures by providing a method by which to escape from unexpected events or programming errors.

Once the WDOG is activated, it must be serviced by the software on a periodic basis. If servicing does not take place, the timer times out. Upon timeout, the WDOG1 asserts the internal system reset signal, WDOG_RESET_B_DEB to the System Reset Controller (SRC); and WDOG2 asserts interrupt to SNVS, to report the security violation condition.

There is also a provision for WDOG(ipp_wdog) signal assertion by timeout counter expiration. There is an option of programmable interrupt generation before the counter actually times out. The time at which the interrupt needs to be generated prior to counter...
timeout is programmable. There is a power down counter which is enabled out of any reset (POR, Warm/Cold). This counter has a fixed timeout period of 16 seconds, upon which it asserts the WDOG(ipp_wdog) signal.

Flow diagrams for the timeout counter, power down counter and interrupt operations are shown in Flow Diagrams.

**Figure 57-1. WDOG Diagram**

**NOTE**
WDOG-1 means WDOG_B when it presents on a PAD.

### 57.2.1 Features

The WDOG features are listed below:

- Configurable timeout counter with timeout periods from 0.5 to 128 seconds which, after timeout expiration, result in the assertion of WDOG_RESET_B_DEB reset signal.
- Time resolution of 0.5 seconds
- Configurable timeout counter that can be programmed to run or stop during low-power modes
• Configurable timeout counter that can be programmed to run or stop during DEBUG mode
• Programmable interrupt generation prior to timeout
• The duration between interrupt and timeout events can be programmed from 0 to 127.5 seconds in steps of 0.5 seconds.
• Power down counter with fixed timeout period of 16 seconds, which if not disabled after reset will assert WDOG_B (ipp_wdog) signal low
  • Power down counter will be enabled out of any reset (POR, Warm / Cold reset) by default.

57.3 External signals

See more detailed information in the Pin MUX chapter.

57.4 Clocks

This section describes clocks and special clocking requirements of the block.

The WDOG uses the low frequency reference clock for its counter and control operations. The peripheral bus clock is used for register read/write operations.

The following table describes the clock sources for WDOG. Please see for clock setting, configuration and gating information.
### Table 57-3. WDOG Clocks

### 57.5 Watchdog mechanism and system integration

The WDOG1 module and the WDOG2 (TZ) module are disabled by default (after reset). WDOG1 will be configured during boot while WDOG2 is dedicated for secure world purposes and will be activated by TZ software if required. The TZ watchdog (WDOG2) module protects against TZ starvation by providing a method of escaping normal mode and forcing a switch to the TZ mode. TZ starvation is a situation where the normal OS prevents switching to the TZ mode. Such a situation is undesirable as it can compromise the system’s security.

Once the TZ WDOG module is activated, it must be serviced by TZ on a periodic basis. If servicing does not take place, the timer times out. Upon a timeout, the TZ WDOG asserts a TZ-mapped interrupt that forces switching to the TZ mode. If it is still not serviced, the TZ WDOG asserts a security violation signal to the CSU. The TZ WDOG module cannot be programmed or de-activated by normal mode software.

The WDOG modules operate as follows:
- If servicing does not take place, the timer times out and the wdog_rst_b signal is activated (low)
- Interrupt can be generated before the counter actually times out
- The wdog_rst_b signal can be activated by software
- There is a power-down counter which gets enabled out of any reset. This counter has a fixed timeout period of 16 seconds upon which it will assert the ipp_wdog_b signal.

### 57.6 Functional description

This section provides a complete functional description of the block.
57.6.1 Timeout event

The WDOG provides timeout periods from 0.5 to 128 seconds with a time resolution of 0.5 seconds.

The user can determine the timeout period by writing to the WDOG timeout field (WT[7:0]) in the Watchdog Control (WCR). The WDOG must be enabled by setting the WDE bit of Watchdog Control (WCR) for the timeout counter to start running. After the WDOG is enabled, the counter is activated, loads the timeout value and begins to count down from this programmed value. The timer will time out when the counter reaches zero and the WDOG outputs a system reset signal, WDOG_RESET_B_DEB and asserts WDOG_B (ipp_wdog) (WDT bit should be set in Watchdog Control (WCR)).

However, the timeout condition can be prevented by reloading the counter with the new timeout value (WT[7:0] of WDOG_WCR) if a service routine (see Servicing WDOG to reload the counter) is performed before the counter reaches zero. If any system errors occur which prevent the software from servicing the Watchdog Service (WSR), the timeout condition occurs. By performing the service routine, the WDOG reloads its counter to the timeout value indicated by bits WT[7:0] of the Watchdog Control (WCR) and it restarts the countdown.

A system reset will reset the counter and place it in the idle state at any time during the countdown. The counter flow diagram is shown in Flow Diagrams.

NOTE

The timeout value is reloaded to the counter either at the time WDOG is enabled or after the service routine has been performed.

57.6.1.1 Servicing WDOG to reload the counter

To reload a timeout value to the counter the proper service sequence begins by writing 0x_5555 followed by 0x_AAAA to the Watchdog Service (WSR). Any number of instructions can be executed between the two writes. If the WDOG_WSR is not loaded with 0x_5555 prior to writing 0x_AAAA to the WDOG_WSR, the counter is not reloaded. If any value other than 0x_AAAA is written to the WDOG_WSR after 0x_5555, the counter is not reloaded. This service sequence will reload the counter with the timeout value WT[7:0] of Watchdog Control (WCR). The timeout value can be changed at any point; it is reloaded when WDOG is serviced by the core.
57.6.2 Interrupt event

Prior to timeout, the WDOG can generate an interrupt which can be considered a warning that timeout will occur shortly.

The duration between interrupt event and timeout event can be controlled by writing to the WICT field of Watchdog Interrupt Control (WICR). It can vary between 0 and 127.5 seconds. If the WDOG is serviced (Servicing WDOG to reload the counter) before the interrupt generation, the counter will be reloaded with the timeout value WT[7:0] of Watchdog Control (WCR) and the interrupt will not be triggered.

57.6.3 Power-down counter event

The power-down counter inside WDOG will be enabled out of reset. This counter has a fixed timeout value of 16 seconds, after which it will drive the WDOG_B (ipp_wdog) signal low.

To prevent this, the software must disable this counter by clearing the PDE bit of Watchdog Miscellaneous Control (WMCR) within 16 seconds of reset deassertion. Once disabled, this counter can't be enabled again until the next system reset occurs. This feature is intended to prevent the hanging up of cores after reset, as WDOG is not enabled out of reset.

57.6.4 Low power modes

57.6.4.1 STOP and DOZE mode

If the WDOG timer disable bit for low power STOP and DOZE mode (WDZST) bit in the Watchdog Control (WCR), is cleared, the WDOG timer continues to operate using the low frequency reference clock. If the low power enable (WDZST) bit is set, the WDOG timer operation will be suspended in low power STOP or DOZE mode. Upon exiting low power STOP or DOZE mode, the WDOG operation returns to what it was prior to entering the STOP or DOZE mode.
57.6.4.2 WAIT mode

If the WDOG timer disable bit for low power WAIT mode (WDW) bit in the Watchdog Control (WCR), is cleared, the WDOG timer continues to operate using the low frequency reference clock i.e ipg_clk_32k clock (32.768 kHz frequency clock). If the low power WAIT enable (WDW) bit is set, the WDOG timer operation will be suspended. Upon exiting low power WAIT mode, the WDOG operation returns to what it was prior to entering the WAIT mode.

NOTE
The WDOG timer won't be able to detect events that happen for periods shorter than one low frequency reference clock cycle. For example, in repeated WAIT mode entry or exit, if the RUN mode time is less than one low frequency reference clock cycle and if the WDW bit is set, the WDOG timer may never time out, even though the system is in RUN mode for a finite duration; WDOG may not see a low frequency reference clock edge during its wake time.

57.6.5 Debug mode

The WDOG timer can be configured for continual operation, or for suspension during debug mode. If the WDOG debug enable (WDBG) bit is set in the Watchdog Control (WCR), the WDOG timer operation is suspended in debug mode. If the WDBG bit is set and the debug mode (ipg_debug signal assertion) is entered, WDOG timer operation is suspended after two low frequency reference (ipg_clk_32k) clocks. Similarly, WDOG timer operation continues after two low frequency reference clocks of debug mode exit. Register read and write accesses in debug mode continue to function normally. Also, while in debug mode, the WDE bit of Watchdog Control (WCR) can be enabled/disabled directly. If the WDOG debug enable (WDBG) bit is cleared then WDOG timer operation is not suspended. The power-down counter is not affected by debug mode entry/exit.

NOTE
If the WDE bit of Watchdog Control (WCR) is set/cleared while in debug mode, it remains set/cleared even after exiting debug mode.

57.6.6 Operations
57.6.6.1 Watchdog reset generation

The WDOG generated reset signal WDOG_RESET_B_DEB is asserted by the following operations:

- A software write to the Software Reset Signal (SRS) bit of the Watchdog Control (WCR).
- WDOG timeout. See Timeout event.

The wdog_rst will be asserted for one clock cycle of low frequency reference clock for both a timeout condition and a software write occurrence. It remains asserted for 1 clock cycle of low frequency reference clock even if a system reset is asserted in between. Figure 57-3 shows the timing diagram of this signal due to a timeout condition.

57.6.6.2 WDOG_B generation

The WDOG asserts WDOG_B in the following scenarios:

- Software write to WDA bit of Watchdog Control (WCR). WDOG_B signal remains asserted as long as the WDA bit is "0".
- WDOG timeout condition, WDT bit of Watchdog Control (WCR) must be set for this scenario. A description of the timeout condition can be found in the Timeout event. WDOG_B (ipp_wdog) signal remains asserted until a power-on reset (POR) occurs. It gets cleared after the POR occurs (not due to any other system reset). Figure 57-4 shows the timing diagram of WDOG_B (ipp_wdog) due to timeout condition.
- WDOG power-down counter timeout, PDE bit of Watchdog Miscellaneous Control (WMCR) should not be cleared for this scenario. A description of this counter can be found in the Power-down counter event. WDOG_B (ipp_wdog) signal remains asserted for one clock cycle of low frequency reference clock (ipg_clk_32k).

Figure 57-2 shows the scenarios under which WDOG_B(ipp_wdog) gets asserted.

Figure 57-3. WDOG timeout condition/WDT bit is not set
Functional description

57.6.7 Reset

The block is reset by a system reset and the WDOG counter will be disabled. The power-down counter is enabled and starts counting.

57.6.8 Interrupt

The WDOG has the feature of Interrupt generation before timeout.

The interrupt will be generated only if the WIE bit in Watchdog Interrupt Control (WICR) is set. The exact time at which the interrupt should occur (prior to timeout) depends on the value of WICT field of Watchdog Interrupt Control (WICR). For example, if the WICT field has a value 0x04, then the interrupt will be generated two seconds prior to timeout. Once the interrupt is triggered the WTIS bit in Watchdog Interrupt Control (WICR) will be set. The software needs to clear this bit to deassert the interrupt. If the WDOG is serviced before the interrupt generation then the counter will be reloaded with the timeout value WT[7:0] of Watchdog Control (WCR) and interrupt would not be triggered.
57.6.9 Flow Diagrams

A flow diagram of WDOG operation is shown below.

![Flow Diagram of WDOG Operation](image)

Figure 57-5. Power-Down Counter Flow Diagram
57.7 Initialization

The following sequence should be performed for WDOG initialization.

- PDE bit of Watchdog Miscellaneous Control (WMCR) should be cleared to disable the power down counter.
• WT field of **Watchdog Control (WCR)** should be programmed for sufficient timeout value.
• WDOG should be enabled by setting WDE bit of **Watchdog Control (WCR)** so that the timeout counter loads the WT field value of **Watchdog Control (WCR)** and starts counting.

## 57.8  WDOG Memory Map/Register Definition

### 57.8.1  WDOG Register Descriptions

The WDOG has user-accessible, 16-bit registers used to configure, operate, and monitor the state of the Watchdog Timer. Byte operations can be performed on these registers. If a 32-bit access is performed, the WDOG will not generate a peripheral bus error but will behave normally, like a 16-Bit access, making read/write possible. A 32-Bit access should be avoided, as the system may go to an unknown state.

### 57.8.1.1  WDOG Memory Map

WDOG1 base address: 400B_8000h.
WDOG2 base address: 400D_0000h.

57.8.1.2.2 Function

The Watchdog Control Register (WDOG_WCR) controls the WDOG operation.

- WDZST, WDBG and WDW are write-once only bits. Once the software does a write access to these bits, they will be locked and cannot be reprogrammed until the next system reset assertion.
- WDE is a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next system reset.
- WDT is also a write one once only bit. Once software performs a write "1" operation to this bit it cannot be reset/cleared until the next POR. This bit does not get reset/cleared due to any system reset.

<td>4h</td>
</tr>
</tbody>
</table>

57.8.1.4.2 Function

The WRSR is a read-only register that records the source of the output reset assertion. It is not cleared by a hard reset. Therefore, only one bit in the WRSR will always be asserted high. The register will always indicate the source of the last reset generated due to WDOG. Read access to this register is with one wait state. Any write performed on this register will generate a Peripheral Bus Error.

A reset can be generated by the following sources, as listed in priority from highest to lowest:

- Watchdog Time-out
- Software Reset

NOTE

On this device, both LPO clock and INTCLK are 32 KHz clock generated by 32 KHz XTAL, which could be automatically switched to 32 KHz RCOSC upon XTAL clock loss. ERCLK is 1 MHz RCOSC clock generated by ANATOP.

58.2 Introduction

The Watchdog Timer (WDOG) module is an independent timer that is available for system use. It provides a safety feature to ensure that software is executing as planned and that the CPU is not stuck in an infinite loop or executing unintended code. If the WDOG module is not serviced (refreshed) within a certain period, it resets the MCU.
58.2.1 Features

Features of the WDOG module include:

- Configurable clock source inputs independent from the bus clock
  - Bus clock (slow clock)
  - LPO clock
  - INTCLK (internal clock)
  - ERCLK (external reference clock)

- Programmable timeout period
  - Programmable 16-bit timeout value
  - Optional fixed 256 clock prescaler when longer timeout periods are needed

- Robust write sequence for counter refresh
  - Refresh sequence of writing 0xA602 and then 0xB480

- Window mode option for the refresh mechanism
  - Programmable 16-bit window value
  - Provides robust check that program flow is faster than expected
  - Early refresh attempts trigger a reset.

- Optional timeout interrupt to allow post-processing diagnostics
  - Interrupt request to CPU with interrupt vector for an interrupt service routine (ISR)
  - Forced reset occurs 255 bus clocks after the interrupt vector fetch.

- Configuration bits are write-once-after-reset to ensure watchdog configuration cannot be mistakenly altered.

- Robust write sequence for unlocking write-once configuration bits
  - Unlock sequence of writing 0xC520 and then 0xD928 for allowing updates to write-once configuration bits
  - Software must make updates within 255 bus clocks after unlocking and before WDOG closing unlock window.
58.2.2 Block diagram

The following figure shows a block diagram of the WDOG module.

![Figure 58-1. WDOG block diagram](image-url)

58.3 Functional description

The WDOG module provides a fail safe mechanism to ensure the system can be reset to a known state of operation in case of system failure, such as the CPU clock stopping or there being a run away condition in the software code. The watchdog counter runs continuously off a selectable clock source and expects to be serviced (refreshed) periodically. If it is not, it generates a reset triggering event.

The timeout period, window mode, and clock source are all programmable but must be configured within 255 bus clocks after a reset.

58.3.1 Clock source

The watchdog counter has the following clock source options selected by programming CS[CLK]:

- bus clock
- Low-Power Oscillator clock (LPO_CLK) (This is the default source.)
The options allow software to select a clock source independent of the bus clock for applications that need to meet more robust safety requirements. Using a clock source other than the bus clock ensures that the watchdog counter continues to run if the bus clock is somehow halted; see Backup reset.

An optional fixed prescaler for all clock sources allows for longer timeout periods. When CS[PRES] is set, the clock source is prescaled by 256 before clocking the watchdog counter.

The following table summarizes the different watchdog timeout periods which could be available, as an example.

<table>
<thead>
<tr>
<th>Reference clock</th>
<th>Prescaler</th>
<th>Watchdog time-out availability</th>
</tr>
</thead>
<tbody>
<tr>
<td>LPO_CLK</td>
<td>Pass through</td>
<td>~1 ms–65.5 s (if LPO_CLK = 1 kHz); (~1 ms–65.5 s)/128 (if LPO_CLK = 128 kHz). 1</td>
</tr>
<tr>
<td>256</td>
<td></td>
<td>~256 ms–16,777.2 s (if LPO_CLK = 1 kHz); ~2 ms–131.1 s (if LPO_CLK = 128 kHz).</td>
</tr>
<tr>
<td>Internal clock 8 MHz</td>
<td>Pass through</td>
<td>125 ns–8.1925 ms</td>
</tr>
<tr>
<td>256</td>
<td></td>
<td>32 µs–2.09728 s</td>
</tr>
<tr>
<td>1 MHz (from bus or external)</td>
<td>Pass through</td>
<td>1 µs–65.54 ms</td>
</tr>
<tr>
<td>256</td>
<td></td>
<td>256 µs–16.777 s</td>
</tr>
<tr>
<td>20 MHz (from bus or external)</td>
<td>Pass through</td>
<td>50 ns–3.277 ms</td>
</tr>
<tr>
<td>256</td>
<td></td>
<td>12.8 µs–838.8 ms</td>
</tr>
</tbody>
</table>

1. The default timeout value after reset is approximately 32000 ms (if LPO_CLK = 1 kHz), or 32000/128 ms (if LPO_CLK = 128 kHz).

NOTE
When the programmer switches clock sources during reconfiguration, the watchdog hardware holds the counter at zero for 2.5 periods of the previous clock source and 2.5 periods of the new clock source after the configuration time period (255 bus clocks) ends. This delay ensures a smooth transition before restarting the counter with the new configuration.

58.3.2 Watchdog refresh mechanism

The watchdog resets the MCU if the watchdog counter is not refreshed. A robust refresh mechanism makes it very unlikely that the watchdog can be refreshed by runaway code.
To refresh the watchdog counter, software must execute a refresh write sequence before the timeout period expires. In addition, if window mode is used, software must not start the refresh sequence until after the time value set in the WIN register. See the following figure.

**Figure 58-2. Refresh opportunity for the Watchdog counter**

58.3.2.1 Window mode

Software finishing its main control loop faster than expected could be an indication of a problem. Depending on the requirements of the application, the WDOG can be programmed to force a reset when refresh attempts are early.

When Window mode is enabled, the watchdog must be refreshed after the counter has reached a minimum expected time value; otherwise, the watchdog resets the MCU. The minimum expected time value is specified in the WIN register. Setting CS[WIN] enables Window mode.
58.3.2.2 Refreshing the Watchdog

The refresh write sequence can be
• either two 16-bit writes (0xA602, 0xB480) or four 8-bit writes (0xA6, 0x02, 0xB4, 0x80; applicable to Cortex-M core cases) if WDOG_CS[CMD32EN] is 0;
• one 32-bit write (0xB480_A602) if WDOG_CS[CMD32EN] is 1.

to the CNT register. Both methods must occur before the WDG timeout; otherwise, the watchdog resets the MCU.

Note
Before starting the refresh sequence, disable the global interrupts. Otherwise, an interrupt could effectively invalidate the refresh sequence, if the interrupt occurs before the refresh writes finish. After the sequence finishes, restore the global interrupt control state.

The example codes can be found at the end of this chapter.

58.3.3 Configuring the Watchdog

58.3.3.1 Configuring the Watchdog Once

All watchdog control bits, timeout value, and window value are write-once after reset within 255 bus clocks. This means that after a write has occurred they cannot be changed unless a reset occurs. This is guaranteed by the user configuring the window and timeout value first, followed by the other control bits, and ensuring that CS[UPDATE] is also set to 0.

This provides a robust mechanism to configure the watchdog and ensure that a runaway condition cannot mistakenly disable or modify the watchdog configuration after configured.

The new configuration takes effect only after all registers except CNT are written after reset. Otherwise, the WDOG uses the reset values by default. If window mode is not used (CS[WIN] is 0), writing to WIN is not required to make the new configuration take effect.

58.3.3.2 Reconfiguring the Watchdog

In some cases (like when supporting a bootloader function), you may want to reconfigure or disable the watchdog, without forcing a reset first.
• By setting CS[UPDATE] to 1 on the initial configuration of the watchdog after a reset, you can reconfigure the watchdog at any time by executing an unlock sequence.
• Conversely, if CS[UPDATE] remains 0, the only way to reconfigure the watchdog is by initiating a reset.

The unlock sequence is similar to the refresh sequence but uses different values.

58.3.3.2 Unlocking the Watchdog

The unlock sequence is a write to the CNT register of 0xC520 followed by 0xD928 within 31 bus clocks at any time after the watchdog has been configured. On completing the unlock sequence, the user must reconfigure the watchdog within 255 bus clocks; otherwise, the watchdog closes the unlock window.

NOTE
Due to the 255 bus clocks requirement for reconfiguring the watchdog, some delays must be inserted before executing STOP or WAIT instructions after reconfiguring the watchdog. This ensures that the watchdog's new configuration takes effect before the MCU enters low power mode. Otherwise, watchdog will not be able to wake the MCU from low power mode.

The example codes can be found at end of this chapter.

58.3.4 Using interrupts to delay resets

• When interrupts are enabled (CS[INT] = 1): After a reset-triggering event (like a counter timeout or invalid refresh attempt), the watchdog first generates an interrupt request. Next, the watchdog delays 255 bus clocks (from the interrupt vector fetch, not the reset-triggering event) before forcing a reset, to allow the interrupt service routine (ISR) to perform tasks (like analyzing the stack to debug code).
• When interrupts are disabled (CS[INT] = 0): the watchdog does not delay the forcing a reset.

58.3.5 Backup reset

NOTE
A clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the backup reset function is not available.
The backup reset function is a safeguard feature that independently generates a reset in case the main WDOG logic loses its clock (the bus clock) and can no longer monitor the counter. If the watchdog counter overflows twice in succession (without an intervening reset), the backup reset function takes effect and generates a reset.

Backup reset becomes valid when interrupt is enabled and the watchdog clock is from non bus clock. If interrupt is enabled, once the bus clock is cut off before exiting interrupt routine, the normal watchdog reset will be blocked. Under this case, the second overflow will cause backup reset directly.

58.3.6 Functionality in debug and low-power modes

By default, the watchdog is not functional in Debug mode, Wait mode, or Stop mode. However, the watchdog can remain functional in these modes as follows:

- **For Debug mode**, set CS[DBG]. (This way the watchdog is functional in Debug mode even when the CPU is held by the Debug module.)
- **For Wait mode**, set CS[WAIT].
- **For Stop mode**, set CS[STOP], CS[WAIT], and ensure the clock source is active in Stop mode.

**NOTE**

The watchdog can generate interrupt in Stop mode.

For Debug mode and Stop mode, in addition to the above configurations, a clock source other than the bus clock must be used as the reference clock for the counter; otherwise, the watchdog cannot function.

58.3.7 Fast testing of the watchdog

Before executing application code in safety critical applications, users are required to test that the watchdog works as expected and resets the MCU. Testing every bit of a 16-bit counter by letting it run to the overflow value takes a relatively long time (64 kHz clocks).

To help minimize the startup delay for application code after reset, the watchdog has a feature to test the watchdog more quickly by splitting the counter into its constituent byte-wide stages. The low and high bytes are run independently and tested for timeout against the corresponding byte of the timeout value register. (For complete coverage
when testing the high byte of the counter, the test feature feeds the input clock via the 8th bit of the low byte, thus ensuring that the overflow connection from the low byte to the high byte is tested.)

Using this test feature reduces the test time to 512 clocks (not including overhead, such as user configuration and reset vector fetches). To further speed testing, use a faster clock (such as the bus clock) for the counter reference.

On a power-on reset, the POR bit in the system reset register is set, indicating the user should perform the WDOG fast test.

### 58.3.7.1 Testing each byte of the counter

The test procedure follows these steps:

1. Program the preferred watchdog timeout value in the TOVAL register during the watchdog configuration time period.
2. Select a byte of the counter to test using the CS[TST] = 10b for the low byte; CS[TST] = 11b for the high byte.
3. Wait for the watchdog to timeout. Optionally, in the idle loop, increment RAM locations as a parallel software counter for later comparison. Because the RAM is not affected by a watchdog reset, the timeout period of the watchdog counter can be compared with the software counter to verify the timeout period has occurred as expected.
4. The watchdog counter times out and forces a reset.
5. Confirm the WDOG flag in the system reset register is set, indicating that the watchdog caused the reset. (The POR flag remains clear.)
6. Confirm that CS[TST] shows a test (10b or 11b) was performed.

If confirmed, the count and compare functions work for the selected byte. Repeat the procedure, selecting the other byte in step 2.

**NOTE**

CS[TST] is cleared by a POR only and not affected by other resets.

### 58.3.7.2 Entering user mode

After successfully testing the low and high bytes of the watchdog counter, the user can configure CS[TST] to 01b to indicate the watchdog is ready for use in application user mode. Thus if a reset occurs again, software can recognize the reset trigger as a real watchdog reset caused by runaway or faulty application code.
As an ongoing test when using the default LPO clock source, software can periodically read the CNT register to ensure the counter is being incremented.

58.4 Application Information

The watchdog is enabled by default after reset. To disable or reconfigure the watchdog, it is better to be done before the first watchdog timeout. It is suggested to disable or reconfigure the watchdog at the very beginning of the software code, e.g. beginning of the startup or main function.

NOTE
When the watchdog is configured by user, it needs at least 2.5 periods of watchdog clock to take effect. This means interval between two configures by user must be larger than 2.5 clocks.

NOTE
When Chip startup from BOOT ROM then jump to flash, the watchdog would be enabled in the beginning of bootloader, and disabled when bootloader exits. If there is any code in the flash program want to reconfigure the watchdog, it must be run 2.5 watchdog clocks later after the bootloader exits.

To disable or reconfigure the watchdog without forcing a reset, WDOG_CS[UPDATE] bit must be set during the initial configuration of the WDOG module. Then, the unlock sequence can be used at any time within the timeout limit to reconfigure the watchdog.

58.4.1 Disable Watchdog

To disable the watchdog, first do unlock sequence, then unset the WDOG_CS[EN] bit. The code snippet below shows an example for 32-bit write.

```
DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; //unlock watchdog
WDOG_CS &= ~WDOG_CS_EN_MASK; //disable watchdog
EnableInterrupts; //enable global interrupt
```

58.4.2 Configure Watchdog

The watchdog can be configured once by set the WDOG_CS[UPDATE]=0. After that, the watchdog cannot be reconfigured until a reset. If set WDOG_CS[UPDATE]=1 when configuring the watchdog, the watchdog can be reconfigured without forcing a reset. The
following example code shows how to configure the watchdog without window mode, clock source as LPO, interrupt enabled and timeout value to 256 clocks. The code snippet below shows an example for 32-bit write.

**Configure once**

DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; // unlock watchdog
while(WDOG_CS[ULK]==0); // wait until registers are unlocked
WDOG_TOVAL = 256; // set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) | WDOG_CS_WIN(0) | WDOG_CS_UPDATE(0);
while(WDOG_CS[RCS]==0); // wait until new configuration takes effect
EnableInterrupts; // enable global interrupt

**Configure for reconfigurable**

DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xD928C520; // unlock watchdog
while(WDOG_CS[ULK]==0); // wait until registers are unlocked
WDOG_TOVAL = 256; // set timeout value
WDOG_CS = WDOG_CS_EN(1) | WDOG_CS_CLK(1) | WDOG_CS_INT(1) | WDOG_CS_WIN(0) | WDOG_CS_UPDATE(1);
while(WDOG_CS[RCS]==0); // wait until new configuration takes effect
EnableInterrupts; // enable global interrupt

### 58.4.3 Refreshing the Watchdog

To refresh the watchdog and reset the watchdog counter to zero, a refresh sequence is required. The code snippet below shows an example for 32-bit write.

DisableInterrupts; // disable global interrupt
WDOG_CNT = 0xB480A602; // refresh watchdog
EnableInterrupts; // enable global interrupt

### 58.5 Memory map and register definition

#### 58.5.1 WDOG Register Descriptions

#### 58.5.1.1 WDOG Memory Map

WDOG3 (RTWDOG) base address: 400B_C000h
This section describes the function of Watchdog Control and Status Register.

### NOTE
TST is cleared (0:0) on POR only. Any other reset does not affect the value of this field.

58.5.1.3.2 Function

This section describes the watchdog counter register.

The watchdog counter register provides access to the value of the free-running watchdog counter. Software can read the counter register at any time.
Software cannot write directly to the watchdog counter; however, two write sequences to these registers have special functions:

1. The refresh sequence resets the watchdog counter to 0x0000. See the "Refreshing the Watchdog" section.
2. The unlock sequence allows the watchdog to be reconfigured without forcing a reset (when CS[UPDATE] = 1). See the "Configure for reconfigurable" section.

**NOTE**
All other writes to this register are illegal and force a reset.

<td>8h</td>
</tr>
</tbody>
</table>
58.5.1.4.2  Function

This section describes the watchdog timeout value register. TOVAL contains the 16-bit value used to set the timeout period of the watchdog.

The watchdog counter (CNT) is continuously compared with the timeout value (TOVAL). If the counter reaches the timeout value, the watchdog forces a reset triggering event.

NOTE

Do not write 0 to the Watchdog Timeout Value Register; otherwise, the watchdog always generates a reset.

For low power clock source, see lpo_clk[3:0] in the EWM Signal Descriptions table.

**NOTE**

- lpo_clk[0] is 32 kHz clock generated by 32 kHz XTAL, which could be automatically switched to 32 kHz RCOSC upon XTAL clock loss;
- lpo_clk[1] is 1 MHz RCOSC clock generated by ANATOP;
- lpo_clk[3:2] are not used on this device.
59.2 Introduction

For safety, a redundant watchdog system, External Watchdog Monitor (EWM), is designed to monitor external circuits, as well as the MCU software flow. This provides a back-up mechanism to the internal watchdog that resets the MCU’s CPU and peripherals.

The watchdog is generally used to monitor the flow and execution of embedded software within an MCU. The watchdog consists of a counter that if allowed to overflow, forces an internal reset (asynchronous) to all on-chip peripherals and optionally assert the RESET_B pin to reset external devices/circuits. The overflow of the watchdog counter must not occur if the software code works well and services the watchdog to re-start the actual counter.

The EWM differs from the internal watchdog in that it does not reset the MCU's CPU and peripherals. The EWM provides an independent EWM_OUT_B signal that when asserted resets or places an external circuit into a safe mode. The EWM_OUT_B signal is asserted upon the EWM counter time-out. An optional external input EWM_in is provided to allow additional control of the assertion of EWM_OUT_B signal.

59.2.1 Features

Features of EWM module include:

- Independent LPO_CLK clock source
- Programmable time-out period specified in terms of number of EWM LPO_CLK clock cycles.
- Windowed refresh option
  - Provides robust check that program flow is faster than expected.
  - Programmable window.
  - Refresh outside window leads to assertion of EWM_OUT_B.
- Robust refresh mechanism
  - Write values of 0xB4 and 0x2C to EWM Refresh Register within 23 peripheral bus clock cycles.
• One output port, EWM_OUT_B, when asserted is used to reset or place the external circuit into safe mode.

• One Input port, EWM_in, allows an external circuit to control the assertion of the EWM_OUT_B signal.

59.2.2 Modes of Operation

This section describes the module's operating modes.

59.2.2.1 Stop Mode

When the EWM is in stop mode, the CPU refreshes to the EWM cannot occur. On entry to stop mode, the EWM's counter freezes.

There are two possible ways to exit from Stop mode:

• On exit from stop mode through a reset, the EWM remains disabled.

• On exit from stop mode by an interrupt, the EWM is re-enabled, and the counter continues to be clocked from the same value prior to entry to stop mode.

Note the following if the EWM enters the stop mode during CPU refresh mechanism: At the exit from stop mode by an interrupt, refresh mechanism state machine starts from the previous state which means, if first refresh command is written correctly and EWM enters the stop mode immediately, the next command has to be written within the next 23 peripheral bus clocks after exiting from stop mode. User must mask all interrupts prior to executing EWM refresh instructions.

59.2.2.2 Wait Mode

The EWM module treats the stop and wait modes as the same. EWM functionality remains the same in both of these modes.

59.2.2.3 Debug Mode

Entry to debug mode has no effect on the EWM.
- If the EWM is enabled prior to entry of debug mode, it remains enabled.
- If the EWM is disabled prior to entry of debug mode, it remains disabled.

### 59.2.3 Block Diagram

This figure shows the EWM block diagram.

![EWM Block Diagram](image)

**Figure 59-1. EWM Block Diagram**

### 59.3 EWM Signal Descriptions

The EWM has two external signals and internal options for the counter clock sources, as shown in the following table.

```
<table>
<thead>

</tr>
</tbody>
</table>
```

**NOTE**

All active-low signals are now represented with the suffix ",_b" throughout the chapter.
59.4 Clocking

This table shows the EWM clocks.

<table>
<thead>
<tr>
<th>Clock</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ipg_clk</td>
<td>This is the system clock and must be running in order for the EWM to be able to work properly. During very low power modes in which the core is powered down, this clock is disabled.</td>
</tr>
<tr>
<td>ipg_clk_s</td>
<td>This is the IPS clock and is synchronous with ipg_clk.</td>
</tr>
<tr>
<td>lpo_clock[3:0]</td>
<td>EWM can have 4 different clock sources for running its EWM counter and one of them can be selected by EWM_CLKCTRL[CLK_SEL]. This clock is gated when EWM is disabled or when EWM_OUT_B is asserted.</td>
</tr>
</tbody>
</table>

59.5 Functional Description

The following sections describe functional details of the EWM module.

**NOTE**

When the BUS_CLK is lost, then EWM module doesn't generate the EWM_OUT_B signal and no refresh operation is possible.

59.5.1 The EWM_OUT_B Signal

The EWM_OUT_B is a digital output signal used to gate an external circuit (application specific) that controls critical safety functions. For example, the EWM_OUT_B could be connected to the high voltage transistors circuits that control an AC motor in a large appliance.

The EWM_OUT_B signal remains deasserted when the EWM is being regularly refreshed by the CPU within the programmable refresh window, indicating that the application code is executed as expected.
The EWM_OUT_B signal is asserted in any of the following conditions:

- The EWM refresh occurs when the counter value is less than CMPL value.
- The EWM counter value reaches the CMPH value, and no EWM refresh has occurred.
- If functionality of EWM_in pin is enabled and EWM_in pin is asserted while refreshing the EWM.
- After any reset (by the virtue of the external pull-down mechanism on the EWM_OUT_B pin)

The EWM_OUT_B is asserted after any reset by the virtue of the external pull-down mechanism on the EWM_OUT_B signal. Then, to deassert the EWM_OUT_B signal, set EWMEN bit in the CTRL register to enable the EWM.

If the EWM_OUT_B signal shares its pad with a digital I/O pin, on reset this actual pad defers to being an input signal. The pad state is controlled by the EWM_OUT_B signal only after the EWM is enabled by the EWMEN bit in the CTRL register.

**Note**

EWM_OUT_B pad must be in pull down state when EWM functionality is used and when EWM is under Reset.

### 59.5.2 EWM_OUT_B pin state in low power modes

During Wait, Stop and Power Down modes the EWM_OUT_B pin enters a high-impedance state. A user has the option to control the logic state of the pin using an external pull device or by configuring the internal pull device. When the CPU enters a Run mode from Wait or Stop recovery, the pin resumes its previous state before entering Wait or Stop mode. When the CPU enters Run mode from Power Down, the pin returns to its reset state.

### 59.5.3 The EWM_in Signal

The EWM_in is a digital input signal for safety status of external safety circuits, that allows an external circuit to control the assertion of the EWM_OUT_B signal. For example, in the application, an external circuit monitors a critical safety function, and if there is fault with safety function, the external circuit can then actively initiate the EWM_OUT_B signal that controls the gating circuit.
The EWM_in signal is ignored if the EWM is disabled, or if INEN bit of CTRL register is cleared, as after any reset.

On enabling the EWM (setting the CTRL[EWMEN] bit) and enabling EWM_in functionality (setting the CTRL[INEN] bit), the EWM_in signal must be in the deasserted state prior to the CPU start refreshing the EWM. This ensures that the EWM_OUT_B stays in the deasserted state; otherwise, the EWM_OUT_B output signal is asserted.

**Note**

The user must update the CMPH and CMPL registers prior to enabling the EWM. After enabling the EWM, the counter resets to zero, therefore the user shall provide a reasonable time after a power-on reset for the external monitoring circuit to stabilize. The user shall also ensure that the EWM_in pin is deasserted.

### 59.5.4 EWM Counter

It is an 8-bit ripple counter fed from a clock source that is independent of the peripheral bus clock source. As the preferred time-out is between 1 ms and 100 ms the actual clock source should be in the kHz range.

The counter is reset to zero after the CPU reset, or when EWM refresh action completes, or at counter overflow. The counter value is not accessible to the CPU.

### 59.5.5 EWM Compare Registers

The compare registers CMPL and CMPH are write-once after a CPU reset and cannot be modified until another CPU reset occurs.

The EWM compare registers are used to create a refresh window to refresh the EWM module.

It is illegal to program CMPL and CMPH with same value. In this case, as soon as counter reaches (CMPL + 1), EWM_OUT_B is asserted.
59.5.6  EWM Refresh Mechanism

Other than the initial configuration of the EWM, the CPU can only access the EWM by the EWM Service Register. The CPU must access the EWM service register with correct write of unique data within the windowed time frame as determined by the CMPL and CMPH registers for correct EWM refresh operation. Therefore, three possible conditions can occur:

<table>
<thead>
<tr>
<th>Condition</th>
<th>Mechanism</th>
</tr>
</thead>
<tbody>
<tr>
<td>An EWM refresh action completes when: CMPL &lt; Counter &lt; CMPH.</td>
<td>The software behaves as expected and the EWM counter is reset to zero. The EWM_OUT_B output signal remains in the deasserted state if, during the EWM refresh action, the EWM_in input has been in deasserted state.</td>
</tr>
<tr>
<td>An EWM refresh action completes when Counter &lt; CMPL</td>
<td>The software refreshes the EWM before the windowed time frame, the counter is reset to zero and the EWM_OUT_B output signal is asserted irrespective of the input EWM_in signal.</td>
</tr>
<tr>
<td>Counter value reaches CMPH prior to completion of EWM refresh action.</td>
<td>Software has not refreshed the EWM. The EWM counter is reset to zero and the EWM_OUT_B output signal is asserted irrespective of the input EWM_in signal.</td>
</tr>
</tbody>
</table>

59.5.7  EWM Interrupt

When EWM_OUT_B is asserted, an interrupt request is generated to indicate the assertion of the EWM reset out signal. This interrupt is enabled when CTRL[INTEN] is set. Clearing this bit clears the interrupt request but does not affect EWM_OUT_B. The EWM_OUT_B signal can be deasserted only by forcing a system reset.

59.5.8  Selecting the EWM counter clock

There are four possible low power clock sources for the EWM counter. Select one of the available clock sources by programming CLKCTRL[CLKSEL].

59.5.9  Counter clock prescaler

The EWM counter clock source can be prescaled by a clock divider, by programming CLKPRESCALER[CLK_DIV]. This divided clock is used to run the EWM counter.

**NOTE**

The divided clock used to run the EWM counter must be no more than half the frequency of the bus clock.
59.6 Memory Map/Register Definition

This section contains the module memory map and registers.

NOTE

EWM only supports 8-bit register access. 16-bit and 32-bit access are not possible.

<thead>
<tr>
<th>Register</th>
<th>Offset</th>
</tr>
</thead>
<tbody>
<tr>
<td>CMPH</td>
<td>3h</td>
</tr>
</tbody>
</table>

59.6.1.5.2  Function

The CMPH register is reset to 0xFF after a CPU reset. This provides a maximum of 256 clocks time, for the CPU to refresh the EWM counter.

**NOTE**

This register can be written only once after a CPU reset. Writing this register more than once generates a bus transfer error.
NOTE

The valid values for CMPH are up to 0xFE because the EWM counter never expires when CMPH = 0xFF. The expiration happens only if EWM counter is greater than CMPH.

Chapter 60
On Chip Cross Triggers Overview

60.1 Overview

This chip integrates an on-chip cross trigger network. The following diagram shows the cross trigger network of this device.

Figure 60-1. On-Chip Cross Trigger Network
60.1.1 Cross BAR (XBAR)

Each crossbar switch is an array of MUXes with shared inputs. Each mux output provides one output of the crossbar. The number of inputs and the number of MUXes/outputs is user configurable and registers are provided to select which of the shared inputs is routed to each output. The crossbar switches are used to reconfigure data paths between peripherals (peripheral output to peripheral input) as well as between peripherals and GPIO.

60.1.2 And-Or-Inverter (AOI)

The AOI module provides an universal Boolean function generator using a four term sum of products expression, with each product term containing true or complement values of the four selected inputs (A, B, C, D).
Chapter 61
Inter-Peripheral Crossbar Switch A (XBARA)

61.1 Chip-specific XBAR information

On this device, for XBAR1 (see the XBARA chapter), the number of inputs is 88, and the number of outputs is 132. For XBAR2 and XBAR3 (see the XBARB chapter), the number of inputs is 64, and the number of outputs is 16.

NOTE

The XBAR_INn and XBAR_OUTn signals (n=4 to 19) share the same IOs. The user needs to configure the corresponding IOMUXC_GPR_GPR6[IOMUXC_XBAR_DIR_SEL_n] bit to use either XBAR_IN or XBAR_OUT.

61.2 Introduction
61.2.1 Overview

This module implements an array of M N-input combinational muxes. All muxes share the same N inputs in the same order, but each mux has its own independent select field.

The intended application of this module is to provide a flexible crossbar switch function that allows any input (typically from external GPIO or internal module outputs) to be connected to any output (typically to external GPIO or internal module inputs) under user control. This is used to allow user configuration of data paths between internal modules and between internal modules and GPIO.

A subset of the muxes can be configured to support edge detection and either interrupt or DMA request generation based on detected signal edges on the mux output. This allows signal transitions on the signals feeding the crossbar to trigger interrupts or initiate data transfers via DMA into or out of other system modules.

61.2.2 Features

The XBAR module design includes these distinctive features:
- M identical N-input muxes with individual select fields.
- Edge detection with associated interrupt or DMA request generation for a subset of mux outputs.
- Memory mapped registers with IPBus interface for select and control fields.
- Register write protection input signal.

61.2.3 Modes of Operation

The XBAR module design operates in only a single mode of operation: Functional Mode. The various counting modes are detailed in Functional Mode.

61.2.4 Block Diagram

The block diagram for XBAR is shown in Figure 61-1.
Note: Control field support can be restricted to a subset of outputs. CTRLn represents the memory mapped control fields in the XBAR_CTRL registers for each corresponding XBAR_OUT output. Control fields provide edge status, edge selection, and interrupt/DMA generation controls.

Figure 61-1. XBAR Block Diagram

61.3 Signal Descriptions

The following table summarizes the module's external signals.

Table 61-2. Control Signal Properties

<table>
<thead>
<tr>
<th>Name</th>
<th>I/O Type</th>

</tr>
</tbody>
</table>
At reset, each output XBAR_OUT[*] contains the reset value of the signal driving XBAR_IN[0].

61.3.1 XBAR_OUT[0:NUM_OUT-1] - MUX Outputs

This is a one-dimensional array of the mux outputs. The value on each output XBAR_OUT[n] is determined by the setting of the corresponding memory mapped register SELn such that XBAR_OUT[n] = XBAR_IN[SELn].

61.3.2 XBAR_IN[0:NUM_IN-1] - MUX Inputs

This is a one-dimensional array consisting of the inputs shared by each mux. All muxes share the same inputs in the same order.

61.3.3 DMA_REQ[n] - DMA Request Output(s)

DMA_REQ[n] is a DMA request to the DMA controller.

61.3.4 DMA_ACK[n] - DMA Acknowledge Input(s)

DMA_ACK[n] is a DMA acknowledge input from the DMA controller.

61.3.5 INT_REQ[n] - Interrupt Request Output(s)

INT_REQ[n] is an interrupt request output to the interrupt controller.

61.4 Memory Map and Register Descriptions

The XBAR module has select registers and control registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBAR_IN[*]) is muxed to each mux output (XBAR_OUT[*]). There is one SELn field per mux and therefore one per XBAR_OUT output. Crossbar output XBAR_OUT[n]
presents the value of XBAR_IN[SELn]. Each select register contains two SELn fields. In the first select register, the LSBs contain the select field for mux 0, and the MSBs contain the select field for mux 1. The pattern repeats in subsequent select registers.

The actual signals connected to XBAR_IN and XBAR_OUT are application specific and are described in the Chip Configuration details.

The XBAR control registers configure edge detection, interrupt, and DMA features for a subset of the XBAR_OUT[*] outputs.

### 61.5 Functional Description

#### 61.5.1 General

The XBAR module has only one mode of operation, functional mode.

#### 61.5.2 Functional Mode

The value of each mux output is XBAR_OUT[n] = XBAR_IN[SELn]. The SELn select values are configured in the XBAR_SEL registers. All muxes share the same inputs in the same order.

A subset of XBAR_OUT[*] outputs has dedicated control fields in a Crossbar Control (XBAR_CTRL) register. Control fields provide the ability to perform edge detection on the corresponding XBAR_OUT output. Edge detection in turn can optionally be used to trigger an interrupt or DMA request. The intention is that, by detecting specified edges on signals propagating through the Crossbar, interrupts or DMA requests can be triggered to perform data transfers to or from other system components.

Control fields include an edge status field (STS), an detected edge type field (EDGE), and interrupt and DMA enable fields (DEN and IEN). STSn is set to 1 when an edge consistent with EDGEn occurs on XBAR_OUT[n]. STSn is cleared by writing 1 to it. Writing 0 as no effect. See Interrupts and DMA Requests for details on the use of STSn for DMA and interrupt request generation.
61.6 Resets
The XBAR module can be reset by only a hard reset, which forces all registers to their reset state.

61.7 Clocks
All sequential functionality is controlled by the Bus Clock.

61.8 Interrupts and DMA Requests
For each XBAR_OUT[*] output with XBAR_CTRL register support, DMA or interrupt functionality can be enabled by setting the corresponding XBAR_CTRL register bit DENn or IENn to 1. DENn and IENn should not be set to 1 at the same time for the same output XBAR_OUT[n].

Setting DENn to 1 enables DMA functionality for XBAR_OUT[n]. When DMA functionality is enabled, the output DMA_REQ[n] reflects the value of STSn. Thus the DMA request asserts when the edge specified by EDGEn is detected on XBAR_OUT[n]. Also, a rising edge on DMA_ACK[n] sets STSn to zero and thus clears the DMA request. When DEN is 0, DMA_REQ[n] is held low and DMA_ACK[n] is ignored.

Setting IENn to 1 enables interrupt functionality for XBAR_OUT[n]. When interrupt functionality is enabled, the output INT_REQ[n] reflects the value of STSn. Thus the interrupt request asserts when the edge specified by EDGEIEn is detected on XBAR_OUT[n]. The interrupt request is cleared by writing a 1 to STSn. When IENn is 0, INT_REQ[n] is held low.

DENn and IENn should not be set to 1 at the same time for the same output XBAR_OUT[n].
Chapter 62
Inter-Peripheral Crossbar Switch B (XBARB)

62.1 Chip-specific XBAR information

On this device, for XBAR1 (see the XBARA chapter), the number of inputs is 88, and the number of outputs is 132. For XBAR2 and XBAR3 (see the XBARB chapter), the number of inputs is 64, and the number of outputs is 16.

NOTE
The XBAR_INn and XBAR_OUTn signals (n=4 to 19) share the same IOs. The user needs to configure the corresponding IOMUXC_GPR_GPR6[IOMUXC_XBAR_DIR_SEL_n] bit to use either XBAR_IN or XBAR_OUT.

62.2 Introduction

For a description of the general features and functionality of this module, refer to the XBARA description.
62.3 Memory Map and Register Descriptions

This section provides information about the XBARB instance of the inter-peripheral crossbar switch. Refer to the XBARA register details for information about that instance of the module.

This XBAR module has only select registers.

In the XBAR select registers, the SELn fields select which of the shared inputs (XBAR_IN[*]) is muxed to each mux output (XBAR_OUT[*]). There is one SELn field per mux and therefore one per XBAR_OUT output. Crossbar output XBAR_OUT[n] presents the value of XBAR_IN[SELn]. Each select register contains two SELn fields. In the first select register, the LSBs contain the select field for mux 0, and the MSBs contain the select field for mux 1. The pattern repeats in subsequent select registers.

The actual signals connected to XBAR_IN and XBAR_OUT are application specific and are described in the Chip Configuration details.

63.2 Introduction

The AND/OR/INVERT module (known simply as the AOI module) supports the generation of a configurable number of EVENT signals. Each output EVENT\(n\) is a configurable and/or/invert function of four associated AOI inputs: An, Bn, Cn, and Dn.

This module is designed to be integrated in conjunction with one or more inter-peripheral crossbar switch (XBAR) modules. A crossbar switch is typically used to select the 4*n AOI inputs from among available peripheral outputs and GPIO signals. The n EVENTn outputs from the AOI module are typically used as additional inputs to a second crossbar switch, adding to it the ability to connect to its outputs an arbitrary 4-input boolean function of its other inputs.
The AOI controller is a slave peripheral module connecting event input indicators from a variety of device modules and generating event output signals that can be routed to an inter-peripheral crossbar switch or other peripherals. Its programming model is accessed through the standard IPS (Sky Blue) slave interface. The module is designed to be very configurable in terms of the functionality of its integrated AOI functions.

### 63.2.1 Overview

The AOI module supports a configurable number of event outputs, where each event output represents a user-programmed combinational boolean function based on four event inputs. The key features of this module include:

- Four dedicated inputs for each event output
- User-programmable combinational boolean function evaluation for each event output
- Memory-mapped device connected to a slave peripheral (IPS) bus
- Configurable number of event outputs

**NOTE**

The connections from the AOI module outputs to other functions is SoC-specific.
Figure 63-1. Simplified AOI Block Diagram
63.2.2 Features

The major features of the AOI module are summarized below:

- Highly programmable module for creating combinational boolean events for use as hardware triggers
  - Each channel has four event inputs and one output
  - Evaluates a combinational boolean expression as the sum of four products where each product term includes all four selected input sources available as true or complement values
  - Event output is formed as purely combinational logic and operates as a hardware trigger
- Memory-mapped device connected to the slave peripheral (IPS) bus
  - Programming model organized per channel for simplified software

63.2.3 Modes of Operation

The AOI module does not support any special modes of operation. As shown in Figure 63-1, its operation is primarily controlled by the selected event inputs and outputs. Additionally, as a memory-mapped device located on the slave peripheral bus, it responds based strictly on memory address for accesses to its programming model.

The AOI module resides in the slave peripheral bus clock domain.

63.3 External Signal Description

The AOI module does not directly support any external interfaces. There may be package input signals (indirectly) connected to the module as event inputs, but since the AOI does not include any input synchronization hardware, this function must be handled before the event input signals are routed into the module.

63.4 Memory Map and Register Descriptions

The AOI module supports access to its programming model via a 16-bit peripheral bus connection. The module is designed to support 16-bit accesses only. Functionality for accesses of other widths is undefined.
The AOI module supports a specific number of event outputs. Each output EVENTn outputs a four-term AOI function of four binary inputs: An, Bn, Cn, and Dn. A pair of 16-bit registers configures this four-term AOI function: The two registers BFCRT01n and BFCRT23n define the configuration for the evaluation of the Boolean function defining EVENTn, where \( n \) is the event output channel number. The BFCRT01n register defines the configuration of product terms 0 and 1, and the BFCRT23n register defines the configuration of product terms 2 and 3.

The AOI module provides a universal Boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (An, Bn, Cn, Dn). Specifically, the EVENTn output is defined by the following "4 x 4" Boolean expression:

\[
\text{EVENT}_n = (0, \text{An}, \neg \text{An}, 1) \& (0, \text{Bn}, \neg \text{Bn}, 1) \& (0, \text{Cn}, \neg \text{Cn}, 1) \& (0, \text{Dn}, \neg \text{Dn}, 1) \quad \text{product term 0} \\
(0, \text{An}, \neg \text{An}, 1) \& (0, \text{Bn}, \neg \text{Bn}, 1) \& (0, \text{Cn}, \neg \text{Cn}, 1) \& (0, \text{Dn}, \neg \text{Dn}, 1) \quad \text{product term 1} \\
(0, \text{An}, \neg \text{An}, 1) \& (0, \text{Bn}, \neg \text{Bn}, 1) \& (0, \text{Cn}, \neg \text{Cn}, 1) \& (0, \text{Dn}, \neg \text{Dn}, 1) \quad \text{product term 2} \\
(0, \text{An}, \neg \text{An}, 1) \& (0, \text{Bn}, \neg \text{Bn}, 1) \& (0, \text{Cn}, \neg \text{Cn}, 1) \& (0, \text{Dn}, \neg \text{Dn}, 1) \quad \text{product term 3}
\]

where each selected input of each product term can be configured to produce a logical 0 or 1 or pass the true or complement of the selected event input. Each product term uses 8 bits of configuration information, 2 bits for each of the four selected event inputs. The resulting logic provides a simple yet powerful Boolean function evaluation for defining an event output.

These AOI functions are combinational in nature and are intended to be sampled and used synchronously.

### 63.5 Functional Description

The AOI is a highly programmable module for creating combinational boolean outputs for use as hardware triggers. Each AOI output channel, as shown in Figure 63-1, has one logic function:

- Evaluation of a combinational boolean expression as a sum of four products where each product term includes all four selected input sources available as true or complement values

A typical application of the AOI module is to be integrated with one or more inter-peripheral crossbar switch modules as illustrated in the following figure. The 20 external inputs are shared by two crossbar switch modules. The crossbar switch on the top is used to select the inputs to four 4-input AOI functions in the AOI module. The outputs of these four AOI functions are output from the AOI module and are added to the original 20 external inputs to provide a total of 24 inputs to the bottom crossbar switch. As a result,
the bottom crossbar can not only direct any of the original 20 external inputs to any of its outputs, it can also now direct any one of four 4-input AOI functions of those external inputs to any of its outputs.

Figure 63-2. Integration Example of AOI with two Inter-Peripheral Crossbar Switches

63.5.1 Configuration Examples for the Boolean Function Evaluation

This section presents examples of the programming model configuration for simple boolean expressions.
The AOI module provides a universal boolean function generator using a four-term sum of products expression with each product term containing true or complement values of the four selected event inputs (A, B, C, D). Specifically, the event output is defined by the following “4 x 4” boolean expression:

\[
\text{EVENT} = (0,\text{An},-\text{An},1) \land (0,\text{Bn},-\text{Bn},1) \land (0,\text{Cn},-\text{Cn},1) \land (0,\text{Dn},-\text{Dn},1) // \text{product term 0}
\]
\[
| (0,\text{An},-\text{An},1) \land (0,\text{Bn},-\text{Bn},1) \land (0,\text{Cn},-\text{Cn},1) \land (0,\text{Dn},-\text{Dn},1) // \text{product term 1}
\]
\[
| (0,\text{An},-\text{An},1) \land (0,\text{Bn},-\text{Bn},1) \land (0,\text{Cn},-\text{Cn},1) \land (0,\text{Dn},-\text{Dn},1) // \text{product term 2}
\]
\[
| (0,\text{An},-\text{An},1) \land (0,\text{Bn},-\text{Bn},1) \land (0,\text{Cn},-\text{Cn},1) \land (0,\text{Dn},-\text{Dn},1) // \text{product term 3}
\]

where each selected input term in each product term can be configured to produce a logical 0 or 1 or pass the true or complement of the selected event input. Each product term uses eight bits of configuration information, two bits for each of the four selected event inputs. The actual boolean expression implemented in each channel is:

\[
\text{EVENT} = (\text{PT0 AC}[0] \land A | \text{PT0 AC}[1] \land -A) // \text{product term 0}
\]
\[
& (\text{PT0 BC}[0] \land B | \text{PT0 BC}[1] \land -B)
\]
\[
& (\text{PT0 CC}[0] \land C | \text{PT0 CC}[1] \land -C)
\]
\[
& (\text{PT0 DC}[0] \land D | \text{PT0 DC}[1] \land -D)
\]
\[
| (\text{PT1 AC}[0] \land A | \text{PT1 AC}[1] \land -A) // \text{product term 1}
\]
\[
& (\text{PT1 BC}[0] \land B | \text{PT1 BC}[1] \land -B)
\]
\[
& (\text{PT1 CC}[0] \land C | \text{PT1 CC}[1] \land -C)
\]
\[
& (\text{PT1 DC}[0] \land D | \text{PT1 DC}[1] \land -D)
\]
\[
| (\text{PT2 AC}[0] \land A | \text{PT2 AC}[1] \land -A) // \text{product term 2}
\]
\[
& (\text{PT2 BC}[0] \land B | \text{PT2 BC}[1] \land -B)
\]
\[
& (\text{PT2 CC}[0] \land C | \text{PT2 CC}[1] \land -C)
\]
\[
& (\text{PT2 DC}[0] \land D | \text{PT2 DC}[1] \land -D)
\]
\[
| (\text{PT3 AC}[0] \land A | \text{PT3 AC}[1] \land -A) // \text{product term 3}
\]
\[
& (\text{PT3 BC}[0] \land B | \text{PT3 BC}[1] \land -B)
\]
\[
& (\text{PT3 CC}[0] \land C | \text{PT3 CC}[1] \land -C)
\]
\[
& (\text{PT3 DC}[0] \land D | \text{PT3 DC}[1] \land -D)
\]

where the bits of the combined {BFECRT01n,BFCRT23n} registers correspond to the \( \text{PT}_{0-3}\) \(_{A,B,C,D}C[1:0]\) terms in the equation.

Consider the settings of the combined 32-bit {BFECRT01n,BFCRT23n} registers for several simple boolean expressions as shown in Table 63-2.

Table 63-2. IEVENT_BFECRn Values for Simple Boolean Expressions
As can be seen in these examples, the resulting logic provides a simple yet powerful boolean function evaluation for defining an event output.

63.5.2 AOI Timing Between Inputs and Outputs

Each EVENTn output of the AOI module is a combination function of its four dedicated inputs An, Bn, Cn, and Dn. Propagation through the AOI and any associated inter-peripheral crossbar switch modules is intended to be single bus clock cycle.
Chapter 64
Analog Overview

64.1 Overview

The following analog modules are integrated in this chip:

- Analog-Digital-Converter (ADC) - Supports up to 1MS/s sampling rate and up to 16 single-ended external analog inputs
- Touch Screen Controller (TSC) - Responsible for providing control of the ADC and the touch screen analog block to form a touch screen system
- ADC External Trigger Control (ADC_ETC) - Enables multiple users to share a ADC module in a Time-Division-Multiplexing (TDM) method
- Analog Comparator (ACMP) - Operational over the entire supply range and features a integrated 6-bit DAC and a integrated 8 to 1 channel mux

Below is the simplified block diagram:

![Block Diagram](image-url)

Figure 64-1. Block Diagram (Simplified)
64.1.1 Analog-to-Digital Converter (ADC)

The ADC module features a linear successive approximation algorithm with up to 12-bit resolution with 10/11 bit accuracy. It has three possible states:

- Disabled State - The ADC module is disabled
- Idle state - The ADC module is idle, waiting on a conversion to be initiated
- Conversion State - In this mode, the ADC module can perform analog-to-digital conversion on any of the software selectable channels, using the successive approximation algorithm

64.1.2 Touch Screen Control (TSC)

The TSC helps achieve the function of touch detection and touch location detection. The controller utilizes the ADC hardware trigger function and control switches in the touch screen analog block to form a touch screen system. The controller only supports 4-wire or 5-wire screen touch modes.

64.1.3 ADC External Trigger Control (ADC_ETC)

The ADC_ETC module enables multiple users to share a ADC module. It manages the external trigger mode (HWT) of the ADCs and supports up to x8 HWT for each ADC. It is capable of triggering dual ADCs in SyncMode (controlled by the same trigger source) or AsyncMode (controlled by separate trigger source). Every ADC HWT is configured with a Back-to-Back (B2B) and Interrupt Enable (IE) settings and each external trigger can be configured with a fixed priority.

64.1.4 Analog Comparator (ACMP)

The comparator (CMP) allows for comparing two analog input voltages while the Analog MUX allows for selecting an analog input signal from eight channels. The mux circuit is operational across the full range of the supply voltage. The integrated 6-bit DAC provides a selectable voltage reference for applications where voltage reference is needed.

The ACMPs share the same 3.3V reference voltage with the ADCs.

NOTE

$V_{in1}$ and $V_{in2}$ are all connected to $V_{DDA}$, on this device.

65.2 Introduction

The comparator (CMP) module provides a circuit for comparing two analog input voltages. The comparator circuit is designed to operate across the full range of the supply voltage, known as rail-to-rail operation.

The Analog MUX (ANMUX) provides a circuit for selecting an analog input signal from eight channels. One signal is provided by the 6-bit digital-to-analog converter (DAC). The mux circuit is designed to operate across the full range of the supply voltage.

The 6-bit DAC is 64-tap resistor ladder network which provides a selectable voltage reference for applications where voltage reference is needed. The 64-tap resistor ladder network divides the supply reference $V_{in}$ into 64 voltage levels. A 6-bit digital signal
input selects the output voltage level, which varies from $V_{\text{in}}$ to $V_{\text{in}}/64$. $V_{\text{in}}$ can be selected from two voltage sources, $V_{\text{in}1}$ and $V_{\text{in}2}$. The 6-bit DAC from a comparator is available as an on-chip internal signal only and is not available externally to a pin.

### 65.2.1 CMP features

The CMP has the following features:

- Operational over the entire supply range
- Inputs may range from rail to rail
- Programmable hysteresis control
- Selectable interrupt on rising-edge, falling-edge, or both rising or falling edges of the comparator output
- Selectable inversion on comparator output
- Capability to produce a wide range of outputs such as:
  - Sampled
  - Windowed, which is ideal for certain PWM zero-crossing-detection applications
  - Digitally filtered:
    - Filter can be bypassed
    - Can be clocked via external SAMPLE signal or scaled bus clock
- External hysteresis can be used at the same time that the output filter is used for internal functions
- Two software selectable performance levels:
  - Shorter propagation delay at the expense of higher power
  - Low power, with longer propagation delay
- DMA transfer support
  - A comparison event can be selected to trigger a DMA transfer
  - Functional in all modes of operation
- The window and filter functions are not available in the following modes:
  - Stop
  - VLPS
65.2.2 6-bit DAC key features

The 6-bit DAC has the following features:
- 6-bit resolution
- Selectable supply reference source
- Power Down mode to conserve power when not in use
- Option to route the output to internal comparator input

65.2.3 ANMUX key features

The ANMUX has the following features:
- Two 8-to-1 channel mux
- Operational over the entire supply range

65.2.4 CMP, DAC and ANMUX diagram

The following figure shows the block diagram for the High-Speed Comparator, DAC, and ANMUX modules.
65.2.5  CMP block diagram

The following figure shows the block diagram for the CMP module.

Figure 65-1. CMP, DAC and ANMUX block diagram
In the CMP block diagram:

- The Window Control block is bypassed when CR1[WE] = 0
- If CR1[WE] = 1, the comparator output will be sampled on every bus clock when WINDOW=1 to generate COUTA. Sampling does NOT occur when WINDOW = 0.
- The Filter block is bypassed when not in use.
- The Filter block acts as a simple sampler if the filter is bypassed and CR0[FILTER_CNT] is set to 0x01.
- The Filter block filters based on multiple samples when the filter is bypassed and CR0[FILTER_CNT] is set greater than 0x01.
  - If CR1[SE] = 1, the external SAMPLE input is used as sampling clock
  - If CR1[SE] = 0, the divided bus clock is used as sampling clock
• If enabled, the Filter block will incur up to one bus clock additional latency penalty on COUT due to the fact that COUT, which is crossing clock domain boundaries, must be resynchronized to the bus clock.

• CR1[WE] and CR1[SE] are mutually exclusive.

#### FILTER_CNT

Filter Sample Count

- Represents the number of consecutive samples that must agree prior to the comparator output filter accepting a new output state. For information regarding filter programming and latency, see the Functional description.

- **000** Filter is disabled. If SE = 1, then COUT is a logic 0. This is not a legal state, and is not recommended. If SE = 0, COUT = COUTA.
- **001** One sample must agree. The comparator output is simply sampled.
- **010** 2 consecutive samples must agree.
- **011** 3 consecutive samples must agree.
- **100** 4 consecutive samples must agree.
- **101** 5 consecutive samples must agree.
- **110** 6 consecutive samples must agree.
- **111** 7 consecutive samples must agree.

#### HYSTCTR

Comparator hard block hysteresis control

- Defines the programmable hysteresis level. The hysteresis values associated with each level are device-specific. See the Data Sheet of the device for the exact values.

- **00** Level 0
- **01** Level 1
- **10** Level 2
- **11** Level 3

### 65.4 Functional description

The CMP module can be used to compare two analog input voltages applied to INP and INM.

CMPO is high when the non-inverting input is greater than the inverting input, and is low when the non-inverting input is less than the inverting input. This signal can be selectively inverted by setting CR1[INV] = 1.

SCR[IER] and SCR[IEF] are used to select the condition which will cause the CMP module to assert an interrupt to the processor. SCR[CFF] is set on a falling-edge and SCR[CFR] is set on rising-edge of the comparator output. The optionally filtered CMPO can be read directly through SCR[COUT].
65.4.1 CMP functional modes

There are the following main sub-blocks to the CMP module:

- The comparator itself
- The window function
- The filter function

The filter, CR0[FILTER_CNT], can be clocked from an internal or external clock source. The filter is programmable with respect to the number of samples that must agree before a change in the output is registered. In the simplest case, only one sample must agree. In this case, the filter acts as a simple sampler.

The external sample input is enabled using CR1[SE]. When set, the output of the comparator is sampled only on rising edges of the sample input.

The "windowing mode" is enabled by setting CR1[WE]. When set, the comparator output is sampled only when WINDOW=1. This feature can be used to ignore the comparator output during time periods in which the input voltages are not valid. This is especially useful when implementing zero-crossing-detection for certain PWM applications.

The comparator filter and sampling features can be combined as shown in the following table. Individual modes are discussed below.

<td>0x01–0xFF</td>
<td>Windowed/Filtered mode</td>
</tr>
</tbody>
</table>

Comparator output is sampled on every rising bus clock edge when SAMPLE=1 to generate COUTA, which is then resampled and filtered to generate COUT.

See the Windowed/Filtered mode (#7).

All other combinations of CR1[EN], CR1[WE], CR1[SE], CR0[FILTER_CNT], and FPR[FILT_PER] are illegal.

For cases where a comparator is used to drive a fault input, for example, inverter-control module such as PWM, it must be configured to operate in Continuous mode so that an external fault can immediately pass through the comparator to the target fault circuitry.

**Note**

Filtering and sampling settings must be changed only after setting CR1[SE]=0 and CR0[FILTER_CNT]=0x00. This resets the filter to a known state.

65.4.1.1 Disabled mode (# 1)

In Disabled mode, the analog comparator is non-functional and consumes no power. CMPO is 0 in this mode.

65.4.1.2 Continuous mode (#s 2A & 2B)
Figure 65-3. Comparator operation in Continuous mode

The analog comparator block is powered and active. CMPO may be optionally inverted, but is not subject to external sampling or filtering. Both window control and filter blocks are completely bypassed. SCR[COUT] is updated continuously. The path from comparator input pins to output pin is operating in combinational unclocked mode. COUT and COUTA are identical.

For control configurations which result in disabling the filter block, see the Filter Block Bypass Logic diagram.

65.4.1.3 Sampled, Non-Filtered mode (#s 3A & 3B)
In Sampled, Non-Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising-edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Non-Filtered (# 3B) is in how the clock to the filter block is derived. In #3A, the clock to filter block is externally derived while in #3B, the clock to filter block is internally derived.

The comparator filter has no other function than sample/hold of the comparator output in this mode (# 3B).
Figure 65-5. Sampled, Non-Filtered (# 3B): sampling interval internally derived

### 65.4.1.4 Sampled, Filtered mode (#s 4A & 4B)

In Sampled, Filtered mode, the analog comparator block is powered and active. The path from analog inputs to COUTA is combinational unclocked. Windowing control is completely bypassed. COUTA is sampled whenever a rising edge is detected on the filter block clock input.

The only difference in operation between Sampled, Non-Filtered (# 3A) and Sampled, Filtered (# 4A) is that, now, CR0[FILTER_CNT]>1, which activates filter operation.
Figure 65-6. Sampled, Filtered (# 4A): sampling point externally driven
The only difference in operation between Sampled, Non-Filtered (# 3B) and Sampled, Filtered (# 4B) is that now, CR0[FILTER_CNT]>1, which activates filter operation.

**65.4.1.5 Windowed mode (#s 5A & 5B)**

The following figure illustrates comparator operation in the Windowed mode, ignoring latency of the analog comparator, polarity select, and window control block. It also assumes that the polarity select is set to non-inverting state.

**NOTE**

The analog comparator output is passed to COUTA only when the WINDOW signal is high.

In actual operation, COUTA may lag the analog inputs by up to one bus clock cycle plus the combinational path delay through the comparator and polarity select logic.
For control configurations which result in disabling the filter block, see Filter Block Bypass Logic diagram.
When any windowed mode is active, COUTA is clocked by the bus clock whenever \( \text{WINDOW} = 1 \). The last latched value is held when \( \text{WINDOW} = 0 \).

### 65.4.1.6 Windowed/Resampled mode (# 6)

The following figure uses the same input stimulus shown in Figure 65-8, and adds resampling of COUTA to generate COUT. Samples are taken at the time points indicated by the arrows in the figure. Again, prop delays and latency are ignored for the sake of clarity.

This example was generated solely to demonstrate operation of the comparator in windowed/resampled mode, and does not reflect any specific application. Depending upon the sampling rate and window placement, COUT may not see zero-crossing events detected by the analog comparator. Sampling period and/or window placement must be carefully considered for a given application.

![Figure 65-10. Windowed/resampled mode operation](image-url)

This mode of operation results in an unfiltered string of comparator samples where the interval between the samples is determined by \( \text{FPR[FILT_PER]} \) and the bus clock rate. Configuration for this mode is virtually identical to that for the Windowed/Filtered Mode shown in the next section. The only difference is that the value of \( \text{CR0[FILTER_CNT]} \) must be 1.
65.4.1.7 Windowed/Filtered mode (#7)

This is the most complex mode of operation for the comparator block, as it uses both windowing and filtering features. It also has the highest latency of any of the modes. This can be approximated: up to 1 bus clock synchronization in the window function + ((CR0[FILTER_CNT] * FPR[FILT_PER]) + 1) * bus clock for the filter function.

When any windowed mode is active, COUTA is clocked by the bus clock whenever WINDOW = 1. The last latched value is held when WINDOW = 0.

![Figure 65-11. Windowed/Filtered mode](image)

65.4.2 Power modes

65.4.2.1 Wait mode operation

During Wait and VLPW modes, the CMP, if enabled, continues to operate normally and a CMP interrupt can wake the MCU.
65.4.2.2  Stop mode operation

Depending on clock restrictions related to the MCU core or core peripherals, the MCU is brought out of stop when a compare event occurs and the corresponding interrupt is enabled. Similarly, if CR1[OPE] is enabled, the comparator output operates as in the normal operating mode and comparator output is placed onto the external pin. In Stop modes, the comparator can be operational in both:

- High-Speed (HS) Comparison mode when CR1[PMODE] = 1
- Low-Speed (LS) Comparison mode when CR1[PMODE] = 0

It is recommended to use the LS mode to minimize power consumption.

If stop is exited with a reset, all comparator registers are put into their reset state.

65.4.3  Startup and operation

A typical startup sequence is listed here.

- The time required to stabilize COUT will be the power-on delay of the comparators plus the largest propagation delay from a selected analog source through the analog comparator, windowing function and filter. See the Data Sheets for power-on delays of the comparators. The windowing function has a maximum of one bus clock period delay. The filter delay is specified in the Low-pass filter.
- During operation, the propagation delay of the selected data paths must always be considered. It may take many bus clock cycles for COUT and SCR[CFR]/SCR[CFF] to reflect an input change or a configuration change to one of the components involved in the data path.
- When programmed for filtering modes, COUT will initially be equal to 0, until sufficient clock cycles have elapsed to fill all stages of the filter. This occurs even if COUTA is at a logic 1.

65.4.4  Low-pass filter

The low-pass filter operates on the unfiltered and unsynchronized and optionally inverted comparator output COUTA and generates the filtered and synchronized output COUT.

Both COUTA and COUT can be configured as module outputs and are used for different purposes within the system.
Synchronization and edge detection are always used to determine status register bit values. They also apply to COUT for all sampling and windowed modes. Filtering can be performed using an internal timebase defined by FPR[FILT_PER], or using an external SAMPLE input to determine sample time.

The need for digital filtering and the amount of filtering is dependent on user requirements. Filtering can become more useful in the absence of an external hysteresis circuit. Without external hysteresis, high-frequency oscillations can be generated at COUTA when the selected INM and INP input voltages differ by less than the offset voltage of the differential comparator.

### 65.4.4.1 Enabling filter modes

Filter modes can be enabled by:

- Setting CR0[FILTER_CNT] > 0x01 and
- Setting FPR[FILT_PER] to a nonzero value or setting CR1[SE]=1

If using the divided bus clock to drive the filter, it will take samples of COUTA every FPR[FILT_PER] bus clock cycles.

The filter output will be at logic 0 when first initialized, and will subsequently change when all the consecutive CR0[FILTER_CNT] samples agree that the output value has changed. In other words, SCR[COUT] will be 0 for some initial period, even when COUTA is at logic 1.

Setting both CR1[SE] and FPR[FILT_PER] to 0 disables the filter and eliminates switching current associated with the filtering process.

**Note**

Always switch to this setting prior to making any changes in filter parameters. This resets the filter to a known state. Switching CR0[FILTER_CNT] on the fly without this intermediate step can result in unexpected behavior.

If CR1[SE]=1, the filter takes samples of COUTA on each positive transition of the sample input. The output state of the filter changes when all the consecutive CR0[FILTER_CNT] samples agree that the output value has changed.
65.4.4.2 Latency issues

The value of FPR[FILT_PER] or SAMPLE period must be set such that the sampling period is just longer than the period of the expected noise. This way a noise spike will corrupt only one sample. The value of CR0[FILTER_CNT] must be chosen to reduce the probability of noisy samples causing an incorrect transition to be recognized. The probability of an incorrect transition is defined as the probability of an incorrect sample raised to the power of CR0[FILTER_CNT].

The values of FPR[FILT_PER] or SAMPLE period and CR0[FILTER_CNT] must also be traded off against the desire for minimal latency in recognizing actual comparator output transitions. The probability of detecting an actual output change within the nominal latency is the probability of a correct sample raised to the power of CR0[FILTER_CNT].

The following table summarizes maximum latency values for the various modes of operation in the absence of noise. Filtering latency is restarted each time an actual output transition is masked by noise.

</tbody>
</table>

1. T<sub>PD</sub> represents the intrinsic delay of the analog component plus the polarity select logic. T<sub>SAMPLE</sub> is the clock period of the external sample clock. T<sub>per</sub> is the period of the bus clock.
65.5 CMP interrupts

The CMP module is capable of generating an interrupt on either the rising- or falling-edge of the comparator output, or both.

The following table gives the conditions in which the interrupt request is asserted and deasserted.

<table>
<thead>
<tr>
<th>When</th>
<th>Then</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCR[IER] and SCR[CFR] are set</td>
<td>The interrupt request is asserted</td>

<td>The interrupt request is deasserted</td>
</tr>
<tr>
<td>SCR[IEF] and SCR[CFF] are cleared for a falling-edge interrupt</td>
<td>The interrupt request is deasserted</td>
</tr>
</tbody>
</table>

65.6 DMA support

Normally, the CMP generates a CPU interrupt if there is a change on the COUT. When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request rather than a CPU interrupt instead. When the DMA has completed the transfer, it sends a transfer completing indicator that deasserts the DMA transfer request and clears the flag to allow a subsequent change on comparator output to occur and force another DMA request.

The comparator can remain functional in STOP modes.

When DMA support is enabled by setting SCR[DMAEN] and the interrupt is enabled by setting SCR[IER], SCR[IEF], or both, the corresponding change on COUT forces a DMA transfer request to wake up the system from STOP modes. After the data transfer has finished, system will go back to STOP modes. Refer to DMA chapters in the device reference manual for the asynchronous DMA function for details.
65.7 Digital-to-analog converter

The figure found here shows the block diagram of the DAC module.

It contains a 64-tap resistor ladder network and a 64-to-1 multiplexer, which selects an output voltage from one of 64 distinct levels that outputs from DACO. It is controlled through the DAC Control Register (DACCR). Its supply reference source can be selected from two sources $V_{in1}$ and $V_{in2}$. The module can be powered down or disabled when not in use. When in Disabled mode, DACO is connected to the analog ground.

![Figure 65-12. 6-bit DAC block diagram](image)

65.8 DAC functional description

This section provides DAC functional description information.

65.8.1 Voltage reference source select

- $V_{in1}$ connects to the primary voltage source as supply reference of 64 tap resistor ladder
- $V_{in2}$ connects to an alternate voltage source
65.9 DAC resets
This module has a single reset input, corresponding to the chip-wide peripheral reset.

65.10 DAC clocks
This module has a single clock input, the bus clock.

65.11 DAC interrupts
This module has no interrupts.

66.2 Overview

The analog-to-digital converter (ADC) is a successive approximation ADC designed for operation within an integrated microcontroller system-on-chip.

66.2.1 Features

The features of the ADC are as follows:

- Configuration registers
• 32-bit, word aligned, byte enabled registers. (byte and halfword access is not supported)
• Linear successive approximation algorithm with up to 12-bit resolution with 10/11 bit accuracy.
• Up to 10 ENOB (dedicated single ended channels)
• Up to 1MS/s sampling rate
• Up to 16 single-ended external analog inputs
• Single or continuous conversion (automatic return to idle after single conversion)
• Output Modes: (in right-justified unsigned format)
  • 12-bit
  • 10-bit
  • 8-bit
• Configurable sample time and conversion speed/power
• Conversion complete and hardware average complete flag and interrupt
• Input clock selectable from up to three sources
• Asynchronous clock source for lower noise operation with option to output the clock
• Selectable asynchronous hardware conversion trigger with hardware channel select
• Automatic compare with interrupt for less-than, greater-than or equal-to, within range, or out-of-range, programmable value
• Operation in low power modes for lower noise operation
• Hardware average function
• Self-calibration mode

66.2.2 ADC I/F block diagram

The following diagram represents the ADC I/F block.
66.2.3 ADC block diagram

The following figure shows a top-level block diagram of the ADC module.
66.2.4 ADC module interface

The ADC is connected to many interfaces such as the clocks and reset, access bus, voltage references, interrupt controller, hardware triggers, ADC pin control, and analog I/F as shown in the following figure.
66.2.5 Modes of Operation

By default, the ADC is in disabled mode. In this state, no conversion or other actions occur. All of the ADC control registers are accessible in this state through an access bus interface. To enable the ADC, required configurations should be done by programming the ADC configuration registers.

66.3 External Signals

The following table describes the external signals of ADC:

### 66.5 Functional Description

There are three possible states which ADC module can be in:

1. Disabled State
2. Idle state
3. Performing conversions

**Disabled State:**

The ADC module is disabled during reset or stop mode (if internal clock is not selected as source of clock), or when the ADCH bits of the hardware control (ADC_HCn) registers are all high.

**Idle State:**
The module is idle when a conversion has completed and another conversion has not been initiated. When idle and the asynchronous clock output enable is disabled (ADACKEN = 0), the module is in its lowest power state.

**Conversion State:**

The ADC can perform an analog-to-digital conversion on any of the software selectable channels. All modes perform conversion by a successive approximation algorithm.

To meet accuracy specifications the ADC module must be calibrated using the on chip calibration function. Calibration is recommended to be done after any reset.

When the conversion is completed, the result is placed in the data result registers (ADC_Rn). The conversion complete flag (COCOn) field in the Hardware Status register is/are then set and an interrupt is generated, if the respective conversion complete interrupt has been enabled (ADC_HCn[AIEN]=1).

The ADC module has the capability of automatically comparing the result of a conversion with the contents of the compare value registers. The compare function is enabled by setting ACFE (ADC Compare Function Enable) in the ADC general control register.

The ADC module has the capability of automatically averaging the result of multiple conversions. The hardware average function is enabled by setting AVGE in the ADC general control register.

### 66.5.1 Clock Select and Divide Control

The ADC digital module has two clock sources:

- IPG clock
- Internal clock (ADACK) is a dedicated clock used only by the ADC.

ADC digital block generates IPG clock/2 by internally dividing the IPG clock. The final clock is chosen from the following clocks.

- IPG clock
- IPG clock divided by 2
- ADACK

From the three clocks listed above, one is chosen depending on the configuration of ADICLK[1:0] bits of ADC_CFG. This chosen clock is divided depending on the configuration of ADIV[1:0] bits of ADC_CFG. The final generated clock is used as conversion clock for ADC.
<table>
<thead>
<tr>
<th>ADICLK</th>
<th>Selected Clock Source</th>
</tr>
</thead>
<tbody>
<tr>
<td>00</td>
<td>IPG clock</td>
</tr>
<tr>
<td>01</td>
<td>IPG clock divided by 2</td>
</tr>
<tr>
<td>10</td>
<td>Reserved</td>
</tr>
<tr>
<td>11</td>
<td>Asynchronous clock (ADACK)</td>
</tr>
</tbody>
</table>

- The IPG clock. This is the default selection following reset.
- The IPG clock divided by two. For higher IPG clock rates, this allows a maximum divide by 16 of the IPG clock using the ADIV bits.
- The asynchronous clock (ADACK). This clock is generated from a clock source within the ADC module. Conversions are possible using ADACK as the input clock source while the MCU is in stop mode.

Whichever clock is selected, its frequency must fall within the specified frequency range for ADCK. If the available clocks are too slow, the ADC may not perform according to specifications. If the available clocks are too fast, the clock must be divided to the appropriate frequency. This divider is specified by the ADIV bits and can be divide-by 1, 2, 4, or 8.

### 66.5.2 Voltage Reference Selection

The ADC can be configured to use reference pairs as the reference voltages used for conversions ($V_{REFSH}$ and $V_{REFSL}$). Each pair contains a positive reference which must be between the minimum Ref Voltage High and $V_{DDAD}$, and a ground reference which must be at the same potential as $V_{SSAD}$. The pairs can be as follows:

- External ($V_{REFH}$ and $V_{REFL}$)

These voltage references are selected by configuring ADC_CFG[REFSEL].

### 66.5.3 Hardware Triggering and Channel Selection

The ADC module has a trigger input (known as Alternate Trigger) which provides asynchronous hardware conversion trigger when the ADTRG bit in ADC configuration register (ADC_CFG) is set and any of the external hardware trigger select is high.

To be reliably captured, the Alternate Trigger pulse must be high for sufficient time to satisfy clocking requirement of capturing Flop and the external hardware trigger select event must be set for sufficient time before and after the positive edge of Alternate trigger pulse to meet the setup / hold requirement of capturing flop.
If an external hardware trigger select event gets asserted during a conversion it must stay asserted until end of current conversion and remain set until the receipt of the Alternate Trigger to initiate a new conversion.

When the Alternate Trigger source is available and hardware triggering is enabled (ADC_CFG[ADTRG]=1), a conversion is initiated on the rising edge of the Alternate Trigger after a external hardware trigger select event has occurred.

If a conversion is in progress when a rising edge of a trigger occurs, the rising edge is ignored. In continuous conversion configuration, only the initial rising edge to launch continuous conversions is observed and until conversion gets aborted the ADC will continue to do conversions on the same ADC Hardware Trigger Control register that initiated the conversion. The hardware trigger function operates in conjunction with any of the conversion modes and configurations.

The channel selected for the conversion will depend on the settings of active Hardware Trigger register field ADC_HCn[ADCH] of enabled external hardware trigger.

**NOTE**

Asserting more than one external hardware trigger select signal at the same time will result in unknown results. To avoid this, only select one external hardware trigger select signal prior to the next intended conversion.

When the conversion is completed, the result is placed in the data registers associated with the external hardware trigger received (active trigger selects ADC_Rn). The conversion complete flag associated with the external hardware trigger received (ADC_HS[COCOn]) is then set and an interrupt is generated if the respective conversion complete interrupt has been enabled (ADC_HCn[AIEN]=1).

### 66.5.4 Conversion Control

Conversions are performed as determined by ADC_CFG[MODE] field.

Conversions can be initiated by either software or hardware triggers. In addition, the ADC can be configured for low power operation, long sample time, continuous conversion, hardware average, and automatic comparison of conversion results with predetermined values.

### 66.5.4.1 Initiating Conversions

A conversion is initiated:
Following a write to ADC_HC0 (with ADCHn bits not all 1's) and when a software triggered operation is selected (ADTRG=0).

Following a hardware trigger event if hardware triggered operation is selected (ADTRG=1) and a external hardware trigger select event has occurred. The channel selected will depend on the active trigger select signal active selects ADC_HC1; if neither is active the off condition is selected).

**Note**

Selecting more than one external hardware trigger select signal (ext_hwts[n]) prior to a conversion completion will generate unknown results. To avoid this, only select one hardware trigger select signal (ext_hwts[n]) prior to a conversion completion.

Following the transfer of the result to the data registers when continuous conversion is enabled (ADCO=1 in ADC_GC register).

If continuous conversion is enabled, a new conversion is automatically initiated after the completion of the current conversion. In software triggered operation (ADTRG=0), continuous conversions begin after ADC_HC0 is written and continue until aborted. In hardware triggered operation (ADTRG=1 and one external hardware trigger select event has occurred), continuous conversions begin after a hardware trigger event and continue until aborted.

If hardware averaging is enabled, a new conversion is automatically initiated after the completion of the current conversion until the correct number of conversions is completed. In software triggered operation, conversions begin after ADC_HC0 is written. In a hardware triggered operation, conversions begin after a hardware trigger. If continuous conversions is also enabled, a new set of conversions to be averaged are initiated following the last of the selected number of conversions.

### 66.5.4.2 Completing Conversions

A conversion is completed when the result of the conversion is transferred into the data result registers. (provided the compare function & hardware averaging is disabled), this is indicated by the setting of COCOn. If hardware averaging is enabled, COCOn sets only, if the last of the selected number of conversions is complete. If the compare function is enabled, COCOn sets and conversion result data is transferred only if the compare condition is true. If both hardware averaging and compare functions are enabled, then COCOn sets only if the last of the selected number of conversions is complete and the
compare condition is true. An interrupt is generated, if ADC_HCn[AIEN] is high at the
time that COCOn is set and if DMAEN is set, DMA request is asserted, if COCOn is set.
Both the requests get deasserted when COCOn is low, cleared, which happens when data
is read.

In all modes a blocking mechanism prevents a new result from overwriting previous data
in ADC_Rn, if the previous data is in the process of being read. When blocking is active
(OVWREN=0 in ADC_CFG), the conversion result data transfer is blocked, COCOn is
not set, and the new result is lost. In all other cases of operation, when a conversion result
data transfer is blocked, another conversion is initiated regardless of the state of ADCO
(single or continuous conversions enabled).

**Note**

If continuous conversions are enabled, the blocking mechanism
could result in the loss of data occurring at specific timepoints.
To avoid this issue, the data must be read in fewer cycles than
an ADC conversion time, accounting for interrupt or software
polling loop latency.

If single conversions are enabled, the blocking mechanism
could result in several discarded conversions and excess power
consumption. To avoid this issue, the data registers must not be
read after initiating a single conversion until the conversion
completes.

### 66.5.4.3 Aborting Conversions

Any conversion in progress is aborted when:

- The MCU enters stop mode with ADACK not enabled.
- In software trigger mode, write to ADC_HC0 register, while ADC_HC0 is actively
  (already) controlling a conversion, aborts the current conversion. Since none of the
  ADC_HC1 - ADC_HCn registers are used for software trigger operation, writing to
  any of them will not initiate a new conversion nor abort the software triggered active
  conversion.
• In hardware trigger mode, writing to any of the ADC_HC0 - ADC_HCn registers, while that specific register is actively controlling a conversion, will abort the current conversion.

• A write to any ADC register other than the ADC_HC0: ADC_HCn registers occurs. This indicates a mode of operation change has occurred and the current conversion is therefore invalid.

Note

When a conversion is aborted, the contents of the data result registers, ADCRn are not altered. The data result registers continue to hold the values, transferred after the completion of the last successful conversion. If the conversion is aborted by a reset or stop (not operated with internal ADACK), ADCRn (data result register) return to their reset states.

66.5.4.4 Power Control

The ADC module remains in its idle state until a conversion is initiated. If ADACK is selected as the conversion clock source but the asynchronous clock output is disabled (ADACKEN=0), the ADACK clock generator will also remain in its idle state (disabled) until a conversion is initiated. If the asynchronous clock output is enabled (ADACKEN=1), it will remain active regardless of the state of the ADC or the MCU power mode.

Power consumption when the ADC is active can be reduced by setting ADLPC.

66.5.4.5 Sample Time and Total Conversion Time

The total conversion time depends upon the following:

• the sample phase time (as determined by ADLSMP and ADSTS bits in ADC_CFG register),
• the compare phase time (determined by MODE bits)
• the frequency of the conversion clock ($f_{ADCK}$),
• the MCU bus frequency (for Handshaking and selection of clock)
After the module becomes active, sampling of the input begins. ADLSMP and ADSTS decide the sample time duration. When sampling is complete, the converter is isolated from the input channel and a successive approximation algorithm is performed to determine the digital value of the analog signal. The result of the conversion is transferred to ADC_Rn upon completion of the conversion algorithm.

If the bus frequency is less than the $f_{ADCK}$ frequency, precise sample time for continuous conversions cannot be guaranteed.

The maximum total conversion time is determined by the clock source chosen and the divide ratio selected. The clock source is selectable by the ADICLK bits in ADC_CFG register, and the divide ratio is specified by the ADIV bits.

The maximum total conversion time for all configurations is summarized in Equation 1 on page 3338. Refer to Table 66-4 through Table 66-7 for the variables referenced in the equation.

$$\text{ConversionTime} = \text{SFCAdder} + \text{AverageNum} \times (\text{BCT} + \text{LSTAdder})$$

**Equation 1. Equation of Conversion Time**

Note

The ADCK frequency must be between $f_{ADCK}$ minimum and $f_{ADCK}$ maximum to meet ADC specifications.
66.5.4.6 Conversion Time Examples

The following examples uses Equation 1 on page 3338 and the information provided in tables Table 66-4 through Table 66-7.

66.5.4.6.1 Typical conversion time configuration

A typical configuration for ADC conversion is: 10-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 40 MHz, ADLSMP=0, ADLSTS=10 and high speed conversion disabled. The conversion time for a single conversion is calculated by using Equation 1 on page 3338 and the information provided in Table 66-8 through Table 66-10. The table below list the variables of Equation 1 on page 3338.

Table 66-8. Typical Conversion Time

<table>
<thead>
<tr>
<th>Variable</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>SFCAdder</td>
<td>4 ADCK cycles + 2 bus clock cycles</td>
</tr>
<tr>
<td>AverageNum</td>
<td>1</td>
</tr>
<tr>
<td>BCT</td>
<td>21 ADCK cycles</td>
</tr>
<tr>
<td>LSTAdder</td>
<td>7</td>
</tr>
</tbody>
</table>

The resulting conversion time is generated using the parameters listed in Table 66-8. So for Bus clock equal to 40 Mhz and ADCK equal to 40 Mhz the resulting conversion time is 0.85 us.

66.5.4.6.2 Long conversion time configuration

A configuration for long ADC conversion is: 12-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-8 ratio selected, and a bus frequency of 40 MHz, long sample time enabled (ADLSMP=1, ADSTS=11) and configured for longest adder and high speed conversion disabled. Average enabled for 32 conversions (AVGE=1, AVGS=11). The conversion time for this conversion is calculated by using equation on Sample Time and Total Conversion Time and the information provided in Table 66-4 through Table 66-7. The table below lists the variables of equation.

Table 66-9. Typical Conversion Time

<table>
<thead>
<tr>
<th>Variable</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>SFCAdder</td>
<td>4 ADCK cycles + 2 bus clock cycles</td>
</tr>
<tr>
<td>AverageNum</td>
<td>32</td>
</tr>
<tr>
<td>BCT</td>
<td>25 ADCK cycles</td>
</tr>
<tr>
<td>LSTAdder</td>
<td>25 ADCK cycles</td>
</tr>
</tbody>
</table>
The resulting conversion time is generated using the parameters listed in Table 66-9. So for Bus clock equal to 40 Mhz and ADCK equal to 5 Mhz the resulting conversion time is 10.0226 us (AverageNum). This results in a total conversion time of 320.85 us.

66.5.4.6.3 Short conversion time configuration

A configuration for short ADC conversion is: 8-bit mode, with the bus clock selected as the input clock source, the input clock divide-by-1 ratio selected, and a bus frequency of 40 MHz, long sample time disabled (ADLSMP=0, ADSTS=00) and high speed conversion enabled. The conversion time for this conversion is calculated by using the equation and the information provided in Table 66-4 to Table 66-7. The table below list the variables of equation.

<table>
<thead>
<tr>
<th>Variable</th>
<th>Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>SFCAdder</td>
<td>4 ADCK cycles + 2 bus clock cycles</td>
</tr>
<tr>
<td>AverageNum</td>
<td>1</td>
</tr>
<tr>
<td>BCT</td>
<td>17 ADCK cycles</td>
</tr>
<tr>
<td>LSTAdder</td>
<td>3 ADCK cycles</td>
</tr>
</tbody>
</table>

The resulting conversion time is generated using the parameters listed in Table 66-10. So for Bus clock equal to 40Mhz and ADCK equal to 40Mhz the resulting conversion time is 650 ns.

66.5.4.7 Hardware Average Function

The hardware average function can be enabled (AVGE=1) to perform a hardware average of multiple conversions. The number of conversions is determined by the AVGS[1:0] bits, which select 4, 8, 16 or 32 conversions to be averaged. While the hardware average function is in progress the ADACT bit will be set.

After the selected input is sampled and converted, the result is placed in an accumulator from which an average is calculated after the selected number of conversions has been completed. When hardware averaging is selected the completion of a single conversion will not set the COCOn bit.

If the compare function is either disabled or evaluates true, after the selected number of conversions are completed, the average conversion result is transferred into the data result registers, ADC_Rn, and the COCOn bit is set. An ADC interrupt is generated upon the setting of COCOn if the respective ADC interrupt is enabled (AIENn=1).
66.5.5 Automatic Compare Function

The compare function can be configured to check if the result is less than or greater-than-or-equal-to a single compare value, or if the result falls within or outside a range determined by two compare values. The compare mode is determined by ACFG, ACREN and the values in the compare value register (ADC.CV). After the input is sampled and converted, the compare values (CV1 and CV2) are used as described in the table below. There are six compare modes as shown in the table below.

<table>
<thead>
<tr>
<th>ACFG</th>
<th>ACREN</th>
<th>CV1 relative to CV2</th>
<th>Function</th>
<th>Compare Mode Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>0</td>
<td>Less than threshold</td>
<td>Less than threshold</td>
<td>Compare true if the result is less than the CV1 registers.</td>
</tr>
<tr>
<td>1</td>
<td>0</td>
<td>Greater than or equal to threshold</td>
<td>Greater than or equal to threshold</td>
<td>Compare true if the result is greater than or equal to CV1 registers.</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Less than or equal</td>
<td>Outside range, not inclusive</td>
<td>Compare true if the result is less than CV1 Or the result is Greater than CV2</td>
</tr>
<tr>
<td>0</td>
<td>1</td>
<td>Greater than</td>
<td>Inside range, not inclusive</td>
<td>Compare true if the result is less than CV1 And the result is greater than CV2</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Less Than or equal</td>
<td>Inside range, inclusive</td>
<td>Compare true if the result is greater than or equal to CV1 And the result is less than or equal to CV2</td>
</tr>
<tr>
<td>1</td>
<td>1</td>
<td>Greater than</td>
<td>Outside range, inclusive</td>
<td>Compare true if the result is greater than or equal to CV1 Or the result is less than or equal to CV2</td>
</tr>
</tbody>
</table>

With the ADC range enable bit set, ADCREN = 1, if compare value 1 (CV1 value) is less than or equal to the compare value 2 (CV2 value), setting ACFG will select a trigger-if-inside-compare-range, inclusive-of-endpoints function. Clearing ACFG will select a trigger-if-outside-compare-range, not-inclusive-of-endpoints function.

If CV1 is greater than the CV2, setting ACFG will select a trigger-if-outside-compare-range, inclusive-of-endpoints function. Clearing ACFG will select a trigger-if-inside-compare-range, not-inclusive-of-endpoints function.

If the condition selected evaluates true, COCON is set.

Upon completion of a conversion while the compare function is enabled, if the compare condition is not true, COCON is not set and the conversion result data will not be transferred to the result register. If the hardware averaging function is enabled, the compare function compares the averaged result to the compare values. The same compare function definitions apply. An ADC interrupt is generated upon the setting of COCON if the respective ADC interrupt is enabled (ADC_HCn[AIEN]=1).
Note

The compare function can monitor the voltage on a channel while the MCU is in wait or stop3 mode. The ADC interrupt wakes the MCU when the compare condition is met.

66.5.6 Calibration Function

The ADC contains a self-calibration function that is required to achieve the specified accuracy. Calibration should be run or valid calibration values should be written after power up and system reset (as the calibration register will be reset on reset assertion) with specified settings before any conversion is initiated. The calibration function sets the calibration value at the end of running the full calibration sequence in ADC_CAL register. The user must configure the ADC correctly prior to starting the calibration process, and must allow the process to run the full calibration sequence by checking the status of ADC_GC[CAL] and ADC_GS[CALF] so that the generated calibration value can be loaded.

Prior to calibration, the user must configure the ADC's clock source and frequency, low power configuration, voltage reference selection, sample time, averaging, and the high speed configuration according to the application's clock source availability and needs. If the application uses the ADC in a wide variety of configurations, the configuration for which the highest accuracy is required should be selected, or multiple calibrations can be done for the different configurations. The input channel, conversion mode, continuous function and compare function are all ignored during the calibration process.

To initiate calibration, the user sets the CAL bit and the calibration will automatically begin if the ADTRG bit = 0. If ADTRG = 1, the CAL bit will not get set and the calibration fail flag (CALF) will be set. While calibration is active, no ADC register can be written and no stop mode may be entered or the calibration routine will be aborted causing the CAL bit to clear and the CALF bit to set.

At the end of a calibration sequence the COCO[0] bit of the ADC_HS register will be set. The ADC_HCn[AIEN] bit can be used to allow an interrupt to occur at the end of a calibration sequence. If, at the end of calibration routine, the CALF bit is not set, the automatic calibration routine completed successfully.

To complete calibration, the user must follow the below procedure:

- Configure ADC_CFG with actual operating values for maximum accuracy.
- Configure the ADC_GC values along with CAL bit
- Check the status of CALF bit in ADC_GS and the CAL bit in ADC_GC
- When CAL bit becomes '0' then check the CALF status and COCO[0] bit status
When complete the user may reconfigure and use the ADC as desired.

A second calibration may also be performed if desired by clearing and again setting the CAL bit

Overall the calibration routine may take as many as 14000 ADCK cycles and 100 bus cycles, depending on the results and the clock source chosen.

### 66.5.7 User Defined Offset Function

The ADC Offset Correction Register (ADC_OFS) contains the user configured offset value. This register is 13 bit wide. The value in MSB (13th bit) is the operation bit, if this bit is ‘0’ then the value in rest 12 bit is added with the converted result value to generate final result to be loaded into ADC_Rn and if this bit is ‘1’ then this field is subtracted from converted value to generate final Result (ADC_Rn). If the Final result is above the maximum or below the minimum result value, it is forced to the appropriate limit for the current mode of operation. Forced to 0x0FFF if over and 0x0000 if lower for 12 bit mode.

The offset value has no effect during calibration on the final result.

The formatting of the ADC Offset Register is different from the Data Result Registers (ADC_Rn) to preserve the resolution of the value regardless of the conversion mode selected. Lower order bits are ignored in lower resolution modes. For example, in 8b single-ended mode, the bits OFS[11:4] are subtracted from D[7:0] when bit OFS[12] (sign bit) is ‘1’; indicates subtraction and bits OFS[4:0] are ignored. For 12b single-ended mode, bits OFS[11:0] are directly subtracted from the conversion result data CDATA[11:0] when OFS[12] (sign bit) is ‘1’. The similar is the addition operation when OFS[12](sign bit) is 0.

ADC_OFS is manually set according to user requirements after the self calibration sequence is done (CAL is cleared). The user have to write ADC_OFS with desired value.

**NOTE**

There is an effective limit to the values of Offset that can be set by the user. If the magnitude of the offset is too great the results of the conversions will cap off at the limits.

The offset function may be employed by the user to remove application offsets or DC bias values. An offset correction that results in an out-of-range value will be forced to the minimum or maximum value.
For applications which may change the offset repeatedly during operation, it is recommended to store the initial offset value in flash so that it can be recovered and added to any user offset adjustment value and the sum stored in the ADC_OFS registers.

66.5.8 MCU Wait Mode Operation

Wait mode is a **lower power-consumption standby mode** from which **recovery is fast** because **the clock sources remain active**. If a conversion is in progress when the MCU enters wait mode, it continues until completion. Conversions can be initiated while the MCU is in wait mode by means of the hardware trigger or if continuous conversions are enabled.

The bus clock, bus clock divided by two, and ADACK are available as conversion clock sources while in wait mode.

A conversion complete event sets the COCON and generates an ADC interrupt to wake the MCU from wait mode.

If the compare and hardware averaging functions are disabled, a conversion complete event sets the COCON and generates an ADC interrupt to wake the MCU from wait mode if the respective ADC interrupt is enabled (ADC_HCn[AIEN]=1).

If the hardware averaging function is enabled the COCON will set (and generate an interrupt if enabled) when the selected number of conversions are complete.

If the compare function is enabled the COCON will set (and generate an interrupt if enabled) only if the compare conditions are met.

If a single conversion is selected and the compare trigger is not met, the ADC will return to its idle state and cannot wake the MCU from wait mode unless a new conversion is initiated by the hardware trigger.

66.5.9 MCU Stop Mode Operation

Stop mode is a low power-consumption standby mode during which most or all clock sources on the MCU are disabled. Stop mode is entered when stop indication comes from the MCU.
66.5.9.1 Stop Mode With ADACK Disabled

If the asynchronous clock, ADACK, is not selected as the conversion clock, executing a stop instruction aborts the current conversion and places the ADC in its idle state. The contents of the ADC registers, including ADC_Rn are unaffected by stop mode. After exiting from stop mode, a software or hardware trigger is required to resume conversions.

66.5.9.2 Stop Mode With ADACK Enabled

If ADACK is selected as the conversion clock, the ADC continues operation during stop mode. For guaranteed ADC operation, the MCU's voltage regulator must remain active during stop mode.

If a conversion is in progress when the MCU enters stop mode, it continues until completion. Conversions can be initiated while the MCU is in stop mode by means of the hardware trigger or if continuous conversions are enabled.

A conversion complete event sets the COCOn and generates an ADC interrupt to wake the MCU from stop mode:

Note

The ADC module can wake the system from low-power stop and cause the MCU to begin consuming run-level currents without generating a system level interrupt. To prevent this scenario, software should ensure the conversion result data transfer blocking mechanism (discussed in Completing Conversions) is cleared when entering stop and continuing ADC conversions.

66.6 Initialization Information

This section gives an example that provides some basic direction on how to initialize and configure the ADC module. User can configure the module for 8, 10, 12 bit resolution, single or continuous conversion, and a polled or interrupt approach, among many other options.

66.6.1 ADC Module Initialization Example

This section describes the initialization sequence along with pseudo-code.
66.6.1.1 Initialization Sequence

Before the ADC module can be used to complete conversions, an initialization procedure must be performed. A typical sequence is as follows:

- Calibrate the ADC by following the calibration instructions in Calibration Function.
- Update the configuration register (ADC_CFG) to select the input clock source and the divide ratio used to generate the internal clock, ADCK. This register is also used for selecting sample time and low-power configuration.
- Update General control register (ADC_GC) to select whether conversions will be continuous or completed only once (ADCO) and to select whether to perform hardware averaging, etc.
- Update Trigger control register (ADC_HCn) to select the conversion trigger (hardware or software, i.e. configure ADTRG bit) and compare function options, if enabled.

66.6.1.2 Pseudo-Code Example

In this example, the ADC module is set up with interrupts enabled to perform a single 10-bit conversion at low power with a long sample time on input channel 1, where the internal ADCK clock is derived from the bus clock divided by 1.

**ADC_CFG**

Bit 7 ADLPC  1  Configures for low power (lowers maximum clock speed).
Bit 6:5 ADIV  00  Sets the ADCK to the input clock ÷ 1.
Bit 4 ADLSMP 1  Configures for long sample time.
Bit 3:2 MODE 10  Sets mode at 10-bit conversions.
Bit 1:0 ADICLK 00  Selects bus clock as input clock source.

**ADC_GC**

Bit 7 CAL 0  Flag indicates if a conversion is in progress.
Bit 6 ADCO 0  Software trigger selected.
Bit 5 AVGE 0  Compare function disabled.
Bit 4 ACFE 0  Compare function disabled.
Bit 3 ACFGT 0  Not used in this example.
Bit 2 ACREN 0  Not used in this example.
Bit 1 DMAEN 0  Not used in this example.
Bit 0 ADACKEN 0  Not used in this example.

**ADC_HC0**
Bit 7  AIEN  1  Conversion complete interrupt enabled.
Bit 4:0  ADCH  00001  Input channel 1 selected as ADC input channel.

**ADC_R0**

Holds results of conversion. Read high byte (ADCRHA) before low byte (ADCRLA) so that conversion data cannot be overwritten with data from the next conversion.

**ADC_CV**

Holds compare values when compare function enabled.

![Initialization Flowchart for Example](image)

**Figure 66-5. Initialization Flowchart for Example**

### 66.7 Application Information

This section contains information for using the ADC module in applications. The ADC has been designed to be integrated into a microcontroller for use in embedded control applications requiring an A/D converter.

#### 66.7.1 Sources of Error

Several sources of error exist for A/D conversions. These are discussed in the following sections.
66.7.1.1 Sampling Error

For proper conversions, the input must be sampled long enough to achieve the proper accuracy. Given the maximum input resistance of approximately 7kΩ and input capacitance of approximately 1.3 pF, sampling to within 1/4LSB (at 12-bit resolution) can be achieved within the nominal sample window (6 cycles @ 40 MHz maximum ADCK frequency) provided the resistance of the external analog source (R_AS) is kept below 4 kΩ.

Higher source resistances or higher-accuracy sampling is possible by setting ADLSMP and changing the ADSTS bits (to increase the sample window) or decreasing ADCK frequency to increase sample time.

66.7.1.2 Pin Leakage Error

Leakage on the I/O pins can cause conversion error if the external analog source resistance (R_AS) is high. If this error cannot be tolerated by the application, keep R_AS lower than V_DDAD / (2^N * I_LEAK) for less than 1/4LSB leakage error (N = 8 in 8-bit, 10 in 10-bit or 12 in 12-bit mode).

66.7.1.3 Noise-Induced Errors

System noise that occurs during the sample or conversion process can affect the accuracy of the conversion. The ADC accuracy numbers are guaranteed as specified only if the following conditions are met:

- There is a 0.1 µF low-ESR capacitor from V_REFH to V_REFL.
- There is a 0.1 µF low-ESR capacitor from V_DDAD to V_SSAD.
- If inductive isolation is used from the primary supply, an additional 1 µF capacitor is placed from V_DDAD to V_SSAD.
- V_SSAD (and V_REFL, if connected) is connected to V_SS at a quiet point in the ground plane.
- Operate the MCU in wait or stop mode before initiating (hardware triggered conversions) or immediately after initiating (hardware or software triggered conversions) the ADC conversion.
• For software triggered conversions, immediately follow the write to ADCSC1 with a wait instruction or stop instruction.

• For stop mode operation, select ADACK as the clock source. Operation in stop reduces $V_{DD}$ noise but increases effective conversion time due to stop recovery.

• There is no I/O switching, input or output, on the MCU during the conversion.

There are some situations where external system activity causes radiated or conducted noise emissions or excessive $V_{DD}$ noise is coupled into the ADC. In these situations, or when the MCU cannot be placed in wait or stop or I/O activity cannot be halted, these recommended actions may reduce the effect of noise on the accuracy:

• Place a 0.01 µF capacitor (CAS) on the selected input channel to $V_{REFL}$ or $V_{SS}$ (this improves noise issues, but affects the sample rate based on the external analog source resistance).

• Average the result by converting the analog input many times in succession and dividing the sum of the results. Four samples are required to eliminate the effect of a 1LSB, one-time error.

• Reduce the effect of synchronous noise by operating off the asynchronous clock (ADACK) and averaging. Noise that is synchronous to ADCK cannot be averaged out.

### 66.7.1.4 Code Width and Quantization Error

**Note**

This will remain the same as long as the result is rounded for 8 and 10-bit modes. If the result is truncated in 8/10b modes then they will match 12b mode where the quantization error is -1 to 0.

The ADC quantizes the ideal straight-line transfer function into 4096 steps (in 12-bit mode). Each step ideally has the same height (1 code) and width. The width is defined as the delta between the transition points to one code and the next. The ideal code width for an N bit converter (in this case N can be 8, 10 or 12), defined as 1LSB, is:

$$1\text{lsb} = \frac{(V_{REFH} - V_{REFL})}{2^N}$$

There is an inherent quantization error due to the digitization of the result. For 8-bit or 10-bit conversions the code transitions when the voltage is at the midpoint between the points where the straight line transfer function is exactly represented by the actual
transfer function. Therefore, the quantization error will be ±1/2 lsb in 8- or 10-bit mode. As a consequence, however, the code width of the first (0x000) conversion is only 1/2 lsb and the code width of the last (0xFF or 0x3FF) is 1.5 lsb.

For 12-bit conversions the code transitions only after the full code width is present, so the quantization error is -1 lsb to 0 lsb and the code width of each step is 1 lsb.

66.7.1.5 Linearity Errors

The ADC may also exhibit non-linearity of several forms. Every effort has been made to reduce these errors but the system should be aware of them because they affect overall accuracy. These errors are:

- Zero-scale error ($E_{ZS}$) (sometimes called offset) — This error is defined as the difference between the actual code width of the first conversion and the ideal code width (1/2 lsb in 8-bit or 10-bit modes and 1 lsb in 12-bit mode). If the first conversion is 0x001, the difference between the actual 0x001 code width and its ideal (1 lsb) is used.

- Full-scale error ($E_{FS}$) — This error is defined as the difference between the actual code width of the last conversion and the ideal code width (1.5 lsb in 8-bit or 10-bit modes and 1LSB in 12-bit mode). If the last conversion is 0x3FE, the difference between the actual 0x3FE code width and its ideal (1LSB) is used.

- Differential non-linearity (DNL) — This error is defined as the worst-case difference between the actual code width and the ideal code width for all conversions.

- Integral non-linearity (INL) — This error is defined as the highest-value the (absolute value of the) running sum of DNL achieves. More simply, this is the worst-case difference of the actual transition voltage to a given code and its corresponding ideal transition voltage, for all codes.

- Total unadjusted error (TUE) — This error is defined as the difference between the actual transfer function and the ideal straight-line transfer function and includes all forms of error.

66.7.1.6 Code Jitter, Non-Monotonicity, and Missing Codes

Analog-to-digital converters are susceptible to three special forms of error. These are code jitter, non-monotonicity, and missing codes.
Code jitter is when, at certain points, a given input voltage converts to one of two values
when sampled repeatedly. Ideally, when the input voltage is infinitesimally smaller than
the transition voltage, the converter yields the lower code (and vice-versa). However,
even small amounts of system noise can cause the converter to be indeterminate (between
two codes) for a range of input voltages around the transition voltage. This range is
normally around ±1/2 lsb in 8-bit or 10-bit mode, or around 2 lsb in 12-bit mode, and
increases with noise.

This error may be reduced by repeatedly sampling the input and averaging the result.
Additionally the techniques discussed in Noise-Induced Errors reduces this error.

Non-monotonicity is defined as when, except for code jitter, the converter converts to a
lower code for a higher input voltage. Missing codes are those values never converted for
any input value.

In 8-bit or 10-bit mode, the ADC is guaranteed to be monotonic and have no missing
codes.

### 66.8 Memory map and register definition

The ADC-Digital contains 32-bit, word aligned, byte enables registers; byte or half word
access are not supported. All configuration registers are accessible via 32-bit access bus
Interface. Write access to reserved locations have no impact while read access to reserved
locations always return 0.

**NOTE**

No protection or indication mechanism is available (for example, 32-bit access starting with address offset value 0x01
or 0x02 or 0x03). The ADC does not check for correctness of
the programmed values in the registers and the programmer
must ensure that correct values are being written.

### 66.8.1 Control register for hardware triggers (ADCx_HC0)

ADC_HC0 can be used for both software and hardware trigger mode. Other ADC_HCn \((n = 1...)\) are for use only in hardware trigger mode. The ADC_HC0 to ADC_HCn \((n = 1...)\) registers have identical fields, and are used to control ADC operation. At any one point in time, only one of the ADC_HC0 to ADC_HCn \((n = 1...)\) registers is actively controlling ADC conversions. Updating ADC_HC0 while ADC_HCn \((n = 1...)\) is actively controlling a conversion is allowed (and vice-versa for any of the ADC_HCn \((n = 1...)\) registers). Writing ADC_HC0 while ADC_HC0 is actively controlling a conversion aborts the current conversion. In software trigger mode (ADTRG=0), writes to ADC_HC0 subsequently initiates a new conversion (if the ADCH bits are equal to a value other than all 1s). Similarly, writing any of the ADC_HCn \((n = 1...)\) registers while that specific ADC_HCn register is actively controlling a conversion aborts the current conversion. ADC_HCn \((n = 1...)\) register is not used for software trigger operation and therefore writes to any of them do not initiate a new conversion.

Adapted from the i.MX RT1060 Processor Reference Manual, Rev. 2, 12/2019.
66.8.2 Control register for hardware triggers (ADCx_HCn)

ADC_HCn (n = 1...) are for use only in hardware trigger mode. The ADC_HC0 to ADC_HCn registers have identical fields, and are used to control ADC operation. At any one point in time, only one of the ADC_HC0 to ADC_HCn registers is actively controlling ADC conversions. Updating ADC_HC0 while ADC_HCn is actively controlling a conversion is allowed (and vice-versa for any of the ADC_HCn registers). Writing any of the ADC_HCn registers while that specific ADC_HCn register is actively controlling a conversion aborts the current conversion. Any of the ADC_HCn (n = 1...) registers are not used for software trigger operation and therefore writes to any of them do not initiate a new conversion.

Conversion Complete Interrupt Enable/Disable Control

An interrupt is generated whenever ADC_HS[COCO0]=1(conversion ADC_HC0 completed), provided the corresponding interrupt is enabled.

0 Conversion complete interrupt disabled
1 Conversion complete interrupt enabled

This 5-bit field selects one of the input channels. The successive approximation converter subsystem is turned off when the channel select bits are all set (ADCH =11111b). This feature allows for explicit disabling of the ADC and isolation of the input channel from all sources. Terminating continuous conversions this way prevents an additional single conversion from being performed.

00000-01111 External channels 0 to 15

See External Signals for more information

66.8.3 Status register for HW triggers (ADCx_HS)

Bit 0 is used for both software and hardware trigger modes of operation. Bit 1 to bit (n-1) indicate the rest of the HW triggers' statuses similar to bit 0, potentially corresponding to multiple ADC_HC registers (for use only in hardware trigger mode).

### ADCx_HS field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–2</td>
<td>This read-only field is reserved and always has the value 0.</td>
</tr>
<tr>
<td>Reserved</td>
<td>This field is reserved.</td>
</tr>
<tr>
<td>0</td>
<td>Conversion Complete Flag</td>
</tr>
<tr>
<td>COCO0</td>
<td>The COCO0 flag is a read-only bit that is set each time a conversion is completed when the compare function is disabled (ADC_GC[ACFE]=0) and the hardware average function is disabled (ADC_GC[AVGE]=0). When the compare function is enabled (ADC_GC[ACFE]=1), the COCO0 flag is set upon completion of a conversion only if the compare result is true. When the hardware average function is enabled (ADC_GC[AVGE]=1), the COCO0 flag is set upon completion of the selected number of conversions (determined by the ADC_CFG[AVGS] field). The COCO0 flag will also set at the completion of a Calibration and Test sequence. A COCO0 bit is cleared when the respective ADC_HCn is written or when the respective ADC_Rn is read.</td>
</tr>
</tbody>
</table>

**NOTE:**
- In the hardware trigger mode, when trigger comes from TSC, COCO bit can be cleared by writing TSC register. When other ADC_ETC trigger sources work as ADC hardware trigger, COCO bit is cleared automatically when each phase is done.
- In the software trigger mode, COCO0 bit is cleared when ADC_HC0 is written or when ADC_R0 is read.
66.8.4 Data result register for HW triggers (ADCx_R0)

Contains the result of an ADC conversion of the channel selected by the respective hardware trigger and channel control register (ADC_HC0:ADC_HCn). For every ADC_HC0:ADC_HCn status and channel control register, there is a respective ADC_R0:ADC_Rn data result register. Unused bits in the ADC_Rn register are cleared in unsigned right justified modes. For example when configured for 10-bit single-ended mode, D[31:10] are cleared. The table below describes the behavior of the data result registers in the different modes of operation.

</tbody>
</table>

- **Reserved**: This read-only field is reserved and always has the value 0.
- **CAL**: CAL begins the calibration sequence when set. This bit stays set while the calibration is in progress and is cleared when the calibration sequence is complete. The ADC_GS[CALF] bit must be checked to determine the result of the calibration sequence. After it has started, the calibration routine cannot be interrupted by writes to the ADC registers or the results will be invalid and the ADC_GS[CALF] bit will set. Setting the CAL bit will abort any current conversion.
- **ADCO**: Enables continuous conversions.
  - 0: One conversion or one set of conversions if the hardware average function is enabled (AVGE=1) after initiating a conversion.
  - 1: Continuous conversions or sets of conversions if the hardware average function is enabled (AVGE=1) after initiating a conversion.
- **AVGE**: Enables the hardware average function of the ADC.
  - 0: Hardware average function disabled
  - 1: Hardware average function enabled

### ADCx_GC field descriptions (continued)

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| 4 ACFE | Compare Function Enable  
Enables the compare function.  
0 Compare function disabled  
1 Compare function enabled |
| 3 ACFGT | Compare Function Greater Than Enable  
Configures the compare function to check the conversion result relative to the compare value register (ADC_CV) based upon the value of ACREN (bit 2 in ADC_GC register). The ACFE bit must be set for ACFGT to have any effect.  
0 Configures "Less Than Threshold, Outside Range Not Inclusive and Inside Range Not Inclusive" functionality based on the values placed in the ADC_CV register.  
1 Configures "Greater Than Or Equal To Threshold, Outside Range Inclusive and Inside Range Inclusive" functionality based on the values placed in the ADC_CV registers. |
| 2 ACREN | Compare Function Range Enable  
Configures the compare function to check the conversion result of the input being monitored is either between or outside the range formed by the compare values in register (ADC_CV) determined by the value of ACFGT. The ACFE bit must be set for ACFGT to have any effect.  
0 Range function disabled. Only the compare value 1 of ADC_CV register (CV1) is compared.  
1 Range function enabled. Both compare values of ADC_CV registers (CV1 and CV2) are compared. |
| 1 DMAEN | DMA Enable  
Enables the DMA logic.  
0 DMA disabled (default)  
1 DMA enabled |
| 0 ADACKEN | Asynchronous clock output enable  
Enables the ADC's asynchronous clock source and the clock source output regardless of the conversion and input clock select (ADC_CFG[ADICLK]) settings of the ADC. Based on MCU configuration, the asynchronous clock may be used by other modules (see module introduction section). Setting this bit allows the clock to be used even while the ADC is idle or operating from a different clock source. Also, latency of initiating a single or first-continuous conversion with the asynchronous clock selected is reduced since the ADACK clock is already operational.  
0 Asynchronous clock output disabled; Asynchronous clock only enabled if selected by ADICLK and a conversion is active.  
1 Asynchronous clock and clock output enabled regardless of the state of the ADC |
66.8.8 General status register (ADCx_GS)

Controls the calibration, continuous convert, hardware averaging functions, conversion active, hardware/software trigger select, compare function and voltage reference select of the ADC module.

### 66.8.9 Compare value register (ADCx.CV)

Contains compare values used to compare with the conversion result when the compare function is enabled (ADC_GC[ACFE]=1). The compare values are right justified. Therefore, the compare function only uses the compare value register bits that are related to the ADC mode of operation. (e.g. in 8 bit mode, CV1 = ADC_CV[7:0] and CV2 = ADC_CV[23:16], similarly in 10 bit mode, CV1 = ADC_CV[9:0] and CV2 = ADC_CV[25:16] etc.) The compare value 2 in this register is utilized only when the compare range function is enabled (ADC_GC[ACREN]=1).

This read-only field is reserved and always has the value 0.

This read-only field is reserved and always has the value 0.

Contains a compare value used to compare with the conversion result when the compare function and compare range function are enabled (ADC_GC[ACFE]=1, ADC_GC[ACREN]=1).

Contains a compare value used to compare with the conversion result when the compare function is enabled (ADC_GC[ACFE]=1).
66.8.10 Offset correction value register (ADCx_OFS)

Contains the user-defined offset error correction value. This register is 13 bits wide. The value in the most significant bit (13th bit) is the operation bit. If this bit is ‘0’ then the value in the other 12 bits is added with the converted result value to generate final result to be loaded into ADC_Rn; if this bit is ‘1’ then this field is subtracted from converted value to generate final result (ADC_Rn).

66.8.11 Calibration value register (ADCx_CAL)

Contains calibration information that is generated by the calibration function. This register contains a calibration value of four bits(CAL[3:0]); this is automatically set after the self calibration sequence is done (ADC_SC[CAL] bit is cleared). If this register is written to by the user after calibration, the linearity error specifications may not be met.

67.2 About this module

67.2.1 Introduction

The ADC_ETC module enables multiple users to share the ADC modules in a TIME-Division-Multiplexing (TDM) way. The external triggers can be from the Cross BAR (XBAR) and TSC (Touch Screen Controller) in SOC. The ADC_ETC has one TSC external trigger and 8 external triggers from XBAR. The TSC external trigger is shared by TSC0 and TSC1. The triggers trig0~trig3 from XBAR and TSC0 belong to channel 0 and control ADC1, and trig4~trig7 and TSC1 belong to channel 1 and share ADC2 with the TSC external trigger. When TSC_BYPASS is set, TSC external trigger will control ADC2 directly. The ADC_ETC also supports SyncMode. When set as SyncMode, the ADC_ETC trigger source will controls ADC1 and ADC2 synchronously. In SyncMode,
the initial delay is controlled by the registers of trig0~trig3, while other settings are
independent. The SyncMode can not be used when TSC_BYPASS is active. The
ADC_ETC can support interrupt mode and DMA mode (controlled independently).

67.2.2 Features

The ADC_ETC includes the following features:

- ADC trigger control interface with dual ADCs, support up to 8 Hardware External
  Trigger (ext_hwts[7:0]) control for each ADC

- Capable of triggering dual ADC in SyncMode or AsyncMode:
  - In SyncMode ADC1 and ADC2 are controlled by the same trigger source of
    ADC_ETC.
  - In AsyncMode ADC1 and ADC2 are controlled by separate trigger source of
    ADC_ETC.

- Support up to four external trigger inputs for each ADC (trig0~trig3 for ADC1, and
  trig4~trig7 for ADC2):
  - Four single to multiple (up to 8) trigger sources. One external trigger of
    ADC_ETC results in multiple sequential triggers, which are named as trigger
    chain, to ADC.
  - Flexible ADC trigger interval and initial delay control.
  - Each trigger sources can be configured as HW or SW trigger mode.

- ADC result holding and status reporting

- External trigger auto hold and arbitration
  - Each external trigger can be configured with a fixed priority. External trigger
    with the highest priority is severed first.
  - Hold one trigger event upon arbitration lose or ADC busy.

- Support ADC trigger interface cascading

- Support interrupt mode. When interrupt mode is selected and one ADC conversion is
done, an interrupt request signal will be generated on one of the Done0~Done2
interrupt outputs.

- Support DMA mode. When DMA is enabled and one ADC conversion is done, a
  DMA request will be sent. 2 trigger modes of DMA can be selected by configuring
  DMA_MODE_SEL bitfield.
67.3 Block diagram

Figure 67-1. ADC_ETC block diagram

67.4 Functional description

The ADC_ETC block works with XBAR and TSC blocks to share with the ADC modules. The following sections describe functional details of the ADC_ETC module.
67.4.1 Clocks

The ADC_ETC module has one global functional clock: ipg_clk. The ipg_clk is used for register read/write operations, also all the functionality inside the ADC_ETC module are synchronized to this clock.

As XBAR and TSC input can be SYNC or ASYNC with the ADC_ETC clock, the ipg_clk need to be set that can capture the trigger input edge after the double synchronous circuit.

67.4.2 Reset

The ADC_ETC has two resets: ipg_hard_async_reset_b and sw_reset_n. The ipg_hard_async_reset_b is a hardware reset, which resets all registers in ADC_ETC block. While the sw_reset_n is a software reset, which can reset all configuration registers by software.

67.4.3 Operations

This section describes the ADC_ETC module’s operations.

The trigger process is used to process the multiple input sources, trigger_enable can be used to mask the hardware trigger source. Software can select the hardware trigger or software trigger by configuration, and the selected source is double synchronized and the posedge pulse is detected before a request is sent to the arbiter.

The trigger process diagram is indicated as below:
The trigger requests from XBAR and TSC have fixed priority setting before going to the arbiter. There are total of eight priority levels available for each trigger request, where 7 is the highest priority level and 0 is the lowest priority level. If multiple trigger requests have the same priority level, then the round-robin scheme is applied for the requests to the ADC trigger source. The trigger request is granted only when the previous trigger has finished and the ADC module is IDLE. When in SYNC mode, the trigger request is granted only when both ADC modules are IDLE state.

When there is a trigger request that is granted, the ADC_ETC sends several triggers as a chain of trigger, with HWTS[7:0] as corresponding hardware trigger select signal, and with CSEL[3:0] configuring the sampled channel of the ADC. When the ADC finishes conversion, the ADC sends back a complete signal adc_coco to the ADC_ETC, which has the same width as HWTS and indicates the ADC hardware trigger corresponding with the current sar_result_o, then the ADC_ETC stores the correct ADC converted results into the internal registers, and clear the ADC COCO signals in the correct order. All parts of these steps are automatically done by hardware. At the same time, interrupt asserts according to the software configuration. After that, the next trigger is sent after a configurable interval delay, until all triggers in the chain are processed. When complete the the last trigger in chain, ADC_ETC sends the coco signal to mark the end of one of ADC_ETC external trigger, and a DMA request is launched according to the software configuration.

Each ADC trigger in the trigger chains, initiated by the eight external trigger sources, has separate configurations by software, including Interrupt selection (IE), Back to Back ADC trigger (B2B), HWTS and CSEL to ADC. The ADC_ETC have interrupt outputs of Done0, Done1, Done2 and Error Interrupt. The Done0/1/2 interrupts are controlled by software for each ADC trigger. IEx selects which port the interrupt occurs on. (IEx=2'b00
means no interrupt, while 2'b01~2'b11 mean selecting Done0~Done2 correspondingly). Error interrupt occurs when there is an external trigger ignored by ADC_ETC due to the previous trigger not finished yet.

The ETC ADC interface timing is indicated in below diagrams:

![ETC ADC interface timing diagram]

**Figure 67-3. ETC ADC interface timing**

Waiting Initial delay after external trigger from XBAR, the trigger_req asserts. After one ADC conversion, the next trigger in the chain starts as soon as possible if B2B is enabled. Otherwise the next trigger does not start until after a interval delay. The length of Initial delay and Interval delay are configurable, the relationship between these 2 delays and the register setting is described in the description of the ETC_TRIG counter.

### 67.5 Memory Map and register definition

This section includes the ADC_ETC module memory map and detailed descriptions of all registers.

68.2 Overview

This block describes the Touch Screen Controller (TSC), which is used for ADC and touch screen analogue block.

TSC is responsible for providing control of ADC and touch screen analogue block to form a touch screen system, which achieves function of touch detection and touch location detection. The controller utilizes ADC hardware trigger function and control switches in touch screen analogue block. The controller only supports 4-wire of 5-wire screen touch modes.

Figure 68-1. TSC block diagram
68.2.1 Features

The features of TSC controller are following.

- Configure registers: 32-bit, fully support sky-blue bus interface
- 4-wire or 5-wire mode of touch screen
- Low power wake up functions
- ADC average function and custom 8-bit, 10-bit, and 12-bit conversion result
- Custom pre-charge and de-glitch threshold time setting
- Total control five analogue groups of switches
- Fully asynchronous interface to ADC and analogue switches
- Easy software operation
- Software takes control of operation flow
- Strong debug functions—enable software recognize the IP as a transparent box and operation output directly
- Software reset function
68.3 Functional Description

This block works with ADC and TSC analogue to form a touch screen system. The system is responsible to detect touch on screen and measure the coordinate of the touch point. The touch screen controller, which is at the heart of the system, given control to TSC analogue and ADC. TSC analogue provides positive or negative voltage to the screen if the touch screen controller provides relevant signals. The ADC convert coordinates value if requested by touch screen controller.

68.3.1 Operating modes

The TSC can be worked in the following modes.

68.3.1.1 Idle

The TSC always stays at idle status if finish a coordinate measurement. The TSC only starts to detect a touch or starts to measure coordinate value if set the start_sen bit. The TSC returns to idle status after finish current task if disable bit is set by software.

68.3.1.2 Pre-charge

Pre-charge is a preparation for detection stage. Before detection stage, the upper layer of screen is required to charge to positive high. The time required for the pre-charge can be set in the pre-charge_timer.

68.3.1.3 Detection

Detection is a stage to sense touch detect on the screen. This stage is initialed a delay (set by pre-charge_timer) in order to wait enough time for the lower screen layer to achieve even-potential status. After the TSC send out detect enable signal to detect signal from analogue, after receiving the signal, TSC starts to measure coordinates or waiting for the instruction from software according to the value of auto_measure. If auto_measure is set then the TSC automatically measures coordinates after detect a touch. Otherwise TSC
waits for software order after detects a touch (and generates an interrupt). The software can choose to drop the measure (and return back to idle) by setting drop_measure, or start the measure by setting start_measure.

### 68.3.1.4 Measurement

During the measure stage, the TSC hardware gives control to TSC analogue and ADC. No software operation is needed. If requesting average function, do average configuration for ADC.

### 68.3.1.5 Data valid check

After measure the coordinate value, TSC do a touch detects again. If no touch has been detected, then previous measured coordinates’ value is invalid. Otherwise, the measured coordinates’ value is valid.

### 68.3.1.6 Interrupt

Each interrupt provides three software interface bits: interrupt enable, interrupt signal enable, and interrupt signal.

### 68.3.1.7 Reset

The TSC has two resets: ipg_reset_b and sw_rst. The ipg_reset_b reset is a hardware reset, which resets all registers in TSC block. While the sw_rst is a software reset, which resets every register except ips directly access ones.

### 68.3.1.8 Debug mode

The TSC provides fully software control signals. After debug_en has been set, then all TSC outputs will be controlled by software. Software can also observe all TSC inputs through debug interface. Furthermore, the debug registers also provides current state machine states. Software can always check the current hardware state.
68.3.2 Configuration

68.3.2.1 TSC configurations

The following tables provide 4-wire and 5-wire screen touch modes.

</tr>
<tr>
<td>xpu_l_pull_down</td>
<td>pd_en</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

68.3.2.4 TSC and GPIO

From TSC point of view, it does not care what kinds of PAD used. It can use digital pad or analogue pad.
Table 68-7. The ports used in TSC and GPIO

<table>
<thead>
<tr>
<th>TSC function ports</th>
<th>TSC analogue instance</th>
<th>ADC Ain pin</th>
<th>GPIO ports</th>
</tr>
</thead>
<tbody>
<tr>
<td>wiper</td>
<td>1</td>
<td>Ain [0]</td>
<td>GPIO_AD_B1_11</td>
</tr>
<tr>
<td>ynlr</td>
<td>2</td>
<td>Ain [1]</td>
<td>GPIO_AD_B1_12</td>
</tr>
<tr>
<td>ypll</td>
<td>3</td>
<td>Ain [2]</td>
<td>GPIO_AD_B1_13</td>
</tr>
<tr>
<td>xnur</td>
<td>4</td>
<td>Ain [3]</td>
<td>GPIO_AD_B1_14</td>
</tr>
<tr>
<td>xpul</td>
<td>5</td>
<td>Ain [4]</td>
<td>GPIO_AD_B1_15</td>
</tr>
</tbody>
</table>

**NOTE**

For the PAD used for TSC, make sure the PAD behavior, such as a wire only connects to the Pin and TSC analogue switches.

For the PAD used for GPIO, for example, has a keeper to prevent the GPIO pad working from a wire only connects the Pin and TSC. In such condition, disable keeper when TSC working.

### 68.3.2.5 ADC-TSC co-working

The TSC is designed to work with the ADC. Two IP must work together to achieve the correct functions. The coordinate work includes two steps:

1. TSC starts ADC

   TSC sends two signals: trigger and hardware trigger select signal: HWTS[4:0].

   ADC regards triggers as clock to capture the select signal: HWTS. The details of information about trigger and HWTS is show in the ADC hardware trigger chapter. The TSC hardware makes sure that the HWTS signals ready one clock cycles before sending trigger signals. Make sure that the trigger delay is less than HWTS delay + one clock cycle.

   The TSC send HWTS as in the following table:

<table>
<thead>
<tr>
<th></th>
<th>TSC 4-wire mode</th>
<th>TSC 5-wire mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-coordinate measure</td>
<td>HWTS = 5'b01000</td>
<td>HWTS = 5'b10000</td>
</tr>
<tr>
<td>y-coordinate measure</td>
<td>HWTS = 5'b00010</td>
<td>HWTS = 5'b10000</td>
</tr>
</tbody>
</table>
TSC HWTS[4:0] connects to the ADC HWTS[4:0]. The integration change will lead change in driver implementation. On ADC side, HWTS = 1 << x indicates the x logic channel is selected to start hardware ADC conversion. Configure ADC_HCx to configure x logic channel and conversion will store in ADC_Rx.

Each ADC hardware trigger logic channel can be configured to one of many physical channels. The details of the ADC configuration, refer to the ADC hardware trigger chapter. Software driver configures the physical ADC. A sample configuration is shown in the following table.

<table>
<thead>
<tr>
<th></th>
<th>TSC 4-wire mode</th>
<th>TSC 5-wire mode</th>
</tr>
</thead>
<tbody>
<tr>
<td>x-coordinate measure</td>
<td>ADC measures channel 1 or 2, so configure ADC_HC3[ADCH] to 1 or 2.</td>
<td>ADC measure channel 0, so configure ADC_HC[4] to 0.</td>
</tr>
<tr>
<td>y-coordinate measure</td>
<td>ADC measures channel 3 or 4, so configure ADC_HC[1][ADCH] to 3 or 4.</td>
<td>ADC measures channel 0, so configure ADC_HC[4] to 0.</td>
</tr>
</tbody>
</table>

Before TSC starts work, software driver configure ADC_HCx. TSC hardware automatically sends trigger and HWTS at the correct time.

2. ADC sends back converted value and complete signals to TSC. When ADC finishes conversion, the ADC would send a complete signal to TSC. A set of handshake signals between ADC and TSC makes sure that the TSC could receive complete signals, store correct ADC converted value, and clear ADC coco signals at correct order. All parts of this step are automatically done by hardware.

**NOTE**

For different ADC conversion modes, such 8-bit, 10-bit, 12-bit mode, average mode, please configure in ADC registers.

### 68.4 TSC Memory Map/Register Definition

The TSC Memory Map and Register Definition is described in the following section.

## TSC_DEBUG_MODE field descriptions

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>31–29 Reserved</td>
<td>This read-only field is reserved and always has the value 0.</td>
</tr>
</tbody>
</table>
| 28 DEBUG_EN | Debug Enable  
The RO registers in debug_mode and debug_mode2 always reflect the latest value and is not controlled by this bit. All RW SW bits are controlled by this bit.  
0 Enable debug mode  
1 Disable debug mode |
| 27 Reserved | This read-only field is reserved and always has the value 0. |
| 26 ADC_COCO_CLEAR_DISABLE | ADC COCO Clear Disable  
This bit could prevent TSC HW generates an ADC COCO clear signal.  
**NOTE:** This bit does not effect ADC_COCO_CLEAR bit.  
0 Allow TSC hardware generates ADC COCO clear  
1 Prevent TSC from generate ADC COCO clear signal |
| 25 ADC_COCO_CLEAR | ADC Coco Clear  
Original ADC coco only clear is system read conv result from IPS bus. However, TSC read conv result directly from ADC to lower SW load, so that ADC requires TSC generates a clear signal.  
0 No ADC COCO clear  
1 Set ADC COCO clear |
| 24 TRIGGER | Trigger  
Hardware trigger signal to ADC  
0 No hardware trigger signal  
1 Hardware trigger signal, the signal must last at least 1 ips clock period |
| 23–21 Reserved | This read-only field is reserved and always has the value 0. |
| 20–16 EXT_HWTS | Hardware Trigger Select Signal  
Hardware trigger select signal, select which channel to start conversion. |
| 15–13 Reserved | This read-only field is reserved and always has the value 0. |
| 12 ADC_COCO | ADC COCO Signal  
This signal is generated by ADC. |
| ADC_CONV_VALUE | ADC Conversion Value  
This signal is generated by ADC. |

11  
- Normal function: 0x3 ipg clock cycles;  
- Low power mode: 0x3 low power clock cycles |
| 28 DETECT_ENABLE_FIVE_WIRE | Detect Enable Five Wire  
0  
- Do not read five wire detect value, read default value from analogue  
1  
- Read five wire detect status from analogue |
| 27–25 Reserved | This read-only field is reserved and always has the value 0. |
| 24 DETECT_ENABLE_FOUR_WIRE | Detect Enable Four Wire  
0  
- Do not read four wire detect value, read default value from analogue  
1  
- Read four wire detect status from analogue |
| 23 INTERMEDIATE | Intermediate State  
It’s an intermediate state, between two state machine states, in order to provide better timing for analogue.  
It lasts for only one cycle. Intermediate state exists after pre-charge, detect, x-measure, y-measure, and 2nd-pre-charge, 2nd-detect. Note, the intermediate after pre-charge and 2nd-pre-charge is different.  
0  
- Not in intermediate  
1  
- Intermediate |
| 22–20 STATE_MACHINE | State Machine  
000  
- Idle  
001  
- Pre-charge  
010  
- Detect  
011  
- X-measure  
100  
- Y-measure  
101  
- Pre-charge  
110  
- Detect |
| 19–18 Reserved | This read-only field is reserved and always has the value 0. |
| 17 DETECT_FIVE_WIRE | Detect Five Wire  
This field in only valid when the touch controller is under detect mode. That is not in idle.  
NOTE: It is in measure mode, not pre-charge mode. This is an asynchronous signal.  
Table continues on the next page...

Appendix A
Revision History

The following table provides a revision history for this document.

<table>
<thead>
<tr>
<th>Rev. No.</th>
<th>Date</th>
<th>Substantial Changes</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>08/2018</td>
<td>Initial public release.</td>
</tr>
<tr>
<td>1</td>
<td>12/2018</td>
<td>Major revision upgrade: updates in several chapters, see &quot;Change summary&quot; in this specific revision for more details.</td>
</tr>
<tr>
<td>2</td>
<td>12/2019</td>
<td>Major revision upgrade: updates in several chapters, see &quot;Substantive changes&quot; below for more details.</td>
</tr>
</tbody>
</table>
Appendix B
Substantive changes for this revision

Substantive changes for this revision are as follows:

B.1 About this Document Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Suggested Reading</td>
<td>“About this document” chapter is optimized and split from “Introduction” chapter, as Chapter 1.</td>
</tr>
</tbody>
</table>

B.2 Introduction Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Block Diagram</td>
<td>Clarified GPIO1-5 as standard GPIOs and GPIO6-9 as high-speed GPIOs in the block diagram.</td>
</tr>
<tr>
<td>Features</td>
<td>Updated the “Features” section.</td>
</tr>
</tbody>
</table>

B.3 Memory Maps Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Arm Platform Memory Map</td>
<td>Minor updates in the “AIPS-1 memory map” table.</td>
</tr>
</tbody>
</table>
### B.4 Interrupts, DMA Events, and XBAR Assignments Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CM7 interrupts</td>
<td>New note added before the table “CM7 domain interrupt summary”.</td>
</tr>
<tr>
<td>PIT Channel Assignments For Periodic DMA Triggering</td>
<td>Added a new section “PIT Channel Assignments for Periodic DMA Triggering”.</td>
</tr>
<tr>
<td>XBAR Resource Assignments</td>
<td>Minor updates in the QTIMER rows of the table “XBAR1 Output Assignments”.</td>
</tr>
</tbody>
</table>

### B.5 DMA MUX Revision History

No substantive changes

### B.6 eDMA Revision History

No substantive changes

### B.7 System Security Revision History

Minor updates in this security overview chapter.

### B.8 System Debug Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Coresight Embedded Trace Buffer (ETB)</td>
<td>Some correction: section “Coresight Embedded Trace Buffer (ETB)” added back, and the section “Supported tools” removed.</td>
</tr>
</tbody>
</table>
B.9 System Boot Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chip-specific Boot Information</td>
<td>• Updated the table “ROM Bootloader Peripheral PinMux”.</td>
</tr>
<tr>
<td></td>
<td>• Extra notes added after the table “ROM Clock Setting”.</td>
</tr>
<tr>
<td>Boot eFUSE descriptions</td>
<td>Minor updates in the table “Boot eFUSE descriptions”.</td>
</tr>
<tr>
<td>Boot devices</td>
<td>Notes added after the table “Boot device selection”.</td>
</tr>
<tr>
<td>Serial NOR eFUSE Configuration</td>
<td>Minor updates in the table “Fuse definition for Serial NOR over FlexSPI”.</td>
</tr>
<tr>
<td>FlexSPI Serial NOR Flash Boot Operation</td>
<td>Note added in the section “FlexSPI Serial NOR Flash Boot Operation”.</td>
</tr>
<tr>
<td>Firmware Configuration Block</td>
<td>Minor updates in the table “Flash Control Block Structure”.</td>
</tr>
<tr>
<td>Expansion device eFUSE configuration</td>
<td>Updated the table “uSDHC eFuse Descriptions”.</td>
</tr>
<tr>
<td>Serial NOR/EEPROM eFUSE configuration</td>
<td>Minor updates in the table “Serial NOR/EEPROM boot eFUSE descriptions”.</td>
</tr>
<tr>
<td>Image vector table structure</td>
<td>Note added after the “IVT format” table.</td>
</tr>
<tr>
<td>Write data command</td>
<td>New table “Valid DCD address ranges” added in the section “Write data command”.</td>
</tr>
<tr>
<td>-</td>
<td>Removed the section “Unlock command”, which is not customer-facing content.</td>
</tr>
</tbody>
</table>

B.10 External Signals and Pin Multiplexing Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Muxing Options</td>
<td>Updated the FlexSPI2 rows, in the “Muxing Options” table.</td>
</tr>
</tbody>
</table>

B.11 IOMUXC Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IOMUXC Memory Map/Register Definition</td>
<td>• Some descriptions updated in the IOMUXC register parts.</td>
</tr>
<tr>
<td></td>
<td>• SW_MUX_CTL_PAD_GPIO_SPI_xx related registers removed, which are not applicable in this device.</td>
</tr>
</tbody>
</table>
B.12  GPIO Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chip-specific GPIO information</td>
<td>Clarified high-speed GPIOs (GPIO6-9) in the “Chip-specific GPIO information” section.</td>
</tr>
<tr>
<td>Operating Frequency</td>
<td>Added the table “IO Operating Frequency”.</td>
</tr>
</tbody>
</table>

B.13  Clock and Power Management Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>System domains layout</td>
<td>Updated the table “Low Power Mode Definition”.</td>
</tr>
</tbody>
</table>

B.14  CCM Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>External Signals</td>
<td>CCM_REF_EN_B row added in the “CCM External Signals” table.</td>
</tr>
<tr>
<td>CCM Clock Tree</td>
<td>Note added after the “Clock Tree - Part 2” figure.</td>
</tr>
<tr>
<td>System Clocks</td>
<td>Updated the “System Clock Frequency Values” table.</td>
</tr>
<tr>
<td>System PLL (PLL2)</td>
<td>Updated the section “System PLL (PLL2)”.</td>
</tr>
</tbody>
</table>

B.15  XTALOSC Revision History

No substantive changes

B.16  PMU Revision History

Removed the “Digital LDO Regulators” section, which is not applicable in the device.

B.17  GPC Revision History

No substantive changes
B.18  DCDC Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory Map and register definition</td>
<td>• In REG1, clarified VBG_TRIM, LOOPCTRL_HST_THRESH, REG_FBK_SEL bitfields.</td>
</tr>
<tr>
<td></td>
<td>• In REG2, clarified DCM_SET_CTRL, DISABLE_PULSE_SKIP bitfields. LOOPCTRL_DC_R and LOOPCTRL_DC_C bitfields now for internal audience only.</td>
</tr>
<tr>
<td></td>
<td>• In REG3, MISC_DISABLEFET_LOGIC and MISC_DELAY_TIMING are now reserved bitfields.</td>
</tr>
<tr>
<td></td>
<td>• Added a cross reference to CUR_SNS_THRSH in the CURRENT_ALERT_RESET bitfield.</td>
</tr>
</tbody>
</table>

B.19  TEMPMON Revision History

No substantive changes

B.20  SNVS Revision History

No substantive changes

B.21  SRC Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SRC</td>
<td>Updated the SRC_GPR10 register.</td>
</tr>
</tbody>
</table>

B.22  Fusemap Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Boot Fusemap</td>
<td>Updated the table “FlexSPI (Serial NOR) boot fusemap”.</td>
</tr>
<tr>
<td>Fusemap Descriptions Table</td>
<td>Minor updates in the table “Fusemap Descriptions”.</td>
</tr>
</tbody>
</table>
B.23  OCOTP Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>Latest content included, e.g. the section “OTP Read/Write Timing Parameters” refreshed.</td>
</tr>
</tbody>
</table>

B.24  External Memory Controllers Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
</table>
| Smart External Memory Controller (SEMC) Overview | Minor updates in this overview chapter, for example:  
  • NOR Flash and SRAM interface only supports 16-bit mode.  
  • High Function Block Diagram removed since the SEMC Chapter already has a block diagram. |

B.25  SEMC Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chip-specific SEMC information</td>
<td>Note added in the chip-specific SEMC info section.</td>
</tr>
<tr>
<td>-</td>
<td>Latest content included, e.g. some info clarified, also new sections “NOR Flash address map” and “SRAM Flash address map” added.</td>
</tr>
</tbody>
</table>

B.26  USDHC Revision History

No substantive changes

B.27  FlexSPI Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-</td>
<td>Latest content included, with some info clarified.</td>
</tr>
</tbody>
</table>
B.28  Arm Cortex M7 Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chip-specific Arm Cortex M7 information</td>
<td>Added information that there are 16 regions implemented in the MPU.</td>
</tr>
<tr>
<td></td>
<td>Added list of CoreSight components and their corresponding Arm documents.</td>
</tr>
</tbody>
</table>

B.29  NIC Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory Map and Register Definition</td>
<td>In the SIM_M registers table, fn_mod2 description corrected.</td>
</tr>
</tbody>
</table>

B.30  OCRAM Revision History

No substantive changes

B.31  FlexRAM Revision History

No substantive changes

B.32  AIPSTZ Revision History

No substantive changes

B.33  Display and Camera Overview Revision History

No substantive changes
### B.34 CSI Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>External Signals</td>
<td>Added note that the csi_hclk needs to be at least 10% faster than the pixel clock.</td>
</tr>
</tbody>
</table>

### B.35 eLCDIF Revision History

No substantive changes

### B.36 PXP Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Porter-Duff Alpha Blend</td>
<td>Formula added for image output and alpha output, in the section &quot;Porter-Duff Alpha Blend&quot;.</td>
</tr>
</tbody>
</table>

### B.37 Audio Overview Revision History

No substantive changes

### B.38 SAI Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chip-specific SAI information</td>
<td>Note added in the &quot;Chip-specific SAI information&quot; section.</td>
</tr>
</tbody>
</table>
| -                      | • Latest content included, with some info clarified.  
|                        | • The section "FIFO Combine" added back; also corrected the Data Register and FIFO Register numbers, as the number of TX and RX data lines for SAI1 and SAI2/SAI3 are 4 and 1 respectively. |

### B.39 MQS Revision History

No substantive changes
B.40  SPDIF Revision History
No substantive changes

B.41  ENET Revision History
No substantive changes

B.42  USB Revision History
No substantive changes

B.43  USB PHY Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>USB Analog Memory Map/Register Definition</td>
<td>Minor correction: USB_LOOPBACK registers added in the &quot;USB_ANALOG memory map&quot; section.</td>
</tr>
</tbody>
</table>

B.44  FLEXCAN Revision History

<table>
<thead>
<tr>
<th>Topic Cross-Reference</th>
<th>Change Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>External Signals</td>
<td>Minor correction in the RX and TX rows of the “FLEXCAN External Signals” table.</td>
</tr>
